There is a threefold motion; Violent, Animall, and Naturall: of violent motions none at all can bee perpetuall, whereupon wee may conclude that no Art can make a perpetuall motion. Animall motions are all voluntary: this *Galen* well describeth in the fifth Chapter of his second Booke *De motu musculorum*, where he sayth, If thou canst settle and appease those things that are moued or done at thy pleasure, and againe moue or doe that was at rest

rest or was not done, that action or motion is truly voluntary; if moreover thou canst doe any thing swifter or slower, oftner or seldomer at thy pleasure, these actions are obedient to thy will.

Natural motions manifold.

Finally, the Naturall motion is manifold, as a thing may diuers waies be said to be naturall. There is one simple naturall motion which is accomplished onely by Nature and the Elementary forme; with this motion heavy things moue downward, and light things vpward. Secondly, all motions are called Naturall which are opposed to violent motions; so the motions of the muscles, though they be voluntary, are said to be naturall, if they be naturally disposed. Thirdly, all motions are called Naturall which are not Animall, that is, voluntary: So *Galen* saith in the place before quoted, that the motion of the heart is not of the Soule, that is, of the will, but of Nature: and againe, the motion of the heart is of Nature, the motion of the chest, of the Soule.

The resolution of the question

So that *Galen* in his 7. Booke *de usu partium*, deliuering but two kinds of faculties, the one Animall, the other Naturall, vnderstandeth all that to be Naturall which is not Animall or voluntary. Now we conclude, that the motion of the heart is Naturall in the third acception; that is, that it dependeth neither vpon the will, nor simply vpon Nature; but vpon the vitall faculty of the Soule which is Naturall: not vpon the will, because wee can neither stay it nor set it going againe, neither slacken nor hasten it at our pleasure: not simply vpon Nature, for in a body that is animated, that is, that hath a Soule, nothing moueth but the Soule, otherwise there should bee more formes then one, and more beginners of motion then one, which true and solide Philosophy will not suffer. This Soule is the Nature it selfe of the Creature, which that it may preserve the vnion betweene the body and it selfe, moueth the heart, concocteth in the Stomacke, reboyleth in the Liuer, and perfecteth the blood in the Veines. When wee say therefore that the motion of the heart is Naturall, we meane that it is from a Naturall faculty of the Soule which is not voluntary. And that this motion is Naturall, all the causes of it do evidently shew.

Three immediate causes of the pulse.

There bee three immediate causes of the pulse, the Efficient, the End or finall cause, and the Instrument, all Naturall.

The Efficient.

The Efficient cause is the vitall faculty, which imploiethe it selfe wholly about the generation of spirits, which by that perpetual motion are brought forth, for in the *Diastole* or dilatation it draweth blood & ayre. In the *Systole* or contraction it driueth out the spirits already made, and their excrements.

The Finall.

The Finall cause (which you may call either the vse or the necessity at your pleasure,) is three-fold; the nourishment of the spirituous substance, which is kept in the left ventricle of the heart; the tempering and moderating of it (for there was great danger, that because of the continuall motion the heart should be inflamed, vnlesse it had bene ventilated with ayre as with a fan) and the expurgation of smoky or fumed vapors.

The Instrument.

The Instruments also of this motion are Naturall, not Animall. *Galen* calleth the Animall Instruments, the Muscles and the Nerves: the heart is no muscle, vnlesse we speake abusively, because of the fastnes and colour of his flesh; and for nerves there are none that reach vnto his ventricles. There is indeed a small surcle or tendrill from the sixth coniugation that maketh the Recurrent, which is disseminated in the purse and Basis of the Heart, but the Heart standeth in no need of it for his motion; for if this nerue be intercepted with a string, or (which is the surest way) his originall, which is easily perceived by the sides of the weazon; yet neuertheless is the heart moued as also the arteries, as in *Dogges* wee haue often made experiment. Seeing therefore all the causes of the hearts motion be Naturall, we may conclude that it selfe is Naturall, coming from the vitall faculty which is not voluntary.

The first obiection.

But that the truth of this conclusion may more plainly appeare, some obiections must be answered, which otherwise would breede scruple in the mindes of them that are not sufficiently grounded in these secrets of Nature.

Answered.

First therefore say some, all naturall motions are continuall; but the motion of the heart is interrupted with a double rest, one betweene each motion. Let vs admit that one simple Naturall motion is continuall: yet when there are two naturall motions and those contrary, there must needs be a rest betweene them.

The second. Answered.

Secondly, they say, no naturall motion is compound: but the motion of the heart is compound. I answer, The motion of the heart is not compound, but double not simple; because of two contrary motions cannot be made one compound motion; neither of many motions is made one motion as one line of many points.

Thirdly,

Thirdly, they vrge vs further thus, with *Aristotle* in the 7. Booke of his *Metaph.* Whatsoever is moued by Nature is moued to some end, which end when it hath obtained, then it resteth; as water being heated, if by it owne force and proper forme it be cooled, it neuer groweth hot againe by the same forme or force. Wherefore if the heart be moued naturally, it is moued that it may be dilated or contracted; when therefore it is dilated, why is it contracted? and when it is contracted, why is it dilated againe? I answered, that that is true in a motion that is purely and meere natural; but the motion of the heart is from the vitall faculty of the Soule, which hath a naturall instinct and knowledge of his own vse, and according to the diuers appetites of that naturall instinct moueth diuersly. For when the heart is contracted, it desireth to be dilated that it may draw in cold ayre, when it is dilated or distended, it desireth to be contracted to auoide the smoke and soote that by his heate are ingendred: so the vitall facultie of the Soule which is sensible of his owne want, moueth the heart perpetually with diuers motions, according as the needs of the Soule do require. By which this motion of the heart is distinguished from other motions of the naturall faculty of the Soule, to wit, of the wombe and the stomacke. For the motion of these parts is not perpetuall, because there wanteth a perpetuall object, neither doth any necessity vrge, the finall cause it is not alwaies at hand, but the heart hath a continuall object, necessity and end: for it wanteth perpetuall nourishment, tempering and expurgation. Finally, they contend that the motion of the hart is not naturall, because it is to two contrary points, but opposite and contrary motions are onely performed by the Animall faculty: so the arme is lifted vp and pulled down onely by the will. I answered, that in things without life this is true, but all things that haue life, yea even in plants themselves there is motion to contrary points. I say more, there is neuer in the Soule one motion, but presently resulteth another opposite or contrary vnto it: so in nutrition, the attraction of the Aliment is from the Soule, so is also the expulsion of excrements from the same Soule. The Soule is so diuine a thing, that not onely it doth many things beside the laws of other formes, but also is the author of contraries; for it moueth vpward and downward and beyond the Nature of Elements, to the right hand, to the left, and circularly. The motion of the earth is simple and vniforme, the motion of the Soule manifold, because the forme of the earth is one and simply simple. The Soule is simple, manifold, and manifold waies: Simple in his Essence, manifold in his Power and Vertue, and manifold waies in his knowledge of objects, from which his operations and actions are drawne.

We therefore conclude that the motion of the heart is Naturall, and proceedeth from the vitall faculty for a certaine end and purpose of Nature, and that it doth so proceede, these two arguments doe necessarily conuince.

First, because in the dilatation there is a certaine and determinate kinde of bloud and ayre drawne perpetually through the same set and determinate vessels. In the contraction likewise the smoky ayre and the spirits are thrust out by certaine vessels.

Secondly, because the flesh of the heart is wouen with all kinds of fibres. If therefore those seuerall fibres doe in other parts some draw, some contract, and some loosen, either they are superfluous in the heart (which to say, is to blaspheme Nature) or else they haue the same vses in the heart that they haue in other parts. We said it proceeded for a certaine end, because this faculty neither worketh voluntarily as the Animall, nor according to the power of the Agent in respect of that which suffereth, but for meere necessity. The stomack, although it be not hungry, yet it concocteth so much meat as is put into it, if it can: but the heart is not moued but as necessity vrgeth, making a pulse either swifter or slower, as the vse of Nature is to haue a flow or quick pulse.

QUEST. III.

Of the manner of the motion of the Heart, and whether it strike the
Brest in the dilatation or in the contraction.

Hus much concerning the cause of the motion of the heart. It followes now to speak of the manner of his motion, which is better knowne by the eye then by discourse of reason: wherefore it is vsuall with Anatomists, for the better obseruation of this motion, to open Dogs aliue, that they may more distinctly see the manner thereof. From this *Anatomy* and witnesse of the eye will we vnfold this mystery.

The third.

Answer.

How the motion of the heart differeth from that of other parts.

The fourth.
Answer.

The diuinity of the Soule.

Multiplicity.

The conclusion.

The manner of the motion of the heart.

There

The 2. motions of the heart.
The double rest how necessary.

There are two motions of the heart. *Dyaftole* or dilatation, and *Systole* or contraction; betwixt each of these is a rest or cessation, one following the distention, the other following the contraction. For it is not possible that two contrary motions should immediately succeed one another: but in the poynt of the refluxion or returne from one contrary to another there must needs be a rest, otherwise there could be no beginning nor end of one motion distinct from the beginning and end of another; and so the motions could not bee contrary which had no distinct beginning nor end particular to either of them, because there is no rest from which the beginning of the motion should arise, or into which the end of the motion should determine: wherefore whatlocuer hath any reflexion, hath also some rest before the reflexion.

An instance in the tyde.

A manifest instance hereof we haue in the Tyde, which when it hath flowed to his height, standeth some small time at a stay before it begin to Ebbe, which stay we call a high water when no motion of the tide can be perceived. But what is done in these contrary motions?

Dyaftole what.

In the *Dyaftole* the heart draweth blood by the gate of the hollow veine into his right ventricle, and ayre by the arteriall veine into the left. In the *Systole* the heart driueth out vitall spirits into the great artery, or fumed and smoky vapours together with a small portion of the spirits, by the venall artery. In the *Dyaftole* the ends of the heart are corrugated and contracted, the Basis being drawne to the *Macro* or poynt, and the poynt to the Basis: so that the heart becommeth shorter in his longitude, but is so amplified to his sides, that his figure commeth neere to the spherical, which is the figure of most capacity. Contrariwise, in the *Systole* the ends of the heart are distended, but the sides fall and flag, as it were, and so the heart becommeth longer, but narrower.

The vse of the fibres of the heart.

Both these motions are performed by the helpe of the fibres, for the right which passe directly from the Basis to the poynte, contracting themselues make the dilatation. The transuerse or circular straightning the sides, doe make the contraction; the oblique serue for retention, and make that double rest whereof we spake. Againe, in the *Dyaftole* all the values are extended, in which distention, the forked values make many chinkes or crannies as it were, but the *semi-lunary* valves do close vp the ends of their vessels. In the *Systole* all these membranes are contracted, and then the forked shutte those chinks and crannies which they made when they were dilated, and the *Semi-lunary* being corrugated or wrinkled, leaue such distances or rifts by which the blood freely passeth forth. Moreover, the dilatation of the heart is before the contraction in time, for ayre is first drawn in before the smoky excrement is shut out: and againe, inspiration must needs be first, because expiration is last, for the life vanisheth in expiration.

Greater vse of expiration then of inspiration.

But whether is of greater necessity? We answer, that in hayle bodies they are of a like necessity. In Agues especially rotten and putrid there is more necessity of expiration, as wee see in those that dye, their *Systole* and expiration is greater, because Nature is more diligent to exclude that which is hurtfull, then to draw that which is profitable; now we know that the ayre that is drawne is familiar to the heart, but the smoaky and sooty excrement is an offence vnto it.

whether the heart striketh the brest in the *Dyaftole* or in the *Systole*. Galens authority.

Lastly, it is questioned whether it strike the brest (which wee feele with our hand about the left brest) in the dilatation or in the contraction. Galen seemeth to differ herein from himselfe: for in one place he saith, *Quando rursus euacuatum fuerit Cor, & in Naturalem figuram reuerterit, tunc proficit pectori, & percussione facit, & ita concidens pulsus per facit*: that is, Againe when the heart is emptied, and returneth to his Naturall figure and position, then it leapeth against the brest, and maketh that percussio, and so falling accomplisheth that pulse.

Reasons to the authority.

To this authority may be added this reason: when the heart is dilated it becommeth short, and againe long when it is contracted. Wherefore when it is distended it goeth from the brest, and when it is contracted it flyeth to the brest, and so striketh it; beside, almost all Anatomists say, that the flesh of the heart is more solid in the *macro* or point, then in the Basis; least that in the violent motions of the brest when it toucheth the bone, to which it is very neere, it should be hurt, and so vitiate his motion; the point therefore striketh the brest, but experience and waighr of reason is on the contrary part.

The consent of Anatomists.

What the truth is.

The reasons to proue it.

The reasons are these: If you lay one hand vpon the brest, and another vpon the wrest, you shall perceiue in either place at the same time the same stroke; and this both Galen hath obserued in the 3. chap. of his 3. Booke *de prasag. ex-puls.* and we daily proue it true by dissections of liuing creatures; but it is most certaine, that the stroke of the artery is in the end of the dilatation

tion, for the end of the contraction cannot be left; therefore that stroke of the heart we feele, is the end of the dilatation, not of the contraction.

It may be obiectioned, that when the arteries are distended, the heart is contracted, and when the heart is contracted, then are the arteries dilated; if therefore you place your hand vpon the wrest or the temples, and there finde the stroke of the artery, and with the other hand vpon the brest finde also the stroke there at the same time, it must follow necessarily, that the hart is then contracted when the arteries are dilated, but the vanity of this obiection shall appeare in the next exercise. For the heart and the arteries are distended at the same time and in the same motion.

Obiection.

Answer with reference.

Moreover, if the heart when it is contracted should strike the breast with his mucro or point, the stroke should not be felt at the left breast but somewhat lower, for the point of the heart reacheth to that place of the chest into which the midriffe is inserted. The breast therefore is beaten not with the point of the heart, but with the left ventricle when it is distended, which is the originall of the arteries; for when the point is gathered to the Basis in the *Diastole*, the heart is made larger, and so striketh the breast at the left Pap; but when it is contracted, the heart becommeth longer and narrower, and so falleth back into the chest, and of this also is *Galens* opinion in his Anatomicall administrations, and in those golden Hymnes of his, of the vse of the parts. Let vs proceed to the other difficulties which concerne the motion of this heart and arteries.

QUEST. IV.

By or from what power the Arteries are moued.

The motion of the Arteries *Hippocrates* first of all others called *σφυγμὸν*, that is, the Pulse, and although hee left indistinct precepts about it, yet was it not vterly vknowne vnto him, as some nouices would beare the world in hand, which may be prooued by many places, if it were necessary to wrastle in that floore: but wee list not insist in that, but proceed. That the forme of the motion of this pulse is all one with that of the heart, for it consisteth of a *Diastole* and a *Systole*, and a double rest.

Hippocrates first found the pulse and so named it.

The forme of the motion.

In the *Diastole* the Arteries draw and are filled, and in the *Systole* they expell. The rest is double, vnlesse Nature be prouoked eyther by a violent obiection, or by some externall cause; for then the arteries may be moued together with an insensible rest, as in the pulse called *Di-crotus* and *vibrans*: so a stone which is throwne vpwrd, if it meet with a falling Tower, descends againe without any rest, although *Aristotle* thinketh that no violence can tie to contrary motions without some rest.

Aristotle.

The vse of this pulsation is double; one greater, another lesser. The greater is for the conseruation of the naturall heate as well of the heart as of other parts: for by contractions whatsoever is smoky the arteries auoyde, and so the naturall heate is kept from suffocation, by dilatation they draw outward ayre into the body, by which the dissolusion of the same heate is inhibited.

The vse of pulsation double.

The lesse vse is, that in the braine may be ingendered the animall spirit, for by the pulsation the spirits of life are carried into the *plexus choroides*. There is therefore the same vse of the pulse that there is of respiration, sauing that what respiration doth to the heart, that the pulse of the arteries doth to other parts, which as they neede lesse heate then the heart, so are they not so soone offended: for if the heart be deprived of respiration, presently the creature perisheth, but the part dyeth not as soone as it wanteth the pulse.

The nature of the motion of these arteries is very obscure, and many things must be resolved of and knowne, before we can attaine to the vnderstanding of so deepe a mystery. First of all, whence are the arteries moued, from themselues or from some other? *Protagoras* thought the arteries did moue of their own accord, and that they had the same pulsative vertue that the heart hath in themselues, not by influence. But this *Galen* disproueth by an obseruation; for saith he, if an artery be cut ouerthwart, that part onely will pulse which remaineth ioyned to the heart; but that which is separated from the heart, will not beate at all.

The nature of their motion obscure. *Protagoras*.

Galen in stance.

Erasistratus was of minde, that the arteries were not moued by any proper power of their owne, but by the constraint of the heart, and that constraint he meaneth not of any faculty but onely of some matter. *Aristotle* thought they moued, because of the feruour or boyling of the blood

Erasistratus.

Aristotle. The reasons.

Neither heat,
nor spirits, nor
blood, are the
immediate
causes.
Not heat.

blood contained in them, whom some haue followed, because they know that the spirits are those which make strife and offer violence; and again, because the veines neere the heart doe not moue, which they would do (say they) if they had in them such blood as the arteries haue: but wee will proue that neither heat nor spirit, nor boiling blood can bee the immediate cause of this perpetuall motion. For the heate, it either hath a body or hath no body; if it had a body, then the arteries that are neerer to the heart would sooneft be dilated; if it be onely a naked quality, then will it first heate those things that are neere hand, and after that which is farther off. For heate is not of the number of those formes which may in a moment be diffused as light, but his contrary is cold, which first must be expelled out of the subiect before it selfe be receiued: but the pulse is in a moment diffused through all the arteries, it is not therefore onely from heate.

Not blood.

It is not of spumous blood; for then it would follow that where the blood is more plentiful and hotter, there the pulse should be not onely more vehement, but more frequent also; and so the pulses of the great arteries should be quicker then the pulses of the small: but experience teacheth, that all the arteries both great and small doe moue alike vnlesse there be some hinderance; they are not therefore moued by the blood contained in them. Furthermore, intercept an artery with a tye, and the part below the tye, though it strut with spirits and thin blood, yet will not beate, because the continuity of the faculty with the heart is intercepted; but as soon as the tye is vnloosed, the artery will instantly beate againe, but neither the heate nor the humor can in a moment or instant flow from the heart into the vter arteries. Adde to this, that if the arteries should beate because of the blood contained in them, then in all large pulses there should also be vehemency, which is nothing so: For saith *Galen* in his Booke *de usu pulsuum*, and in the fourth *de causis pulsuum*, there is a pulse which is small yet vehement, and there is likewise a pulse which is great but languid and faint, which variety cannot come from the heart.

An instance.

There may bee
great, yet a
faint pulse.

Asclepiades his
opinion.

Asclepiades acknowledgeth a faculty in the motion of the arteries; but whereas this motion is in dilatation and contraction, he affirmeth that the distention onely is from the faculty, and the contraction from Nature; that is, from the predominant Element and from the waight, because when the creature is dead the arteries doe fall. So bladders if they bee filled with any thing they are distended, but they fall of themselves: and all round and hollow bodies are dilated by some faculty, but afterward doe fall with the waight of their owne parts. On the contrary, those things that are contracted by any faculty, that faculty ceasing, they are againe dilated. Therefore if the arteries bee dilated by a faculty, then are they contracted by their grauity, and so on the contrary: wherefore they need not a facultie for both.

Herophilus his
opinion.

Herophilus quite contrary will haue the contraction to be performed by a faculty, but the dilatation (saith he) is nothing else but the returne of the artery to his natural position: Because (saith he) the arteries of dead carcasses being cast into hot water, when they haue gotten the measure of heate that they had in the liuing body, will be dilated, but neuer fall, because there wanteth a faculty: but they are both deceived.

How both
were deceived.

For if both the *Diastole* and *Systole* came not from the faculty, but from the constitution of the artery, then the artery should euer keepe the same magnitude, and the same vehemency of pulsation; but we see that the pulse is now greater, now lesser, as the strength is great or little; sometimes the *Systole*, sometimes the *Diastole* is greater, as the vse of either is increased. There want not some who strive to proue that the motion of the arteries is from the braine, standing vpon one authority of *Galen*, where he saith in the 2. Book *de causis pulsuum*, When in a man the pulse beginnes to be convulsive, presently he is taken with a convulsion, which seemeth to intimate, that there is one original of the faculty of pulsation, and of that to which convulsion doeth belong. But *Galen*s owne obseruation bewrayeth the vanity of this opinion. For if the braine be compressed, sence and motion will perish, but the arteries will stil beate. If the nerue which commeth from the braine to the heart be cut or intercepted, the creature becommeth dumbe, but the arteries beate still.

That the mo-
tion of the ar-
teries is not
from the
braine.

The true cause
whereby the
motion is mo-
ued.

Seeing therefore that the arteries neither moue by a power of their owne, nor from the Elementary forme, nor onely from heate, nor from a spirit or spumy blood, it remaineth necessary that they should be moued by a pulsatiue power of the heart. For if they should be moued by any thing saue by a faculty, their motion should be not continuall but violent: neither would there be any attraction of ayre in dilatation, but the boyling blood would take vp all the roome.

This

This Faculty or power pulsatiue is in a moment carried, not through the Cautie but along the coats of the Arteries; and that it is carried in a moment this is an argument that all the Arteries are mooued with the same motion, all together in the same time when the heart is mooued. If it be obiected, that *Galen* (in the 1. *de different. pulsuum*, and 2. *de prima cognitione ex puls.* speaking of those that haue hot hearts, and cold Arteries, in whom the parts of the Arteries that are neerer to the heart are dilated sooner then those that are more remote) is constrained to confesse, that the pulsatiue power is mooued through the artery and slowly by degrees. I answer, that the faculty floweth in a moment vnlesse it be hindred. But it may bee hindred sometimes by his owne fault, sometimes by the fault of the Instrument; by his owne when the heart is weake, by the Instrument when the Arteries are either cold or soft or obstructed. It remaineth therefore, that when all things are aright disposed it floweth in an instant, and not through the Cavity, but along the coats of the Arteries. *Galen* in the last Chapter of the Booke *Quod sanguis Arterijs detineatur*, giueth an instance from experience. If you put a Quill or Reede into the Arteries, which will fill the whole cavity, yet will the Artery beate; but if his coats be pressed with a Tie, it will cease instantly. If it bee obiected that the Arteries in an Infant beate before the heart, and therefore the pulse is from the spirit, not from the heart: I answer, that the Infants Arteries do mooue by a vertue that proceedeth from the heart of the Mother: for the Arteries of the Infant are continuall with those of the Mother, and receiue as well life and the pulsatiue Faculty from her, as the Liuer and all the other parts do nourishment.

Which way the Faculty is led.

What may hinder the motion of the heart.

An instance for experience.

Obiection. Solution.

QVST. V.

Whether the Arteries are dilated, when the heart is dilated, or on the contrary then contracted.

Here ariseth now a more obscure, thornie, and scrupulous question, then the former, and that is, whether the Arteries and the heart are mooued with the same motion. For the explication whereof, we must first resolue that the Arteries are filled when they are dilated, and emptied when they are contracted, that they draw when they are dilated, and expell when they are constringed. The reason is manifest; For the vessels must needs draw with that motion whereby they are made most fit to receiue; but the vessels by how much they are more enlarged by so much are they more capeable: now they are enlarged by dilatation; therefore, when they are dilated they draw and are filled: so that *Archigines* is no way to be harkned vnto, who was of opinion that in the *Systole* the arteries doe draw and are filled, and in the *Diastole* do expell and are emptied; whose argument for this was, because in inspiration the lippes are streightned, and the Nostrils contracted: but whether this *Diastole* of the Arteries bee at once and together with the dilatation of the heart, that is indeed a great controuersie. *Erasistratus* was the first that thought their motions contrary, that is, that when the heart is dilated, the Arteries are contracted; and when the heart is contracted, the Arteries are dilated.

Adifficile question.

The Arteries are filled in their dilatation.

Archigines

The first opinion. Erasistratus.

Authorities

Reasons. The first.

Amongst the new writers, these haue sided with him: *Fernelius*, *Columbus*, *Cardane*, and *Scaliger*: and truely his opinion may be confirmed by authorities and reasons. *Galen* in his Booke *De Puls. ad Tyrones* saith, that the Vitall Faculty doth mooue diuers bodies at the same time with diuers motions, which can bee vnderstood of nothing else but the motions of the heart and of the arteries. *Auicenna* *Fen. 1. cap. 4. doctrin. 6.* affirmeth, that the vitall Faculty doth together dilate and constringe. The reasons beside these authorities are: In the *Diastole* the heart draweth blood by the hollow veine into the right Ventricle, and aer by the venall artery into the left. Therefore at that time the heart is filled, and the vessels are emptied. Contrariwise, in the *Systole* the heart expelleth the Vitall spirit into the arteries; therefore at that time the heart is emptied and the arteries are filled; but when the arteries are filled they are distended, and when they are emptied they fall: wherefore when the heart is distended, the arteries are contracted, and when it is contracted they are distended. Beside, there is the same proportion betweene the arteries and the heart, which there is betweene the heart and the deafe eare: but it is most certaine, which our eie-sight reacheth vs, that the motion of the heart, and of the eares of the heart are diuers; for when the heart is dilated, then those eares doe fall; and when the heart is contracted, then they are distended and filled: wherefore the heart and the arteries are mooued with a diuers motion.

The second.

Na

Thirdly,

The third.

Thirdly, as attractions and expulsions are in other parts, so it is likely they are in the heart; but when the stomach driueth out the Chylus, the mesentery veines do draw it, and therefore when the heart driueth out bloud and the vitall spirit, then the arteries draw it; and so their motions are contrary.

The fourth.

Fourthly, when the heart is dilated then becommeth it shorter, and draweth vnto it selfe the arteries that are continuall with it and therefore maketh them narrower, but when the heart is contracted the arteries are dilated and become longer.

The fifth.

Lastly, if one hand be placed vpon the brest and another vpon the wrist, the same stroke will at the same time be perceiued; but the stroke and percussio of the brest is done by the contraction of the heart, for when it is contracted it commeth to the brest and striketh it: but when it is distended it becommeth shorter and recedeth from the Chest. Now the stroke of the Artery is not from the contraction, but from the dilatation. Wherefore the heart and the Arteries are moued with a diuers motion. But not withstanding all these reasons, yet are we perswaded with *Galen* in his booke *de vsu puls.* and *3. de presag. expuls.* and *6. de vsu partium*, that the heart and the Arteries are moued with the same motion. And this we are taught first by experience, then by strong and inuincible force of argument. The

The truth it
selfe proued
by

Experience.

experience is instanced by *Galen*, which every man may make tryall of in himselfe. If one hand be laide vpon the brest and another vpon the wrist, the same stroke will bee perceiued at the same time; and besides in dissections of liuing creatures wee haue often obserued the very same. But beside, these reasons doe euince it. We haue already proued that the arteries are not moued by the impulsio of the blood, nor by the boyling or heate of it, but by a faculty and that not of the Arteries but yssuing from the heart; therefore they are contracted by the faculty which contracteth the heart, and distended by the same force and power by which it is distended. But if they were moued with diuers motions, it would follow that the dilating faculty must flow from the heart in the same moment wherein it is contracted, which no Philosopher will dare to admit. Beside, that motion is the same which hath the same efficient and finall causes: but the pulsatiue power is the same which moueth the heart and the Arteries; and the end also is the same, to wit, nutrition, temperation or qualification, and expurgation.

Reason.
First.

Second.

Third.

An instance.

Thirdly, the motion of the part and of the whole is all one; and a part of that beeing moued which is continuall with the whole, the whole is moued: as is seene in the strings of Instruments: but the Arteries and heart are continuall together; wherefore if they be moued by the heart as is most euident, then will it follow necessarily that they shall both bee moued together by the same motion.

Fourth.

Fourthly, vnlesse the heart and the Arteries were together distended and together contracted, the heart should not bee refrigerated in his dilatations, because the Arteries being contracted there would follow an exclusion of the smoky excrements into the left ventricle, and so the heart and the artery should mutually strue, and their motion be in vaine.

Fifth.

Fifthly, it would follow that in the contraction the heart should draw ayre from the dilated and distended arteries. For sometimes the vse of respiration being taken away, as in passions of the mother, the heart doth not draw ayre from the Lungs and the venall artery, because then no ayre is drawne in by the mouth and the nostrils, yet the heart moueth and the arteries beate. Now it moued for the generation of vitall spirits, but this generation is not without the admision of ayre: it draweth therefore ayre from the arteries not contracted because then are the excrements expelled, but from the arteries distended. But if when the arteries are distended the heart be contracted, then the contracted heart shall draw from the distended arteries, and so shall the motions of the heart become contrary.

Sixth.

Sixthly, this faculty is incorporeall, communicating it selfe in a moment: wherefore at what time the heart beginneth to dilate, it distendeth all the arteries, and so on the contrary.

Seventh.

Finally, the pulses which are in anger, sorrow and other passions doe sufficiently shew that the heart and arteries are moued with the same motion. For, if when the heart is dilated the arteries should bee contracted, then in anger the pulses should bee small, in griefe great; because in anger the heart is somewhat contracted and therefore the arteries should bee but a little dilated. Contrariwise, in griefe the arteries should bee very much dilated because the heart is strongly contracted: but how false this is, common experience will witness. Let vs therefore settle our selues in *Galen*'s opinion and determine, That the arteries are dilated and contracted when the heart is dilated and contracted.

What decei-
ued the for-
mer learned
men.

The structure of the vesselles of the heart, deceiued those learned men which hold the

con.

contrary opinion, together with the obscure maner of the hearts motion. For there being in the Basis of the heart foure notable vessels: the hollow veine, the arteriall veine, the venall artery, and the great artery: they imagined that the heart in his *Dyaſtole* did draw something from those foure vessels, and in his *Systole* drive something into them all; and that therefore in the *Dyaſtole* of the heart they were all emptied that the heart might bee filled, and in the *Systole* of the heart they were all filled because the heart is emptied.

Beside, they seeme to haue beene ignorant of the efficient cause of the motion of the heart and the arteries. For they would haue the heart and the arteries to be dilated, because they are filled with ayre or blood. But the truth is, that the arteries are not dilated because they are filled, but because they are dilated therefore are they filled: onely the power and pulsative faculty which floweth from the heart distendeth the arteries, not the blood contained in them. For whether they be distended or contracted they remayne alwayes full of blood: but if you shall thinke that they are distended because they are filled, then will it follow that at the same time they cannot bee all distended; for how can that corporeall blood bee carried in a moment from the heart to the arteries of the foote? I will giue you for illustration of this matter an elegant example. The smithes bellows because they are dilated are therefore filled with ayre; and the chest because it is distended by the animall faculty is presently filled; but purses, bagges and the hogges bladder, with which boyes often play themselues, are distended because they are filled.

But wee must carefully marke, that whereas there are foure vessels of the heart, onely the arteries are filled because they are dilated: the other three are distended because they are filled, and doe fall because they are emptied; because onely the arteries haue the motion of *Systole* and *Dyaſtole* from the faculty of the heart, the other vessels are immonable. And this is the reason why when the heart is contracted, the left eare is dilated, because the eare is a kinde of store-house of ayre and blood which suddenly rush into it; from the which when the heart draweth blood or ayre, it is of necessity that it should contract it selfe.

These things being determined, it will bee easie to make satisfaction to whatsoever is objected on the contrary part. The authorities of *Galen* and *Auicenna* are not contrary to our determination, for they call the heart and the arteries diuers moouable bodies, which at the same time are mooued with diuers motions; for they are dilated and contracted at once and together by the same vitall faculty. And I imagine that *Galen* and *Auicenna* spake this against the ancients, who sayde that onely the dilatation was from the faculty, but the contraction from the Elementary forme and from the waight of their bodies. The reasons are thus to bee answered. The arteries are not distended because they are filled but are filled because they are distended; neither doe the arteries fall altogether when they are contracted but reayne still their cavity; and the plenty of the matter is more which issueth from them, then that which is receiued into them: the arteries therefore are not dilated by the influence of the matter which goeth out of the heart.

The second argument is of no moment: for there is not the same reason of the heart and the eares thereof; for the eares expell nothing, but the arteries expell more at that time then they receiue; beside, the eares are dilated because they are filled, but the heart and arteries are therefore filled because they are dilated: and this did *Hippocrates* silently innuuate where he sayth, The heart is mooued by his whole Nature; that is, by his proper faculty: but the eares doe priuately swell and fall againe; that is, as they are filled or emptied of ayre and blood.

To the third reason we thus make satisfaction; in other parts the attractive and expelling vertues are in-bred, but contraction and dilatation the arteries haue by influence.

The fourth reason instanceth but in a light contraction, which is into length not into breadth.

Last of all, the last reason is against experience, for wee haue before proued that the breast is beaten in the dilatation, the left ventricle being largely displayed.

What the truth is.

The arteries in both motions are still full of blood.

A fit example.

The former distinction concerneth onely the arteries.

Why the left eare is dilated when the hart is contracted.

QUEST. VI.

Of the generation of vitall spirit, and by what wayes the bloud goeth out of the right into the left ventricule of the heart.

Of the vitall spirits.

WEE haue hitherto proued that the motion of the heart and the Arteries is one and that a perpetuall motion, consisting of a *Systole* a *Diastole* and double rest, arising from a naturall pulsatiue faculty of the Soule residing in the heart, there assisted by the structure of the fibres and thence deduced by influence or irradiation into all the arteries at one instant, not through the cavity but along their coates. Now because all this curious and maister-peece is wrought by Nature, onely for the generation of vitall spirits, it is more then requisite that we vnderstand what this spirit is, and how generated. We will not trouble you with many things hereabout, but those we will insist vpon shall not bee triuiall and ordinary, but hewne out of the deepe quarries, vnueyled from amongst the most secret mysteries of Nature. That there is a vitall spirit in perfect creatures no man euer denied. *Hippocrates* in his Booke *de Generat.* and *de principiis* first put vs in minde of it, *Galen* hath a thousand times inculcated the same.

All physicians agree that there is a vitall spirit.

The prince of the Arabian tribe *Auicenna* hath set his seale vnto it; and all the multitude of Greeke and Arabian Physicians haue added their suffrages. And amongst the later writers, though some haue doubted concerning the Naturall and the Animall spirits, yet all with a ioynt consent allow of the vitall. There is therefore a vitall spirit which is primarily seated in the Left caue or denne of the heart as it were in a shoppe or work-house; and from hence it is diffused by the arteries as by conduits or pipes into the whole body. This spirit cherisheth the in-bred heat of every part, quickens it when it becommeth drowsie, bringeth it forth when it lyes hid, and being spent or wasted restoreth it againe.

The office of this spirit.

This spirit whilest it shineth in his brightnes and spreadeth it selfe through all the Theater of the body, as the Sunne ouer the earth, it blesteth all partes with ioy and iolitic and dies them with a Rosie colour; but on the contrary when it is retracted, intercepted or extinguished, all things become horrid wanne and pale, and finally doe vtterly perish. So wonderful and almost so heavenly are the powers of the heat and spirit, that the diuine *Seneca* applying himselfe to the rude capacity of the people (as *Galen* witnesseth, hee sticketh not often to doe) calleth it the Soule, that is, the chiefe instrument of the Soule.

Hippocrates, called the spirit the soule.

The Soule of a man (saith he) is seated in the left ventricule and is nourished not by meates or drinkes from the lower belly, but by a most pure and bright substance out of the separation of the bloud; as if hee should say, it is creamed as it were off from the bloud, and by the heat of the heart rarified into an aethereal consistence. For the Soule it selfe being a denison of heauen (*τὸ γὰρ καὶ γένος ἑσπερίον*, for wee are also of his generation) how could it be tyed to this house of clay vnlesse it were by the mediation of some middle Nature, participating (as neere as mortality will suffer) of the purity of the Soule and yet hauing his originall from the body, that the Soule might haue a nimble and agile instrument to follow her sudden designs.

Paul. The spirit is the medium betweene the soule and the body.

By the Soule therefore in this place, *Hippocrates* meaneth the vitall spirit, which is nourished with pure and attenuated bloud, that is, restored; for therein lyeth a mystery: that the nourishment of the spirit is not, in all things, like the nourishment of the parts, but rather is an illumination, vnition and establishment of them, as we shall heare afterward.

The vses of the vitall spirit within & without the heart.

The vses of this vitall spirit are according to his nature diuine also, both within and without the heart. In the heart to be the principall instrument of the functions of the heart; without the heart his vse is double: one to bee the subiect of the heat of the heart which wee call *Calor influens* the influent heate, which it may receiue as the ayre doeth the light and so exhibite it to the whole body; and the other to bee the matter of the Animall spirit.

His matter double.

This vitall spirit hath a double matter aery and sanguine, for it is made (as *Galen* saith in his seventh Booke *de placitis Hipp. & Platonis*) of aer and bloud mingled together. That it is made of aer *Hippocrates* taught in *Epidemiis* when he saith; Such as is the aer such are the spirits; a foggie and cloudy aer engendreth a grosse and dusky spirit: and againe *Hippocrates*; The South winds dull the hearing, they are misty and breed a dissolution of the spirits. this

Ayre.

Their aery substance alone cannot contain within the body the vitall heat; It is necessary therefore that there should be an admision of thin and subtile blood which should restrain the impetuous force of the ayre. And both these matters before they come vnto the left ventricle of the heart stand in neede of preparation. The ayre drawne in by the mouth and the nose is prepared in the Lungs his vessels and his whole soft rare and spongie substance; and by a long delay doth acquire a qualitie familiar to the in-bred spirite. This aire thus prepared, is conueyed by the venall Artery into the left ventricle. And this is the preparation of the ayre, these the passages by which it is conducted to the heart.

Concerning the preparation of the blood, in what place it is made and accomplished and by what waies it is deriued into the left Ventricle, the Anatomists do strue with implacable contention. I haue read and turned ouer many of the Monuments both of the Ancients and also of later Writers, and I finde foure opinions euerie one repugnant to another.

The first and the ancient is that of *Galen*. Hee thinketh, that the blood is carried through the Hollow veine which with an open mouth gapeth into the right ventricle of the Heart as into a Cisterne, and is there boyled attenuated and subacted, and then a part of it is sent by the arteriall veine into the Lungs and distributed into them for their nourishment, the remainder is carryed through the middle partition, which like a wall seuereth the two Ventricles asunder, into the left, where it is by the in-bred vertue of the heart mingled with the ayre and doth there acquire the forme of a vitall spirit, assisted partlie by the in bred spirit of the heart, partly by an exceeding heate and flame whereby it is wrought as in a Furnace into a more pure Elementary forme. This opinion of *Galen* which of all the rest is most true, some of later times haue condemned. For they do not thinke it possible that in so short a time so great a quantity of blood as is sufficient for the generation of vitall spirits for the vse of the whole body can sweate thorough the wall of the heart into the left ventricle, there being no apparant and sensible passages, and the wall also being very thicke and solid.

Morcouer they obiekt, that if it should bee so, then the labour of the heart were vaine and idle; for why should not the blood and ayre being thus attenuated repasse againe out of the left into the right, seeing the same way is open for them, the same passages and no valves or gates to hinder it? But these Obiections are of lesse weight then that they should weaken the authority of so great an author of our Art and *Galen* himselfe foresaw (in the 15. Chap. of his 3. Booke *De Facultatibus Naturalibus*) that there would bee some which would make their childish Obiections. Wherefore in another place hee thus elegantly explaineth himselfe. Out of the right Ventricle that which is the thinnest is drawne through the pores or passages of the partition, whose vtmost ends can hardly bee perceyued, because after death all such yea all other passages that are not distended by the matter contained in them, doe fall together. But that it is this way transmitted hence it is manifest, because Nature neuer endeouureth any thing rashly or in vaine; but there are certaine dens in the fence or partition, deep bosomes very many which grow narrow to their outlet, by which the blood may freely and with a large streame yssue out of one ventricle into another. But the cause why this blood doth not returne againe out of the left into the right side, may bee well referred to the peculiar force and vertue of the heart.

The left Ventricle drawes this blood and retaineth it by an in-bred propriety and for a while enjoyeth it, and then thrusteth it forth into the Tunnels of the arteries. So the blood which either hath sweate through the coates of the veines, or is powred forth at their mouths into the substance of each part, returneth not into the veines againe because it is reteyned and receyued into the substance of the part. The truth of this opinion, albeit it be most cleare of it selfe, yet it will be better manifested vnto vs after we haue taken knowledge of other mens conceites and discussed them to the full.

The second opinion therefore is that of *Columbus*. That the blood indeed is attenuated and prepared in the right Ventricle of the heart, but is carried into the left Ventricle by other passages and not through the pores of the Fence or partition. And what neede wee seeke for so smal and secret pores, when it hath an open channell, the arteriall veine, which (saith hee) carrieth all the blood out of the right ventricle into the Lungs, where a part of it is distributed for their nourishment, the rest is returned into the venall artery and from it together with the ayre into the left ventricle; and this opinion of his he strengthneth with two reasons. The arteriall veine (saith he) is greater then was necessary for the nourishment

Bloud.

How & what the aery is prepared.

How the Bloud is prepared.

4. Opinions.

The first and trust of *Gale*.

Obiections.

Galen himselfe explained by himselfe.

The second opinion of *Columbus*.

ment of the Lungs, it is therefore like that it was destinated also for the conueiance of the blond of the generation of the vitall spirits. His other reason is this : there is alwayes in the venall artery thinn and arteriall blood ; this blood is receiued not from the left ventricle, for the three-forked Membranes will not suffer it; therefore frō the veine of the Lungs.

The answer
to Columbus
his
First reason.

These things are very probable and clogged with the veile of truth, yet not to bee admitted for currant. For whereas he saith the veine of the Lungs is larger then their small body stands in neede of, we vtterly deny it. For the rare lax and spongy substance of the Lungs is easily dissipated, it is also continually moued, and by reason of the neighbourhood of the heart is easily inflamed ; whence comes a huge expence of the threefold nourishment ; but where there are great goings out, there also had need be great commings in : now the blood could not come plentifully in but by a wide vessell, therefore the vessell of the Lungs was of necessity very ample and large. Besides saith *Galen*, Nature made this vessell large, that how much was abated in the nourishment of the Lungs by the vessells thicknesse, so much might be recompenced in his amplitude and largenes.

Lib. 6. de usu
part. cap. 10.

To the second.

To the second reason we may answer thus : The blood that is found in the venall artery is a portion of the vitall spirits and arteriall blood which the heart poured forth into the substance of the Lungs : for all life being from the heart and the vitall spirit, and no deriuations of vessells from the great arterie vnto the Lungs ; it is likely yea necessary that vitall spirits should bee conueyed to the Lungs by the venall artery, neither is there any reason they should object the opposition of the three-forked Membranes; for there are but two in the orifice of this vessell, because it behooueth not that it should bee perfectly closed vp. Happly they may object the contrary motions and the mixture of smoky vapor with the spirits, but they attribute very little to the wonderfull prouidence of Nature and are ignorant what the diuers appetites and attractions of particular parts can do. The veins of the mesentery do together and at once distribute Chylus and blood : Milke passeth sometimes out of the brest all along the trunke of the hollow veine, yet is not mingled with the blood, but passeth out by vrine pure and sincere ; and as we shall by and by proue, the matter and quittance of those wee call *Empyici* is purged by the left ventricle of the heart and so through the arteries into the kidnies and the bladder, yet is not the vitall spirit stained with this filthinesse if all things be in good order with the patient : and so much for *Columbus*.

An objection.
Answer.

Pure milke a-
noyed by
vrine.

The third o-
pinion of *Bo-*
tallus.

The third opinion is that of *Iohn Botallus*, the french Kings Physition, who boasteth that he found a passage open which no man euer knew, out of the right deafe eare into the left, by which hee imagineth that the blood prepared in the right ventricle passeth into the left. This he saith is very euident in Calues and other young creatures, but in men and creatures that are growne, it is not so open.

Confuted.

This opinion of *Botallus* hauing no reasons to establish it, ouerthroweth it selfe ; for if Nature made this passage for this vse, to transfuse the blood from the right ventricle vnto the left ; then should it bee manifest in all creatures in all times of their life, yea the creature growing large and the naturall heat daily increasing, the passage also should grow more manifest as whereof there is euery day greater vse. But *Botallus* confesseth it is not found in Oxen nor creatures of any growth.

Beside, this passage is in the orifice of the hollow veine, how therefore should the attenuated blood flow backe from the right ventricle vnto the veine, seeing there are three valves open without and shut within, which doe admit the blood indeed into the right ventricle but will not suffer it to flow backe into the hollow veine ? This good honest man was ignorant of the vse of his passage, which *Galen* accurately describeth first of all men in his golden bookes of the vse of the parts.

Botallus igno-
rant of the
vse of the
passage he
thinks hee
found.

My selfe haue seene this passage very often with the other arteriall pipe, but they serue onely for the Infant before it bee borne, because his life and nourishment is much vnlike to that it is afterwards, and therefore after the birth the passage is altogether shut ; and the pipe so dried vp that a man would deny that euer any such thing was ; the vse of this passage & pipe wee haue at large described above, and thither doe wee transmit the Reader that is not satisfied concerning them.

The fourth
opinion of
Vlmus.

The last opinion of the preparation of the blood, is that of *Vlmus* a Physition of Poyton, who set out a very elegant booke of the spleene. He is of opinion that the arteriall blood is concocted, attenuated and prepared in the spleene, and thence conueied into the great artery and so to the left ventricle of the heart, where, by an admirable and mysticall worke of Nature it is mixed with the ayre already prepared by the Lungs. I must needs confesse

that

that the opinion of *Plinius* pleased me wondrous well, both for the nouelty of the conceite, as for that he handled the matter with great subtilty of argument, and deepe discourse; but because he leaneth vpon vnfound foundations to establish a newe doctrine, which doe shadow the brightnes of the Art of Anatomy, it will not be amisse to recal the principal points of it to the touch-stone in this place.

A subtile disputation.

First of all, hee thinketh that the blood cannot passe out of the right ventricle into the left by the fence or partition, because (saith he) if this way were not sufficient in a tender Infant in whome the vessels are more laxe and the substance of the wall more rare and thinne, and wherein there is lesse dissipation or waste of spirit; then surely it will much lesse suffice in an older man: but this way is not sufficient in the Infant, so that nature provided another; to wit, two arteries, which are carried from the Navel to his crural arteries. Therefore in a growne man it is necessary there should be other more open passages.

An argument truly most subtile, but most false and stuffed with error: For in the Infant, the blood doth not sweate through from the right ventricle to the left, because there is no generation of vitall spirits in the ventricles of the heart; but the Infant draweth the mothers spirite by the vmbilicall arteries, which is diffused into all the streames of the great artery. The Lungs are not nourished with pure and thinne blood but with thicke, carried vnto them by the hollow veine; wherefore from that hollow veine to the venall arterie there is a cleare passage, and a conspicuous pipe from the great artery to the arteriall veine, by whose interposition the vessels of the heart in the Infant are vnited.

Answer to Plinius.

The opinion therefore of *Plinius* is false, because in the Infant there is no shop of the spirits, neither doth the orifice of the hollow veine powre out blood into the right ventricle of the heart; for that, as *Galen* sayth in the 15. Chapter of his 6. Booke, *de vsu partium*, the Lungs in an Infant are redde, dense and immouable, and are nourished with thicke and grosse blood.

Secondly, the membranes placed in the orifice of the great artery (which hee calleth not well *three-forked*, for the valves of the hollow veine and the venall artery onely are three forked, the rest are *semicircular*) he doth not imagine are made to that end that they should prohibit blood for going out of the great artery into the heart; because while the Infant was in the wombe, they hindred not the arteriall blood from entring into the left ventricle of the heart. But here *Plinius* offendeth at the stone at which he stumbled before, for nothing floweth into the ventricles of the Infants heart by his foure orifices. Not blood by the hollow veine, for what neede is there of his attenuation, when the Infants Lungs are nourished with thicke blood? Not ayre by the venall artery, for the Infant breatheth not in the womb. Not arteriall blood by the *Aorta* or great artery, for this labor were vaine, because in a moment it should bee thrust backe into the same *Aorta* againe: adde to this that there should haue beene no neede of that arteriall canale or pipe going from the great artery to the arteriall veine, vnkowne to thee *Plinius* as I see, and almost to all Anatomists.

Nothing goeth into the Infants heart out of any of the vessels.

Thirdly, whilest *Plinius* assenteth to *Botallus*, and fashioeneth to himselfe a peculiar vse of that hole or passage, he walloweth in the same puddle with him and deserueth the same reproofe *Botallus* had. In confuting of *Columbus* he is most subtile, at length hee bringeth to the birth his witty conceite which hee trauelled with, and after many sharpe throws and pinches is deliuered of it. To wit, that in the spleene the arteriall blood is prepared, because the spleene is made as it were of a woofe and web of veines and arteries inexplicably woven together: that when it is so prepared, it is sucked away by the arteries and carried into the trunk of the great artery, and so into the left ventricle of the Heart: but there be indeed many obstacles which will hinder this ready passage if wee will but stay a while and follow the streame a little.

Plinius opinion

How it can not be true.

First of all, in the orifice of the great artery there are three membranes shut without against it, so that by them the arteriall blood cannot passe: This our very eyes teach vs, and beside our great Dictator, in his Booke *de Corde*, hath in direct wordes deliuered the same. *Plinius* I know also will deny this vse of the valves; and yet I know also hee will not say that Nature formed them in vaine. I say then, that if they doe not altogether interclude or hinder the egress and regress of the blood; yet as hee himselfe is constrained to confesse, they break and stay the abundant and violent influence of the same; which if they doe, then cannot the whole matter of the vitall spirits bee brought from the spleene by the great artery vnto the left ventricle of the heart; because seeing the generation of the spirits must bee sudden and abundant, their matter also had neede to bee ministred with a full streame

Hippo. de Cordo.

fireame, and not drop or sipe by degrees into the heart. Furthermore, in the structure of the heart this is one point of Natures excellent worke-manship, that it draweth by one vessel, and expelleth by another. It draweth blood by the Hollow-veine, the same it expelleth by the arteriall veine; it draweth ayre by the venall artery which it mingleth with the blood, & expelleth the vitall spirit into the great artery; but if by the great arterie it should draw the matter of the spirits, and almost in the same moment should expell the spirit into the same great artery againe, there would be a mixture of those iuices, & in the arteries would there also be perpetuall two contrary motions, one of the blood, ascending from the spleene to the heart, another of the arteriall blood descending from the heart to the spleene, which as wee admit may bee sometimes in criticall euacuations and in notable Maister-prises of Nature, so we deny it to be perpetuall; but the generation of spirits is perpetuall.

Obiection.

Vlinus will object, that the venall Arterie leadeth ayre vnto the heart, and shutteth also out into the Lungs smokie vapours, together with some portion of blood: but wee answer, that there is not the like reason of ayre and of blood. Aire by reason of his subtiltie and finenesse can passe through the blood and the coats, which blood cannot do.

Answer.

An argument.

Moreover, if the Arteriall blood be prepared in the Spleene, and not in the right ventricle of the heart as *Galen* thought, why doth the Hollow veine open into the heart with so wide a mouth? Was it onely for nourishment of the Lungs? No verily, for the orifice of the Hollow veine is much larger then the orifice of the arteriall veine, as *Galen* saith in his 3. Booke and 15. Chapter *De facult. Natural.* Was it for the nourishment of the heart? Nothing lesse. For the heart hath a peculiar veine, called the Crowne veine by which it is nourished; therefore that patent orifice of the Hollow veine at the right ventricle of the heart, was ordained to cast in the seede of the spirits into the womb of the heart, whence they are forced and sent out into the little world of the bodie. Finally, from hence I gather, that the Spleene was not ordained for the preparation of the Vitall spirits, because the Spleene is very subiect to obstructions, not by reason of his vessels which are very ample and large, nor by reason of his *Parenchyma* or flesh which is rare & spongie, and therefore by reason of the foeculent and muddie humour contained in it: but how shall it serue for the expurgation of the drosse of the blood and for the preparation also of the same blood? We therefore conclude, that the blood is prepared in the right Ventricle of the Heart and thence is deriued into the left by the holes and nooks of the partition wall.

why the spleene
cannot pre-
pare the blood
for the heart.

The conclu-
sion.

QUEST. VII.

Whether the Matter and Quitture of those that are called Empyici may be purged by the left Ventricle of the Heart and the Arteries, and how it is purged by the Vrines, by the Seidge and by Apostemation.

His Question hath wrung the wittes of many Schollers a long time, notwithstanding according to the meane modele of our wit, we will heere, if it may be, vntie that knot. Wee call those *Empyici* with *Hippocrates*, who haue an impostume (as wee call it) or a bladder broken in the side of the Lungs, the matter of which is powred out into the cavity of the Chest, and there is kept and floweth vp and downe, so that with the impurity of it the Lungs are as it were laid in sleepe.

Who be *Empyici*.This quitture
may bee pur-
ged 4. waies.The easiest
way.The other 3.
wayes.

By Vrines.

An instance.

This purulent matter, according to the doctrine of *Hippocrates* may be purged 4. waies; Vpward by the mouth, by the Vrines, by the Seidge and by Apostemation. The vpward excretion is by a proper motion of the Chest, casting that which is noisome with a strong contention out at the mouth. This is familiar to Nature, and the way which wee alwayes desire Nature should take, for it is by places naturally commodious, & witnesseth a strong force and power of all the Faculties. And this is the proper *Crisis* of the *Empyici*, of those that haue pleurifies and inflammations of the Lungs: and this is the best and the safest way. But if Nature be insufficient to mooue this way, either by reason of the thicknesse of the matter that yeeldeth not to the concussion of the chest, or because of the weaknesse of the Muscles: Then Nature is so wise and prouident that she openeth another passage, findeth out some other way by which she may ease her selfe both of the disease, and of the cause of it. Therefore, oftentimes she purgeth this purulent matter by the Vrines, sometimes by Apostemation, sometimes but rarely she emptieth it by the seidge.

That it passeth away by the Vrines is prooued by daily experience, and euen now whilst I am writing these things, Nature hath found this very way in an olde Gentleman a Law-
yer,

yea, who hauing had a Pleurisie, and no meanes of bloud letting or almost any other of any moment, is beholding to Nature, who daily in great and notable abundance venteth this noisome humor by the Vrine. But beside experience, it may also bee confirmed by the authority of very many as well ancient as later writers. Hippocrates and Galen are very plentifull witnesses of it: wee will onely quote the places in them, and thither referre the Reader for his better satisfaction. Hippocrates lib. 1. Epidem. sectione secunda, twice in that section. Lib. 3. Epidem. sect. 3. Galen lib. 6. de locis affectis. Cap. 4. Comment. ad Aphorif. 75. sec. 4. We may add to these if it were needefull, Auicenn, Paulus, Mesues, and many others.

Thirdly, this matter is purged by the Seidge, but Hippocrates, saith, It is very dangerous, yea mortall. Galen in his Commentary vpon Hippocr. de Coacis, It is a wonder (saith he) that Quitture or purulent matter should flow downe from the parts aboue the Midriffe into the belly, that is into the guts. Fourthly, this matter is purged by Apostemation (Physitians call that per abscessum) either of the lower or vpper parts. Hippocrates saith in Porphet. From a Peripneumonia or inflammation of the Lungs Apostemations doe breede vnder the eares, or in the lower parts and do there suppurate, and those men are deliuered from the disease. And againe in Coacis, Those apostemations that descend vnto the Thighes in such as are troubled with the Peripneumonia, are all of them profitable.

Thus many wayes therefore are numbred by Hippocrates, by which the purulent matter of the Chest is by Nature euacuated, first by the mouth, secondly by the kidnies, thirdly by the guts and lastly by Apostemation or abscesse. The first is safest and therefore chiefly to be desired, next that which is by the Vrine, for it bringeth least labour or trauell to the frame of Nature, that is to the due disposition of the bodie: onely it is troublesome, because it is painefull, as being accompanied with a Strangurie, yet not that continuall, but catching as it were and by turnes. That which is by the guts is the worst of all, for it breaketh or dissolueth the Faculties of the stomack, as well of Appetite as of Concoction, and of the guts also with his noysome stenche, and beside by the acrimony and ill quality of the matter, causeth an incurable bloody Flix. But that euacuation, which is by apostemation is profitable, if so be it fall into the lower parts, both because it is far remoued from the first diseased part, and also because that kinde of excretion is as the Physitians sayes, *αἰσίων* *περιβολῆς*, a conuenient kind of euacuation, and proportionable both to Nature and to the disease. For a lawfull Apostemation ought neither to be *ἡμίσπορος* nor *ἀνδροπορος*, that is, neither ought part of the matter flow to the place of Apostemation, but all; nor all take way vppward but downward onely; for to ascend is against the nature of the humour, and argueth alwaies a gadding quality therein. Ariteus in his Book de Morbis Chronicis addeth, that in women sometimes this purulent matter of the Chest commeth away by the wombe. Thus we haue declared all the manners of Natures worke in the euacuation of noisome humors out of the cavity of the Chest, but by what wayes and passages Nature deriueth them as it belongeth to a higher contemplation, so will it be harder to know, and when it is knowne more profitable. The vppward expurgation by the sharp artery or wezon is manifest enough, for when the Chest is dilated the Lungs are blowne vp, & like a sponge sucketh vp the matter wherein they lie soaked as it were in suds, & when the Chest is contracted the Lungs fall downe and so thrust out the purulent matter together with the smoaky excrements of the heart into the sharpe arteries, and they by continuity of passage into the weazon, and so it passeth to the mouth, and by coughing is excluded. But by what waies it goeth to the kidnies and so to the bladder is greatly controuerted. Erasistratus would haue it go by the right ventricle of the heart, & so into the hollow veine, & thence by the emulgent into the kidnies. It is sucked (saith he) first by the rare & spongie flesh of the Lungs, then by the arteriall vein, which is appointed for the nourishment of the Lungs, & thence is deriued into the right ventricle of the heart; out of it into the hollow veine, from thence into the emulgents, thence into the vreters, and so into the bladder. But this opinion of Erasistratus cannot bee true, because nothing passeth out of the arteriall veine into the right ventricle by reason of the membranes which are shut outward, and nothing goeth out of the heart by the hollow vein because of the three-forked membranes which shut inward. Mesues was of opinion, that this expurgation of purulent matter is by the veines, sometimes to the concauous part of the Lungs, & so by the seidge away, sometimes to the gibbous or conuex, and so by the kidnies. Fallopius that oculate Anatomist, thinkes hee found a neerer and more ready way, & for it describeth a small branch which runneth from the *Non-paril*, or *vena sine pari*, along by the ribs, and so pierceth the midriffe, & ioyneth it selfe with the fatty veine called *Adiposa* and the emulgent. This excretion of the pus or matter by the veines I doe not altogether gainsay, yet I thinke it to bee a

A mistaking of an apostumation of the heart.

Two Histories, *Hollerius*.

Laurentius

very vnconuoth way because their mouths open not into the chest, neither are the veins stirred with any motion whereby they might sucke so thicke and foeculent a matter, and that it should sweate through their coates is a very difficult matter and hard to be beleued. Some there are which dreame of certaine secret *meatus* or pores for this expurgation, because when men are aliue all passages yea euen substances are open, and the body perspirable yea almost perspicable both within and without.

True it is, that the body is so open; for wee know (as saith *Hippocrates* in his 2. Booke de *Morbis Epidemijs*, & the 55. Aphorism. sect. 7.) That nature maketh way for *Apostumations*, euen through the bones; the dropie water passeth out of the capacity of the abdomen into the guts and sometimes into the wayes of the vrine; the vrine is transcolated through the flesh of the kidneis, the seede through the substance of the testicles, the flegmatick humors of the ioynts sometimes are drawne into the guts, sometimes in a slimy spittle they are auoyded out of the mouth by vnctions of quick-silver. All these things I say wee admit, but why should we seek such insensible passages for this expurgation of purulent matter, when there bee many very patent and easie to bee perceiued? But what are they? Let vs heare *Galen* chalking them out vnto vs, in his 4. chap. and 6. Booke de *locis affectis*. This question (saith he) doth not a little trouble *Erasistratus* followers, who thinke that there is nothing contained in the arteries, but onely spirits; but to vs it is of no difficulty, because we vnderstand that the venall artery of the Lungs can leade so much of the purulent matter of an impostumation as it rescineth into the left ventricle of the heart, to bee thence conueyed into the kidneyes by the great Artery. His meaning therefore is, that the substance of the Lungs doth sucke vp the pus or matter and deliuer it vnto the venall artery, that, vnto the left ventricle of the heart, the heart vnto the trunk of the great artery, and that, vnto the kidneyes and so to the bladder by the vreters. And before *Galen*'s time *Diocles* acknowledged the same way of expurgation.

But let vs heare now the exclamations of some new Writers against *Galen*. How may it bee (say they) that so noysome purulent and mattery a humour can be purged through the left ventricle of the heart, the shop and worke-house of the vitall spirits, and through the arteries and store-houses of the same spirits, without great danger vnto the patient? Shall not the spirits which of their owne nature are most pure, bee infected and tainted in that medley? For if but a malignant vapor or poysonous ayre do breathe from a bone, or any vessell vp vnto the heart, straight we are ouertaken with a fainting or swoounding. Why therefore shall not an vsauory and noysome quitture or pus gotten into the very heart it selfe doe at least so much? But wee know nature to bee so wise and prouident that shee vseth not to moue her excretions but by wayes that are safe and auail: now who will call the heart and the arteries places safe or conduible to leade away such foeculencies? These and such like obiections they make who do not allow of the passages assigned by *Galen*. But they do not remember that it is one thing to bee done critically, and another thing to bee done symptomatically; one thing to be done by force & contention of Nature, another by force and contumacy of the malady; one thing to be done by a faculty, another thing by a disease: and finally, one thing by a strong and vigorous, another thing by a weake and feeble faculty.

If this transfusion of the purulent matter bee criticall and the spirits strong, then is this passage by the heart without any damage to the patient, for nature retaineth and preferueth the spirits and auoydeth onely that which is hurtfull. But if the strength bee feeble, then doth the patient dye in the very expurgation; and if you cut him vp when hee is dead, you shall finde the left ventricle of the heart full of purulent matter; which deceiueth many vnskilfull people, who cry out that his heart was apostumated.

Finally, beside the authority of *Galen*, in his Commentary In *Coacas praeotiones*, and Anatomical demonstration, I will adde for confirmation of this poynt two Histories. The first *Hollerius* reporteth where hee treateth of the heate of the vrine. A certaine woman (saith he) with intolerable torment did make a purulent water; after the fourth month shee dyed and was opened: there were found in her heart two stones, with many small *Apostumations*, the Kidneyes and all the wayes of the vrine being found. Wherefore this purulent matter was purged by the great artery.

Of the other History *Laurentius*, one of our trusty guides in this trauell, is a witnesse. An honest Citizen of *Mompelien* in *France* was sicke or indisposed with a hypochondriacke melancholy for 3. yeares, and the disease grew sharpe, for at length an acute Ague ouertooke him and hee dyed, but a whole month before his death twice in a day lightly hee was troubled with a light swoounding or fainting with some little heate of his vrine, and an incredible

dible desire of making water, but after he had auoyded a thinne, red and stinking vrine, hee came presently againe to himselfe.

After hee was dead and opened, we found the whole cavity almost of his chest filled with that thinne, red and abhominably sented humour, and the like wee found also the left ventricle of his heart to be full of, which, sayth *Laurentius*, when I saw and wondred at, presently the place in *Galen* before quoted came into my minde, and in the presence of some maisters in Chirurgery and many young students in phisicke, I opened, that the cause of his frequent defections and vnconstant strangury was to be referred to the transfusion of the virulent matter through the left ventricle of the heart and the arteries; which my opinion they all applauded; because the humour contayned in the chest and the vrine that hee auoyded in his defections or swounds, were both of a colour, substance and fauour. And thus much to redeeme *Galen* from the vniust imputation layd vpon him by some, otherwise not vnlearned, but in this not so considerate as I thinke they ought to haue beene.

QVEST. VIII.

Of the Temperament, nourishment, Substance and Flesh of the Heart.

Concerning the Temperament of the heart, the Physicians are at great strife among themselves. *Auerrhoes* was of opinion, that the heart of his owne nature was cold, because his greatest part consisteth of such things as are naturally cold, as immovable fibres, foure great vessels which are spermatieall parts & without blood and cold; and that it is hot by accident onely, by reason of the hot blood and spirits contained in it and his perpetuall motion.

This opinion of *Auerrhoes* his followers strengthen with these reasons. First, because the flesh of the heart is thight and solid, & nourished with solide, thicke and cold blood. Secondly, because at the Basis of the heart which is his noblest part, there groweth a great quantity of fat, whose efficient cause (saith *Galen*) is cold. Lastly, because it is the store-house of blood; now blood (saith *Hippocrates* in his Booke de Corde) is naturally cold, for as soone as it is out of the veines it caket. But to the first argument we answered, that the fibres and the vessels are not the chiefe parts of the heart, but the flesh: and therefore *Aristotle* and *Galen* call it a fleshy viscus or bowell. *Hippo.* a muscle. To the second, that the fat groweth not in the ventricles, nor about the flesh of the heart, but onely about his Membrane, which in respect of his flesh is but a cold part: beside, Natures finall cause, that was to keepe the heart from torrifying, ouercame all the rest; which thing in nature is not vnusuall. To the third we answered, that there are two sorts of blood, one venall and another arteriall; the venall indeed is lesse hot, but the arteriall blood is exceeding hot. Now the heart is the shop or worke-house of arteriall not of venall blood.

Wee conclude therefore that the heart is not onely hot, but of all the bowels the hottest, which wee are able to prooue by authorities, reasons, and experience. *Hippocrates de principis* saith, There is much heate in the heart, as being of all members the hottest. *Galen* in the last chapter of his first booke de temperamentis: The blood receiveth his heate from the heart for that of all the bowels is by nature the hottest. The reason is, The heart is the fountaine of heat and of the Nectar of life: it ingendereth the arteriall blood, the venall it attenuateth for the Lungs; heere the vitall spirits the hottest of all others are made. Finally, heere is the hearth and the fire whereby the naturall heate of all the parts is refreshed. Add experience also. For if you put your finger into the heart of a beast suddenly opened, the heat of it will euen burne. So also *Galen* saith in his first booke de semine. Againe, the flesh of the heart is the most solid of all flesh, because it is ingendered of most hot blood, made dense and thicke by the parching power of an exceeding great heate. But some will say that the spirits are hotter then the heart: I answered, it is true that in the spirits there is a greater heat, but in the heart there is more heat, more sharpe and which heateth more, because of the density of his substance; so fire in straw or stubble though it bee a flame burneth but lightly, for you may draw your hand through it without any great offence; but hot glowing yron although it haue not the same degree of heat that the flame hath, yet it burneth more strongly and cannot bee touched without danger. But it may be demanded, if the spirits bee hotter then the heart and are bred in the heart, whence haue they that greater heate? I answered, The heart consisteth of three parts as it were or substances; a spirituall, a moyst and a solid. The spirits

are ingendered of the spirituall and hottest part of the heart, and are hotter indeed then the whole heart, but not hotter then that part that ingendereth the spirits. That this may be, *Galen* giueth an instance in milke: milke in his whole substance is either cold or temperate, but his fatty and buttery part is hotter then the whole body of the milke; so the heart is hot in his whole substance, but the spirituall part of the heart is hotter then the whole heart, and from that part haue the spirits their intense heat: and thus much of the actiue qualities of the heart. Now for the passiue there is as great dissention. *Auicenna de Temperamentis*, and *Galen* in his second Booke *de Temper. Cap. 3.* and 12. and in his 3. Booke *de Aliment. facultatibus* say it is dry, and his flesh hard and solid; now it is a sure rule *That whatsoeuer is hard to feele too in a liuing body, that also is dry.* On the other side *Auerroes* will haue it moyst, because life consisteth in heat and moysture, but the heart is the beginning of life and the shop of moysture. *Galen* in the last Chapter of his first booke *de Temperamentis*, calleth it a Bloody Bowell, therefore moyst, and in the same Chapter, *it is a little lesse dry then the skinne*, therefore moyster then the skinne. I answer, it is true that the heart is moyster to feele too then the skinne. But *Galen* when hee sayeth it is drie, compareth it not to the skinne but to the parts, for so his words are. *The flesh of the heart is so much dryer then the flesh of the spleene or kidneyes, as it is harder.* And so much of the Temperament of the heart.

Concerning his nourishment, *Galen*, in his first Booke *de vsupartium*, and the 7. *de Administr. Anatomicis*, sayeth it is nourished with venall and thicke blood; many of the latter writers say it is nourished with the thinne blood containd in his ventricles. On *Galen's* side, that is on the truths, are these reasons. It is a Catholicke principle, *Euery thing is preserved and refreshed with his like.* The flesh of the heart is hard, thicke and solide, such therefore must bee his nourishment: beside there is a notable veine called *Coronaria* or the Crowne-veine, which compasseth a round the Basis of the heart and sendeth forth branches into all his substance; but Nature vseth not to doe any thing rashly or in vaine, it serueth therefore for his nourishment: beside ocular inspection prooueth it which no reason can conuince. The branches of the coronarie veine are more and more conspicuous on the left side of the heart then on the right, because the thicker part wanteth the more nourishment. But the aduersaries say that the outward part is onely nourished with this veine, the inward with the blood containd in the ventricles: for say they, this veine is too little, to nourish the whole heart being a very hot member and in perpetuall motion; beside the veine looseth it selfe in the superficies of the heart and passeth not into the ventricles. But for the narrownes of the veine I cannot perceiue it is so small as they talke of; and for this motion it is true, yet there are many things that temper it, on the outside it is couered almost with fat, and compassed with a watery humour, and within it hath abundant moysture whereby though it bee not nourished yet is it watered and kept from drying and flaming; as boyling hot water keeps a vessell on the fire from burning. And whereas they say the branches of the coronarie veine passe not into the ventricles, I answer, that neither are the vesselles dispersed into the inner substance of the muscles and the bones. *Hippocrates* sayeth *That flesh draweth from the next vessels.* If you would faine reconcile the new writers to *Galen*, you may say: That haply the inward parts of the heart are nourished with the blood containd in the ventricles but not yet attenuated, for why should the inward parts be nourished with rarified blood and the outward with crasse and thicke; seeing the nature of the inward flesh and outward is all one? and so much of the nourishment of the heart.

Now for the substance and flesh of it, some say it is musculous, but that we haue answered before in the description; briefly thus: *Hippocrates* in his Booke *de Corde* calleth it a strong muscle: againe it is moued by a locall motion and so are none of the other bowels, as the Liver, the Spleene, the Kidneyes, &c. but all muscles are so moued. Moreover, the flesh of the bowels is simple and similar, but the flesh of the heart not so but wouen with threds and fibers like that of the muscles, therefore it is a muscle. *Galen* on the contrary will haue it no muscle, for that muscles haue simple fibres but the heart manifold, the muscles haue but one and that a simple motion, for they bow or stretch forth, lift vp or pull downe; but the heart hath diuers yea contrary motions: and this is a very powerfull argument which yet some seeke to ouerthrow: because say they, there bee many muscles which haue diuers kinds of fibres, & also diuers yea & contrary motions; as the *Pectorall* muscle which hath diuers fibres & moueth the arme not vpward and downward onely but forward also; & the muscle called *Trapezius* which moues the shoulder-blade not only vpward & downward but back-

backward also; and therefore the variety of his fibres and the diuersity of his motions do not exempt him from the number of muscles.

I answer for *Galen*. Those two Muscles aboue named haue indeed diuers motions but not from the same part; but from diuers parts of the muscle; for they haue diuers originals or beginnings. The *Trapezius* ariseth from the back-part or nowle of the head and from the rack-bones of the backe; by the former part it moueth vpward, and downward by the latter. The *pectoralis* also hath diuers beginnings, for it ariseth from the Throate and from the whole breast-bone; wherefore these muscles doe not pull down with the same part where with they lift vp, but the heart is dilated and contracted in the same part; there is not therefore a like reason of their motions. The like may be said of their fibres; for the fibres of those aboue-named muscles though they be of more kinds then one yet are they distinct; the fibres of the heart are wouen together and confounded that no art or industry can pare them. The fibres of the muscles are diuers in their diuers parts; but those of the heart are all in euery small part of the heart.

Moreouer, the taste of the heart and of the muscles is not one saith *Galen* in the 8. Chap. of his 7. Booke de *Administrat. Anatom.* *Anicen* saith the muscles are weary, the heart neuer; yet this seemeth to be no sound reason, because the midriffe which is a very strong muscle mooueth perpetually: but *Anicen* hath another reason for *Galen's* opinion of more force which is this. The heart is no muscle because his motion is not voluntary, for we can neither foreflow nor hasten, neither stay nor stirre vp his motion as we may the motion of the midriffe and of all the other muscles. We conclude therefore with *Galen* that the heart is no muscle, but either an affusion of blood which *Erasistratus* called *parenchyma*; or some peculiar flesh. How *Hippocrates* is to be vnderstood we haue said before, to wit, abusiuely; it is musculous because it is red and fibrous, but not a muscle. But it will be objected it is moued with locall motions, therefore it is a muscle.

I answer, that by the same reason should the womb be a muscle, for we haue shewed how that is moued euen locally sometimes, as when it closeth in conception, or is dilated in the birth: and the guts haue a locall motion called *motus peristalticus*; which no man will say is a voluntary motion or that therefore they are muscles.

To the other argument we say, that the flesh of the hart though it be fibrous yet it is simple, because the fibres are of the same substance with the flesh of it as the fibres of the stomacke, the wombe and the guts; but the fibres of the muscles are particles of nerues and tendons much vnlike their flesh: and this indeed is *Galen's* answer in his 2. Booke de *temperamentis*; yet we affirme that the fibres of the heart are stronger and harder then the rest of his flesh, which maketh it strong and better able to indure his perpetuall labour.

But why is the flesh of the heart more fibrous then that of the Liuer or kidneyes? *Galen* answers, *The fibres of the heart are made for necessary uses of traction retention and expulsion by the right it draweth in the Diastole or dilatation, by the oblique it retaineth, and by the transuerse it expelleth in the Systole or Contraction.*

QVEST. IX.

whether the heart will beare an apostumation, solution of continuity or any grieuous disease.

He last question concerning the heart shalbe whether it will beare any notable disease or no. *Hippocrates* saith (in his booke de morbis.) *The heart is so solid and dense that it is not offended with any humor, and therefore it cannot be tainted with any disease.* *Aristotle*. *The heart can beare no heauy or grieuous disease because it is the originall of life.* *Aphrodisias*. *In the heart can no disease consist, for the patient will dye before the disease appeare.* *Paulus*. *Any disease of the heart bringeth death head-long vpon a man.* *Pliny*. *Onely this of all the bowels is not wearied with diseases, neyther indureth it the grieuous punishments of this life; and if it chance to bee offended present death insueth.* Yet how repugnant this is to experience many Histories doe beare witnesse. *Galen* (in his 2. Booke de *placitis*) reporteth that a sacrificed Beast did walke after his heart was out, and in his seuenth Booke de *Administra. Anatom.* he maketh mention of one *Marullus* the sonne of a maker of Enterludes, who liued after his heart was laide bare euen from the puffle or *pericardium*, and (in his 4. Booke de *locis affectis*) if a man be wounded in the heart, and the wound pierce not

into the ventricles but stay in the flesh, hee may liue a day and a night. *Beneuenius* writeth that he hath seene many Apostemations in the heart. Wee told you a story euen now out of *Hollerius* of a woman who had two stones and many Apostemations found in her heart.

How these are
to be reconciled.

Galen interpreted

Answers to
the examples.

A strange story
of a Florentine
Ambassador in the
Court of
France.

Matthias Cornax Physitian to the Emperor *Maximilian* saith, that he dissected a Booke-seller, and found his heart more then halfe rotted a way. *Thomas a Veiga* writeth, that there was a red Deere found, in whose heart was sticking an olde peece of an Arrow wherewith hee had beene long before wounded in hunting. But you shall reconcile these together, if you say the heart will beare all afflictions, but not long; or that it is subiect to all kindes of diseases, but will beare none greeuous. For example, the heart will suffer all kindes of distemper, but if any distemper be immoderate or notable the party presently dies, so sayeth *Galen* in his fift Booke *do locis affectis*, Death followes the immoderate distemper of the Heart. When *Galen* saith, in the fift Chapter of his first Booke *De Locis Affectis*, That the heart will beare no Apostemations, he vnderstandeth such an apostemation as comes by the permutation of an inflammation. For the Creature will dy before the inflammation will suppurate or grow to quittance. Say that the Apostemations found by *Beneuenius*, *Hollerius* and *Mathew Cornax* were Flegmaticke; or say, that rare things do not belong to Art; or with *Auerrhoes*, as in Nature so in diseases we oftentimes find Monsters. That a creature can walk and cry when his heart is out I beleue well so long as the spirits last in his body which it receiued from the heart, when they faile he presently dieth.

Andreas Laurentius maketh mention of a strange accident which happened in the Court of France, *Guichardine* a Noble Knight and Ambassador for the Duke of Florence beeing in good health and walking with other Noble-men, and talking not seriously but at randon, presently fell stone dead neuer breathing and his pulse neuer moouing. Many tolde the King, some saide he was dead, some that he was but falne into an Apoplexie or a Falling sicknesse, and that there was hope of his recovery; The King (saith *Laurentius*) commanded me to take care of him; when I came, I found the man starke dead, and auouched that the fault was not in his braine but in his heart. The next day his body was opened, and we found his heart so swelled that it tooke vp almost his Chest; when wee opened the Ventricles, there yssued out three or foure pound of blood, and the orifice of the great Veine was broken, and all the forked Membranes torne, but the Orifice of the great Artery was so dilated that a man might haue thrust in his arme. So that I imagine, that all the Flood-gates being loosened, so great a quantity of blood yssued into the ventricles that there was no roome for the dilatation or contraction, whereupon he fell suddenly dead; yet is it a great wonder how without any outward cause of a stroke, or fall, or vociferation, or anger, so great a vessell should be broken. It may bee he was poisoned, for the Italians they say are wondrous cunning, and in the Contention of Nature that dilaceration hapned.

QUEST. X.

of the difficulties
about the motion
of the heart.

And thus much of the proper motion of the Heart, what causes it hath, what manner motion it is, what power or faculty mooueth the Arteries, when and as the heart is mooued; or after and otherwise: How and where the vitall spirits are generated and their immediate matter prepared, what is the temperament of the heart, how it is nourished, what his structure is, and how many the parts of his substance are with their vse and functions: Finally, how able to beare and endure affects and diseases. The resolution of which questions, though they do not properly pertain vnto Anatomy all of them; yet do they so depend one vpon another as that it seemeth necessary that he that would know one should also know all; notwithstanding in our treating of them we haue very often restrained our Discourse and conteyned it within such limits as are not farre distant from Dissection it selfe.

Of Spiration.

Why necessary

It remaineth now, that we should a little stand vpon another motion in our bodies, and the Instrument thereof which Nature hath ordained to be seruiceable to this motion of the heart, and that is Spiration or breathing. For the Heart being exceeding hot and therefore a part of great expence, needed a continuall supply of nourishment for the spirits, and of ventila-

tion for himselfe. For *Hippocrates* saith in his Booke *De Natura pueri*, *Calidum omne frigidum moderato Nutritur & fouetur*: That which is hot is nourished and cherished by that which is moderately colde: which sentence *Galen* in his Booke *de usu Respirationis* thus elegantly expoundeth; Euen as (saith he) a flame shut vp in a strait roome and not ventilated with the aer burnes dimmer and dimmer till it be extinguished, so our naturall heate if it want cold to temper it growes faint and wasted away to vtter confusion. For it is like a flame mooued both wayes vpward downward, inward and outward; vpward and outward, because it is light as being of a fiery and aery nature; downeward and inward in respect of his nourishment; either of these motions if they be hindered, the heate either decayeth or is extinguished; it decayeth for want of nourishment because it cannot be mooued downeward and inward. It is strangled and extinguished when it cannot be mooued vpward and outward and so refrigerated.

Wherefore, the spiration or breathing of colde is very necessary for the preservation of naturall heate; but what shall this colde be? Surely either aer or water: aer is more necessary in perfected and bloody creatures, first because it sooner followeth the distention of the brest and so the dilatation of the Lungs, and filleth all that is dilated to keepe out vacuity; secondly it cooleth sooner, as better distributing his parts into euery secret corner of the heart: finally it is better expired or breathed out then water, though it be not more easily drawne in. Aer then is the best cooler for the heart, and that must be brought vnto it by breathing: now this spiration or breathing is double, insensible and sensible; Insensible spiration *Hippocrates* and *Galen* call properly *σπέρσις*, and the Latins *Perspiration* and *Transpiration*. The other and sensible breathing is called *ἐνσπνοή*, that is, *Respiration*. Transpiration is by the secret pores of the skin, Respiration by the mouth and the nose. Those creatures whose heate is weake and faint do liue onely by Perspiration, so all that are without blood or which we call *Insecta* of certaine diuisions they haue about their necks or bellies; so the infant in the womb transpireth onely but doth not respire, and many women in fits of the Mother (the natural heate of their hearts being dissolved by a poisonous breath arising from putrified seedes) do liue a while in trances only by Transpiration. But those creatures whose heat is neerer to the nature of flame, by transpiration onely cannot be tempered. Wherefore such heate needeth a farther helpe to waste more aer vnto it, and that is done onely by Respiration.

Whether aer or water is fittest to coole the heart.

Transpiration and Respiration.

Fittes of the Mother.

The parts of Respiration.

This Respiration therefore hath two parts, Inspiration and Expiration; Inspiration is the drawing in of the aer, Expiration the breathing it out. Inspiration is like the *Diastole* of the heart, Expiration like the *Systole*.

This Respiration whether it be Naturall or Animal hath troubled the heads of Schollers a great while, and would also now trouble ours if we should muster together all the Reasons which are brought on both sides; yet because the question is worthy the decision wee will breiefely as we can resolue it with your patience. The arguments to prooue it not to be Animall or voluntary are. First because voluntary actions are from election: but men asleepe (when yet there is respiration) haue no election, no will, because sleepe is a rest or cessation of all Animall actions. Hence it is that *Galen* calleth the *Caras* a sleepe disease *Privationem Animalitatis*, a priuation of all the animall Faculties; yet in that disease the Respiration is free: as likewise in the Apoplexie which is a resolution or palsie of the whole body. Now where is no sense remaining, can there then remaine any voluntary motion? yet we see Respiration remaineth.

Whether Naturall or Animall.

Not Animall. The reasons.]

Againe, to be voluntary and perpetuall are contraries; for voluntary actions do all breed wearinesse, but Respiration breeds not wearinesse in the motion, but if the motion be any whit checked or stayed, that stay or checke breeds wearinesse: Finally when the Respiration is vitiated we apply remedies vnto the region of the braine, which is the originall of voluntary motion. On the contrary, the great argument to prooue it to be voluntary is, that we can breath when we will, and when we will we can stay our breath: so as many haue thus voluntarily ended their dayes, I meane by staying their owne breath. *Galen* in his second Booke *de Motu Muscularum* telleth of a Barbarian seruant, who being throughly angred purposed to lay violent hands vpon himselfe, hee threw himselfe therefore vpon the ground, and held his breath a long time remaining vnmoued, at length turning himselfe a little he breathed out his life.

That it is Animall.

Histories.

C. Licinius Mator a Pretorian Citizen of Rome, being accused for oppression by exactions, whilest the Iudges were giuing sentence shut vp his owne mouth, and couering it

with his Handkerchiefe reteyned his breath till hee fell downe dead.

Coma the brother of one *Maximus* a Captaine of Out-lawes, when he was asked concerning the strength and enterprises of the Fugitiues, gathered his strength together, covered his head, and falling vpon his knees held his breath till he dyed euen in the hands of those that guarded him and before the face of the Iudges.

Cato Uticensis, when his sonne had taken away his sword, hee perswaded his Seruants to giue it him againe, saying he would keepe it for his defence, not to murder himselfe with. For sayeth he, *If I list to die, I could easily hold my breath to serue that turne*: Besides, *Hippocrates* sayeth in his third Section of the second Booke *Epidemian*, that the cure of continuall yawning which Physitions call *oscitation*, is long breathing: and *Aristophanes* in *Plato* his *Symposio*, being troubled with a hiccock, intreated *Erismachus* the Physition to tell out his tale for him, *That will I saith he, and in the meane time hold your breath some good while and your hiccock will cease, and then you shall take my turne as I haue taken yours*. Wee may then reteyne our breath when and how long we will and therefore it is a voluntary action. For the instruments whereby we breathe are all Animal, as the *intercostall* muscles, the midriffe which is also a muscle, and the nerues. Finally, if the braine bee offended as in a phrensie, then is the Respiration offended.

We see here two opposite opinions, both which we cannot maintaine vnlesse they will either of them remit somewhat and yeeld a little either to other, and then it will not bee hard to reconcile them after this manner. Some actions are purely and simply Naturall, as Concoction, Nutrition &c. Some partly voluntary, as speech and walking. Some mixt, that is partly Naturall partly Animall, as the auoyding of water and excrements, as *Galen* sayeth in the fourth Chapter of his 6. Booke *de locis affect*; and in the sixt Chapter of his second Booke *de motu musculorum* he likeneth Respiration to these. Respiration therefore is a mixt action, partly Naturall and that in respect of the finall cause and of necessity, partly Animall in respect of the instruments of it, the museles.

Those that are strangled do not breathe because they cannot Animally; the nerves and muscles being intercepted with the rope. *Hysterical* women that are troubled with the *mother* do not breathe, because they cannot naturally: for there is no use of respiration, nor no necessity vrging it although the instruments bee at liberty; and Nature hath here very wisely ordayned that although this action were absolutely necessary and so naturall for the preservation of life; yet there should also be in it some command of the will, because it is often very profitable to stay the breath and often to thrust it out with extraordinary violence.

If wee be to giue very diligent eare to any thing, if to passe through any vsauoury or noysome places, if we fall or be throwne into the water, it is very necessary that we should bee able to conteyne our breath : on the contrary, to blow vp any thing, to winde a horne or found a trumpet, to blow the fire or such like; it is very profitable that we should bee able to breathe with extraordinary violence. Now in a word we will satisfie the arguments on both sides; and to the first in the first place.

They say that men Respire when they sleepe, but in sleepe there is no vse of election or will. I answer there is a double will, as *Scaliger* sayeth, *One from election proper to men and men awake, the other from instinct, and this is in men asleepe and in brute beasts.* The motion of respiration when we sleepe is by instinct, neither are all the Animall faculties idle in sleep, or extinguished in the *Caros*, *Epilepsie* and *Apoplexie*; but in sleepe they are remitted as *Galen* sayeth, not intermitted (for euen the muscles haue a motion which wee call *Tonicum motum*, *A rigid motion*, especially the two sphincter muscles) and in the diseases they are depraued.

The reason why we are not wearied with continuall respiration, is because there is continuall vse and necessity of it, although it cannot be denied that euen respiration being constrained wearieth the creature much.

On the contrary, they that affirme this respiration to bee meerely voluntary, alleadge that we are able to stay it when we will and to moue it when we will; to which I answer: That is properly and absolutely a voluntary action which may bee stayed at our pleasure when it is doing, and againe done when it is stayed; but respiration is no such action: for if the Respiration be altogether stayed, as in those whose histories are aboue mentioned, then is the creatures life extinguished and the respiration cannot againe bee mooued. And for the two other arguments that respiration is by Animall instruments, and that in a phrensie which

which is a disease of the brayne, the respiration is vitiated. I answered, that they proue indeed that in respiration there is somewhat voluntary, but they doe not proue that there is nothing naturall. Wee therefore do determine that Respiration is a mixt action, and to it do concur both principles ioyned together, the Brayn and the Heart, the Animall and the Naturall faculties.

The determination.

To conclude this Chapter and discourse of Respiration: The pulse and respiration wee see are two distinct motions, yet so neare of kinne as men doe not ordinarily obserue the differences betweene them: wee will therefore in a word tell you wherein they differ and wherein they agree.

How the pulse and respiration differ.

They agree in that that they both serue one faculty that is the Vitall; for they were both ordained onely for the heart which is the seate of the vitall faculty. Moreover, they haue both one finall cause a threefold necessity; of nutrition, Contemperation and expurgation: nourishment of the spirits, Contempering of the heat and purging of smoky vapors. Thirdly, they agree in the condition of their motions, for both of them consist of a *Systole* and a *Diastole*, and a double rest betweene them: but in these things they differ. That the pulse is a Naturall motion, continuall not interrupted, and without all power of the will. Respiration is free, and ceaseth some whiles at our pleasure; the efficient cause of the pulse is only Nature, of Respiration Nature and the Soule together; the instruments of the pulse are the heart and the arteries, of Respiration the muscles: the pulse is from the heart, Respiration not from the heart but for the heart. Finally, the heart beateth five times for one motion of Respiration.

Lastly, whether is the pulse or Respiration more necessary or more noble? More noble surely is the pulse, because his instrument the heart is more noble, his effect the vitall spirit is more noble then the ayre; and the end is better then that which serueth for the end: but Respiration was made for the preservation of the pulse: but now for their necessity there needeth a distinction. There is one pulse of the heart and another of the arteries; the pulse of the heart is more necessary for life then Respiration, but the particular pulsation of the arteries is lesse necessary then Respiration; for though the arteries be bound or intercepted the creature dyeth not presently, but if the Respiration be stopped hee is presently extinguished.

Whether is more noble & necessary the pulse or respiration.

QUEST. XI.

Of the Temperament and motion of the Lungs.

Concerning the Temperament of the Lungs, there is question among the Masters of our Art. Some hold them in the active qualities to be cold, others to be hot. Those that would haue them cold giue these reasons for their assertion.

Of what temper the lungs are. That they are cold. Reasons.

First, because their whole frame and structure consisteth of spermatical that is cold parts: these are, the gristly artery, the arteriall veine: and the venall artery.

Secondly, because they are made to refrigerate the heart, wherefore they are called the *Fanne of the heart*.

Thirdly, because they are subiect to colde diseases, as obstructions, shortnes of winde, difficulty of breathing, and knottines called *Tubercula*.

Fourthly, because they abound with flegmaticke and cold humors, which is discerned by that we cough vp.

Lastly, they alleadge an authoritie and a reason out of *Hippocrates*, the authority, for that he sayth, *The Lungs are of their owne nature cold, and are farther cooled by inspiration*. *Hippocrates* ground out of which they draw this argument is where he sayth in his Book de *Alimentis*, *The Lungs do draw a nourishment contrary to their body, where as all other parts draw that which is like to them*. From whence they reason thus. The Lungs draw vnto themselves blood attenuated in the right ventricle of the heart and are therewith nourished. That blood being very hot, their substance (if *Hippocrates* sayd true, who is saide neuer to haue deceiued any man, nor neuer to haue beene deceiued himselfe) must needs bee cold. But these arguments may thus be answered.

Authority.

A reason drawne from Hippocrates.

Answer to the arguments.

To the first, the vessels are not the substance of the Lungs but the flesh; which is made of a hot and frothy blood.

To the second, that they refrigerate and coole the heart not by their own Temperament, but because they draw and containe outward ayre, which is alwaies colder then the heart though it be neuer so soultury hot.

To the 3. that their vessels because they are many and diuersly implicated are subiect to obstructions, but their flesh which is their true substance is subiect to inflammations and hot affects.

Whence the
phlegme com-
meth that wee
cough vp.
How it be-
commeth
white.

To the fourth, that the aboundance of flegme which we cough vp, is not generated by the native temper of the Lungs but falleth continually from the head which is the receptacle of cold excrements into the Lungs; so saith *Hippocrates*, *Many Catarrhes or Rheumes fall into the upper venter*, that is the Chest. The lower part also as the stomacke and the *Hypochondria* do send vp plentiful vapors which the Lungs with this continuall motion do mixe with the foresaid humor and thence cometh the whitenes. And as for *Hippocrates* authority it may bee answered that hee compareth the temper of the Lungs with the temper of the heart, and then indeede they are cold, as also the aer of a hot-house is cold in respect of the heart.

Hippocrates
expounded &
retorted.

In the other place we say that *Hippoc.* speaketh of the aer inspired or breathed in, not of blood; and so that place proueth that the Lungs are hot rather then cold, because they draw aer which is cold and contrary to their body which is hot. But the truth is, that the contrariety he speaketh of in that place is rather a contrariety of motion; as if he should say, other parts draw a nourishment like vnto themselves from an inward store-house which is the Liuer into the very vtmost parts of the body; but contrariwise the Lungs draw the nourishment of the spirits, that is, the aer by the outward parts, that is, the nose and the mouth into the inward, that is, the heart. Although I am not ignorant that *Galen* interpreteth those words otherwise which shall not be necessary to make mention of in this place.

That the lungs
are hot.
3. arguments.

It seemeth therefore that the Lungs are not cold, which yet will better appeare if we can proue them to be hot. Three arguments we will be contented with; one from their substance, another from their nourishment, and a third from their vse. Their substance is fleshy soft and spongy, made as it were of the froth that ariseth of the hot blood in the boyling; therefore not cold. Againe, they are nourished with thin blood heated and attenuated in the right ventricle of the heart, which seemeth to haue beene made especially for the lungs sake. Lastly, their vse is to prepare aer for the generation of the vitall, that is, the hottest spirit; they must therefore be hot. Thus Physitions reason on either side. I will onely heere put a doubt, reseruing the determination to another place.

A notable
doubt put.

The Rheume falleth out of the head, part into the Lungs and part into the stomacke; Nature in both places worketh vpon it. The stomacke boyleth it againe, attenuateth it if it be thick, and of some part of it maketh good blood; the rest it auoydeth into the guts where another vse is made of it; and if the heate of the stomacke be languide and weake so that it cannot sufficiently mitigate it, we then helpe Nature.

Why the
Rheume must
be thickened
before it bee
coughed vp.
Whence dry
coughes come.

The Lungs quite contrary do thicken that part which falleth into them and that necessarily, for else it could neuer be auoyded; for it must be a solid body that the aer must lift vp before it in our coughing, because there is no passage for it downward appointed by Nature, and therefore it is that thinne and subtile Rheume maketh a dry cough because the aer is not able to intercept it, but it trickleth downe the sides of the weazon still prouoking vs to cough, but in vaine because it hath not a compacted body which aer might intercept till by time it be ripened, that is, grow thicke and then it is brought vp; or if of it selfe it do not thicken we thicken it by Art. We may therefore iustly wonder at this contrary worke of Nature; surely coldnesse in the Lungs can not thicken it, it being so neere to the fountaine of heate, nor the ayer which is the moistest of all Elements cannot dry it: besides that, the Lungs are of themselves very moist as we shall prooue by and by. Againe, if heate in the Lungs do thicken it, why should it not thicken it also in the stomacke; but we see that cold stomacks doe onely make thicke and viscid flegme.

A mystery of
Nature.

Truely heereunder lyeth a great mystery worthy of another place to be discussed in, to which therefore we will referre it and proceede to the second qualities of the Lungs, and enquire whether they be moist or dry. It may seeme they are dry, because their passages doe alwayes remaine open and neuer fall together, which is an argument of their hardnes and drynesse. Againe, *Galen* saith (in his 4. Booke *de usu partium*) they are nourished with chollericke blood, but chollericke blood is dry. Lastly, *Hippocrates* saith the Lungs are the seate of drought; for hee appointeth two places of drought, the stomacke and the Lungs.

That the
lungs are dry.
Arguments.

Con-

Concerning which, is that notable edict of *Hippocrates* (in *Epidemics*.) The way to appease and satisfie thirst is to drinke cold water and to breathe in cold aer. These arguments wee will first answer before we determine the contrary,

To the first we answer, that if the openness of their passages argue their driness, then should the braine also be dry whose ventricles are alwayes open and do not fall together in the strongest concussions or motions of the head, as in sneezing and fits of the *Epilepsie* or falling sicknesse. As therefore the braine is harder in the ends of the ventricles thereof (in which respect Anatomists call that part the Callous body as we shall heare heereafter): So the Lung where it compasseth the vessell is somewhat harder: or say rather, that the stiffness and hardness of the branches of the Sharpe and Rough Artery do hold it out and keep the passages in a kinde of distention.

To the second we answer, that *Galen* by bilious or Cholericke blood meaneth thin and attenuated blood laboured in the right ventricle of the heart, which no man will say is drie but rather abundantly moist, as being mingled with aer the moistest as we saide of all Elements. To the last we answer, that the Lungs indeede if they be torried are the seate of drought, because they dry vp the moisture of the heart and the parts adioyning; but if they be naturally disposed they are no cause of drought. It remaineth therefore that the Lungs are not dry, and then they must needs be moist; which yet further to prooue we want not arguments beyond all exception. First, because they are soft; for as hardness is a sure note of driness so is softnesse of moisture, but the substance of the Lungs is soft and lax, of which the very touch is a sufficient witness. Besides *Galen*'s authority is plainly for it, where he saith in his 4. Booke de *usu partium*, *The flesh of the Spleene is soft indeed and lax, but nothing to the substance of the Lungs which is the softest, the loofest and the lightest.*

Auicenna interposeth saying, *That the flesh of the Lungs is not soft of his owne nature but by accident or event*, because they ly steeped and drunken as it were in the moisture which falleth from the head, therefore he saith they are *not soft but madid*; which if it were so, then would they be drier in those bodies that haue dry braines, and moreover would in al other bodies become drier, as the moisture which falleth from the head is exhausted and dried vp, both which are contrary to all experience. We therefore conclude that the Lungs are naturally moist, and by so much moister then the liuer by how much they are softer. And thus much of the temperament of the Lungs, now followeth their motion.

Concerning which I find three opinions; one of *Aristotles*, another of *Auerroes*, the third of *Galen* and the Physitians. *Aristotle* in the 6. Chapter of his third Booke *De Part. Animalium* thinketh, that they haue the originall of their motion from the heart on this manner. The heate of the heart being encreased, with a kinde of violence listeth vp the Lungs and then aer entrieth for the auoiding of vacuity and emptinesse that infest enemy of nature; the colder aer setleth the boiling of the heate, as we see cold water beeing powred to boyling water setleth it; as therefore in the diffusion of the heate the Lungs are dilated, so the heat residing or setling they are contracted and the aer expressed or driuen out. *Auerroes* ioyneth so far with *Aristotle* that he thinketh the heate to be the author of Respiration, but hee saith that the Lungs follow not the motion of the Chest, but are mooued by a proper and peculiar power of their owne, because else there should be a violent motion which should be perpetuall, that which is vtterly against the rules of nature. True it is (saith he) that there is a wonderfull consent betweene the Chest and the Lungs, which is the cause that one of them cannot mooue or rest but when the other mooueth or resteth, yet neither of them is cause or originall of the others motions. The third opinion is of *Galen* and the Physitians to which also wee encline, who thinke the Lungs are not mooued by an inbred or proper power of their owne, for where are their Fibres and the strength of Filaments or strings for that purpose? Neither by the faculty of Pulsation which ariseth from the heart by which the arteries are mooued, and that because the motion of the Lungs sometimes doeth intermit, sometimes is quicker and slower as we list: neither by the animall faculty because there be no Muscles: but we conceiue that the Lungs are mooued by an accidentary motion, as following the motion of the Chest to auoid vacuity. For when the Chest is distended the Lungs are filled with aer and enlarged, and when that is contracted they are emptied and fall, *Galen* establisheth this his opinion with this reason, because there is no disposition of the body found wherein the Lungs are mooued when the Chest remaineth immouable: which thing Experience also confirmeth. For if the Chest be opened so as the aer may get in by the wound, the Lungs become immouable, because the aer being gotten

are neuer
weary.

into the void and empty space taketh away the necessity of the motion of the Lungs which is to auoid vacuity as we haue saide: but if the Chest be sound, it is of necessity that it beeing distended the Lungs also should bee dilated for auoyding of that vacuity. And whereas *Auerboes* objecteth that there is no violent motion perpetuall, and yet the motion of the lungs should be violent if it should follow the motion of the Chest. I answer, that the inference is very absurd, for euery motion is not violent which is mooued after anothers motion, for by that reason the bones also should bee mooued with a violent motion. But why are not the Lungs wearied with their perpetuall motion? I answer, because they are almost insensible.

QUEST. XII.

what kinde of motion the Cough is, and whether any part of the
drinke fall into the Lungs.

What parts
are causes of
coughing.

THat the Cough proceedeth from the affection of almost all the parts of the Chest, as the *Pleura*, the *Mediastinum*, the Lungs with their vessels, the midriffe, and sometimes of the *Intercostall* muscles also, it is more then manifest; For in both the kindes of *Pleurisies*, the true and the bastard, the *Peripneumonia* or inflammation of the Lungs; the *Asthma* or difficulty of breathing, the vicer of the Lungs called *Phoe*, the Drop-sie wherein the Midriffe is pressed vpward: in all these I say the Patient is troubled with a continuall Cough. But now to what faculty we should referre this coughing that is a great controuersie. It may be thought it is Animall and voluntary, because the Cough is nothing else but a strong efflation or breathing forth. Now this efflation is done by the helpe of all the muscles which contract the Chest.

That the cough
is from the A-
nimall faculty.

Galen also in his second Booke *de causis symptomatum* speaking of sneezing coughing and vomiting, concludeth that vomiting is a symptome of the naturall faculty, and coughing of the Animall. Others there bee which thinke it to bee an action of the naturall faculty, because it is a concussive motion and is done by the endeouour of Nature, to exclude that which is offensive vnto her; now all Concussive motions are Naturall. For all the parts of the body of their owne naturall constitution haue euery one their owne *Concussions* when they are shaken for the auoyding of any thing which offends them: such is the concussion of the braine in sternutation or sneezing; of the stomacke in the hiccock, of the bladder in auoyding the stone, of the whole habite of the body and the fleshy membrane in a rigor or shaking fit, and finally of the Chest in coughing. Moreouer sometimes we cough against our will, neither can we alwaies when we will forbear it. Both these opinions may be reconciled, if (as we saide earst in respiration so here in coughing) that it is a mixt action of an Animall and a Naturall.

That it is from
the naturall
faculty.

The reconcil-
iation of these
two opinions.

The motion is Animall because it is done by the helpe of muscles, but the cause moouing the motion is Naturall; for a cough is not raised without the endeouor of the expelling faculty. But another question may be asked here, whether the cough be a disease or an ordinary worke of Nature? *Galen* in his second Booke *de symptomatum causis*, and in his fift *de locis affectis* seemeth to determine diuersly; sometimes that it is a worke of Nature: and sometimes againe as in his Booke of *Trembling and Palpitation*, that it is against Nature: but we may well reconcile *Galen* with himselfe if we say, that in respect of the faculty whereby we cough it is a Naturall affection; for the beginning of the motion is from Nature, that is from the expelling faculty; but in respect of the cause which mooueth the faculty as the rheume, the bearing vp of the midriffe or such like, it is against Nature and a very disease; but ouer this cause the Naturall faculty hath a kind of power or command which it sheweth in laboring thus to auoide it.

Whether to
cough be a
disease or no.

Galen reconcil-
ed to himselfe

Whether the
drinke go into
the lungs.

To conclude both this Chapter and all our discourse of the vitall parts, it is a question whether the drinke we drinke goe into the Lungs or no. *Hippocrates* sayeth in his Booke *de corde* some part of it goeth that way, because if you giue a Swine a drinke coloured with vermilion or any such like thing and presently cut the throat, you shall perceiue the weazon colored with the drinke, which is a certaine argument and demonstratiue; also in the same place he thinketh that the water which is found in the *heart purse* is a portion of our drinke: againe Physitians in the fretting or exulceration of the weazon, and diseases of the Chest do

appoynt

appoynt the Patient to ly long vpon his backe and leasurely to licke downe their medicines, that so some of them may fall downe into the Lungs.

Another demonstration may be that the arteries haue more whey or vrine in them then the veines; whence should this whey come? but that a part of the drinke and more liquid nourishment doth slippe downe by the weazon into the Lungs and so into the arteries, and from them by the emulgent arteries into the kidneyes to be auoided by the bladder: for I see no reason why the emulgent arteries should haue beene made so large, vnlesse it were for the expulsion of this excrement. *Aristotle* amongst all the Philosophers is against this. *Hippocrates* in his fourth Booke *de morbis* laboureth might and maine against it, yeelding diuers reasons why it cannot be: but we must vnderstand that *Hippocrates* laboureth to proue that all the drinke goeth not into the Lungs, he confesseth that some slipperh by. And thus *Galen* in his eight Booke *de placitis Hippocratis & Platonis* reconcileth *Hippocra.* to himselfe; namely, that some of the drinke falleth insensibly downe along the weazon, the rest passeth ouer the *Epiglotis* into the stomack: but if neuer so little a crum of solid meate get into the weazon, it bringeth danger of suffocation. So *Anacreon* the Poet was suffocated with a Grape-stone. And *Fabius* the Senator is said to haue beene strangled with a haire which got into his weazon in supping of a draught of Milke. *Alexander Benedictus* writeth that a mother at *Brussels* thrust a pill downe her childe's throate with her finger, vpon which it presently dyed.

Why the emulgent arteries are so large.

Exempl of such as haue beene choked with crums or such like.

And thus much shall bee sufficient to haue beene saide concerning the vitall parts belonging to the middle Region called the Chest, with all the Controuersies and subtleties of Nature thereto appertaining. It followeth now that we should ascend vnto the Throne of the soule, the Tower of the body, which is the Head.

Conclusion of the discourse of the vitall parts.

The end of the Sixt Booke and the Controuersies thereunto belonging.

Of the Third and vpper-most Venter called
the Head, wherein are described the
Animall Organes.

THE SEVENTH BOOKE.

The Præface.

Wherein is contained the summe of the first Eight Bookes.

As a Traueller that desireth to make profit of his paine, when hee hath passed one Citie, before hee enter into another will recount with himselfe his principall obseruations, especially when the recognition of the former may stand him in steade for his better vnderstanding in that to which hee bendeth his course: so I thinke it not amisse hauing passed through so great variety of parts in the body of Man, before I enter into the Third, to call vnto your remembrance (not all the particulars before rehearsed, for that would be irkesome to vs both Gentle Reader) but the Principall, as well to refresh thy memory, as also to make a more easie passage vnto that which followeth.

Man who is the subiect of our whole Discourse, consisteth of a Soule and a Body. The Soule is the Lady and Mistresse, the Soueraigne and Commander. The Body is a most perfect Organ or Instrument of the reasonable Soule, consisting as *Hippocra.* well saith (though obscurely) of Fire and Water.

Why the body
is made of many
organs.

For the Soule, albeit when shee is free from the prison of the Body can see without an Eye, heare without an Eare, and by her owne simple acte discourse without the help of spirits; yet so long as she is immured within these wals of clay she cannot contemplate the Ideas of Externall things without an Externall medium; and therefore Nature (by which I vnderstand the wisdom of the eternall Creator) framed the body of many Organically parts whereby and wherein the Soule might exercise her Diuine administrations, produce and exhibit the powers and efficacies of her manifold Faculties. For the Body indeed is but a dead trunke till the Soule arriue into it, and quickneth it vnto the performance of perfect actions of life.

But because the Soule is of all Formes the most excellent as being created immediately partaker of immortality, Nature in emulation of the diuine *Numen* hath striven to make her habitation also immortall, which although the destiny of the matter did gaine say, yet shee hath brought to so admirable a perfection that it is worthily called *θαύμα θαυμάσιον*; the wonder of Wonders, the Miracle of Nature, and a Little world.

Why the spirit
was created.

Whereas therefore there was no proportion or correspondencie betweene mortality and immortality, betweene the Soule and the Body; Nature with wonderfull skil, out of the principall part of the seede did extract and separate a spirit which lay lurking in the power of the Matter, a spirit I say of a Middle nature betweene Heauen and Earth, by whose mediation as by a strong band the diuinity of the soule might be married to the humanitie of the body. This instrument of Nature we call Fire, which moueth and illustrateth the whole

whole packe of the members, and moderateth all and singular actions of life, of which also it is the next and most immediate cause or instrument.

But because the nature of Fire is such that it hath in it much forme and but a little matter, neither can diffuse the beames of his light vnlesse it be receiued into some substance wherein his power may be vnited; therefore it was necessary there should be another Principle not so subtile, wherein this aetheriall body might expatiate & disport it selfe according to the diuersity of his functions and that without danger of expence. Such a Principle is the mutual confluence of the seeds of both parēts, out of whose slimy matter the *Plastical* or formative faculty of the womb stirred vp by the vigor of heate diduceth and distinguisheth the confounded power of the parts into their proper actions, not without a discerning Iudgement and naturall kinde of discourse. This masse of seede irrigated with the power of the whole body according to *Hippocrates* I call *Water*; not onely because this Element doth delineate nourish and make fruitfull, but also because the future siccity and hardnesse of the spermatie parts stood in neede of a moist and viscid matter whereby those things which otherwise could hardly be sammed together might receiue their conglutination, that so of many dissimilar particles, one continued frame might arise.

The second principle.

This frame thus coagmentated and distinguished for the seruice of the soule, we haue in the beginning of this worke compared to the whole world or vniuerse, and that not without good ground. For as of the world there are three parts, the Sublunary which is the basest, the Cœlestiall wherein there are many glorious bodies, and the highest Heauen which is the proper seate of the Diety. So in the body of man there are three Regions. The lower Belly which was framed for the nourishment of the *Indiuidium* and propagation of mankinde. The middle Region of the Chest, wherein the Heart of man the sunne of this *Microcosme* perpetually moueth and poureth out of his bosome as out of a springing fountaine the diuine Nectar of life into the whole body; and the vpper Region or the Head wherein the soule hath her Residence of estate, guarded by the Sences and assisted by the Intellectual faculties, at whose disposition all the inferior parts are employed.

How the body is like the world.

In the lower Region Nature hath placed two parts more excellent then the rest, whereof one endeouoreth and attendeth the conseruation of the *Indiuidium*, the other of the Species or kinde. The first is the Liuer which some haue said is the first of all the bowels, both in respect of his originall and of his nature. It is seated in the right *Hypochondrium* vnder the midriffe. The figure of it (if you except his fissure) is continuall, but vnderneath vnequall and hollow, aboue smooth and gibbous. In a man this bowell is proportionably greater then in any other creature, and greatest of all in such as are giuen to their bellies. The proper *parenchyma* or flesh of this Liuer, which is most like to congealed and clodded blood, by a proper and inbred power giueth the forme, temper and colour of blood to the Chylus conected in the stomacke, deriued into the guts, prepared in the meseraicke veines and branches of the gate-veine, by which also it is transported to the hollow part of the Liuer, there as we saide wrought and perfected, and so conueyed by the same rootes of the gate-veine, and thence exonerated into that which is called the *Cava* or hollow-veine, by whose trunks and boughes it floweth into the whole body. The temperament of this Liuer is hot and moist; for the moderation of which heate and conseruation of the spirits therein contained it receiueth certaine small Arteries which attaine but onely vnto the cavity thereof. It is inuested round with a thinne coate wherein two small Nerves belonging to the sixth coniugation of the braine are diuersly dispersed.

The lower Region.

The Liuer.

We say moreover; that this same Liuer is the shop or work-house of the venall blood and the originall of the veines; in whose thrummed rootes the more aery portion of the Aliment is conuerted by the in-bred and naturall faculty of the Liuer into a vaporous blood, which becommeth a naturall, thicke and cloudy spirit, the first of all the rest and their proper nourishment: which spirit is the vehicle of the Naturall faculty, and serueth beside to helpe to transport the thicker part of the blood through the veines into the whole bodie; where it needeth but a little ayer and therefore is refreshed and preserued only by Transpiration made by Anastomoses or inoculations of the Arteries with the veines in their extremities or determinations. This Naturall faculty (wee before mentioned) is diuided into three faculties, the Generatiue, the Alteratiue and the Increasing faculty. Of the Generatiue we shall speake by and by. The action of the Alteratiue faculty is Nutrition which hath many handmaidens attending her, Attraction, Expulsion, Retention, and Concoction. The action of the Increasing Faculty we call Accretion, that is, when the whole body

The Naturall faculty.

encrea-

encreaseth in all his dimensions. Finally, we say that concupiscence as it is a distinct Faculty from Reason and Rage, ruleth and beareth sway in the Liver as in her proper Tribunall, and is distinguished into *Libidinem & Cupediam, Lust and Longing*.

The parts of
Generation.

But because in all her workes Nature ever intendeth immortality, which by reason of the importune quarell and contention of contraries she could not attaine in the *individuum* or particular, she devised a cunning stratageme to delude the necessity of Destiny, and by an appetite vnto the propagation of the kinde, hath sowed the seedes of eternity in the nature of Man, For the accomplishing of which propagation shee hath ordained conuenient instruments in both sexes, which are for the most part alike, but that the instruments of the Male are outward, those of the Female for want of Naturall heate to driue them forth are deteyned within. The Chiefe of these are the Testicles, two Glandulous bodies of an ouall Figure which in men hang out of the *Abdomen* and are inuested with foure Coats, whereof two are common, the *scrotum* or Cod a thin and rugous skinne, and the *Dartos* which hath his originall from the fleshy Panicle. The other two are Proper, the former is called *Erytroides*, and the latter *Epididymis*. The temperament of these Testicles is hot and moyst, and they haue a very great consent with the vpper parts especially with the Middle Region, as also hath the wombe. The manner of the Operation of the Testicles is thus.

The Testicles.

The matter of the seede, together with the spirits carrying in them the forme and impression or character of all the particular parts and their formative Faculty, falleth from the whole body and is receiued by the Spermatice Vessels, in whose Labyrinths by an irradiation from the Testicles it is whitened. After it is so prepared it is conueighed to the *Epididymis* thorough whose insensible passages it sweateth into the spongy and friable substance of the Testicles themselves, where hauing attained the forme and perfection of seede it is deliuered ouer by the ejaculatory or rather the Leading-vessels to the *Parastata*, and from them transcolated to the *Prostata*, which reserue the seede being now turgid and full of spirits for the necessary vses of Nature. Hence it followeth that the power which is called *seede-making*, that is, the *seede-making* Faculty, or the Faculty of generation, is from the Testicles immediately, by which Faculty, the parts being stirred vp do poure out of themselves the matter of the seede when *Venus* doth so require. This Faculty is the author in men of Virility and in women of Muliebrity and breedeth in all creatures that *per se* by which the heate being blowne vp is the cause *τῆς ἐκβολῆς*, so that the blood being heated and attenuated distendeth the Veines, and the body or bulke of that part groweth turgid and impatient of his place, which the Grecians call *ἐκβολή*. And thus much of the Lower Region.

The Middle
Region.

In the Middle Region there are many parts of great worth, but the excellencie of the Heart dimmeth the light of the rest, which are all to it but seruants and attendants.

The Heart.

The heart therefore is called *καρδία ἀπὸ τῆς καρδίας*, which signifies *to beate* because it is perpetually moued from the ingate to the outgate of life.

This is a Pyramidal Bowell whose *Basis* is in the middle of the Chest, the *muero* or point reacheth toward the left side. The magnitude but smal that the motion might be more free and nimble, the flesh very fast and exceeding hot intertexted or woven with all three kinds of Fibres but those made of his owne flesh, and nourished with blood which it receiueh from two branches of the Coronary Veine.

On the out-side it hath a great quantity of fat and swimmeth in a waterish Lye without acrimonie, which is conteyned in the *Pericardium* wherewith as with a purse the Heart is encompassed.

On the inside it is distinguished by an intermediate *partition* into two Ventracles. The right is lesse noble then the left and framed most what for the vse of the Lungs. It receiueh a great quantity of blood from the yawning mouth of the Hollow-veine, and after it is prepared, returneth the same blood againe through the Arteriall veine into all the corners of the Lungs. This right ventricle hath annexed to it the greater eare, and sixe Valves are inserted into the Orifices of his vessels. The left Ventricle which is also the most noble hath a thicker wall then the right, because it is the shop of thin blood and vitall spirits. Out of this Ventricle do two vessels issue, the first called the Venall artery which receyueth the ayer prepared by the Lungs, and for retribution returneth vnto them vitall blood and spirits; at which artery the left deafe eare is situated, and in whose orifice there stande two Valves bending from without inward. The other vessell of the left Ventricle is the *Aorta*

or great Artery which distributeth vnto the whole body vitall blood and spirits, or (according as the opinion of some is) it draweth the better part of the Chylus by the Meseraicke Arteries into the bosome of the left ventricle for the generation of Arteriall blood, and at his mouth do grow three Valves opening inward. Wee say further that the Heart is the habitation of the vitall Facultie, which by the helpe of Pulsation and Respiration begetteth Vitall spirits of Ayer and Blood mixed in the left Ventricle. And this Facultie although it bee Virall yet is it not the *Life* it selfe, and differeth from the Facultie of Pulsation both in the functions and in the extent and latitude of the subiect. The Facultie of Pulsation is Naturall to the heart, as proceeding and depending vpon the vitall facultie. For it is not moued *αποαισθητικῶς* or voluntarily as is the Animall Facultie, but onely obeyeth the command of the necessitie of Nature.

The Vitall facultie.

From the foresaid facultie of Pulsation do proceede two motions, the *Diastole* and the *Systole*, betweene which there is a double Rest. These motions in the Heart and Arteries are the same and at the same time, but so, that the cause of the motion is supplied from the Heart vnto the Arteries as from a principle both moued and mouing.

Finally, to come vnto that which we are now in hand withall. In the vpper region we meete with the braine compassed with the strong bartlements of the scull, adorned with the Face as with a beautifull Frontispice, wherein the Soule inhabiteth, not onely in essence and power as it is in the rest of the body, but in her magnificence and throne of state. This Braine is the most noble part of the whole body and framed with such curiosity, so many Labyrinths and Meanders are therein, that euen a good wit may easily bee at losse when it is trained away with so diuers sents in an argument so boundless and vaste. Notwithstanding we will as briefly and succinctly as we can giue you a viewe of the Fabricke and Nature thereof, referring the Reader for better satisfaction to be ensuing discourse, wherein we hope to giue euen him that is curious some contentment.

The vpper Region.

The substance therefore of the Braine is medullous or marrowy, but of a proper marrow not like that of other parts; framed out of the purest part of the seed and the spirits. It is mouable and that with a naturall motion which is double, one proper to it self, another comming from without. It is full of sence, but that sence is operative or actiue not passiue. For the behoofe of this Braine was the head framed, nor the head alone but also the whole body, it selfe being ordained for the generation of animal spirits and for the exhibiting of the functions of the inward senses and the principall faculties: in this braine we are to consider first his parts then his faculties.

The Braine.

The Braine therefore occupieth the whole cavity of the skull, and by the *Dura mater* or hard Membrane is diuided into a fore-part and a backe-part. The fore-part which by reason of the magnitude retaineth the name of the whole and is properly called the Braine, is againe subdiuided by a body or duplicated membrane resembling a mowers sythe, into a right side and a left, both which sides are againe continued by the interposition or mediation of a callous body. This callous body descending a litle downward appeareth to be excauated or hollowd into two large ventricles much resembling the forme of a mans care, through which cauities a thrumbe of crisped vessels called *Plexus choroides* doth run, wherein the animall spirits receiue their preparation; and out of these Ventricles doe yssue two swelling Pappes which are commonly called the Organes of smelling and do determine at the spongy bone about the top of the nose.

These two Ventricles are disseuered by a fine and thin body called *Speculum lucidum*, or the *Bright Glasse*, vnto which adioyneth the Arch of the Braine called *Corpus Cameratum*, which is supported by three Columnes which like *Atlas* do sustaine the weight of the Braine, so that the third ventricle which lieth vnder them is not obliterated. This middle ventricle which is a common cavity of the two vpper, occupieth the very center of the braine and runneth out with a double passage. The first descendeth to the Basis of the Braine where the originall of the Nerves is most manifest, and the extremity thereof endeth in a portion of the *Pia mater* or thin membrane very like vnto a Tunnell, through which Tunnell the flegmaticke excrement of the Braine is transcolated into the pituitary glandule thereunder disposed; and so thorough the holes of the wedge-bone distilleth into the Palate of the mouth.

The other passage of the third ventricle which is larger then the former is directed vnto the fourth ventricle where the Glandule or kernell called *corāptor* is seated, at each side of which do adioyne the *Buttocks* of the Braine, and vnder them the *Testicles* appeare, which seuer the passage of the Animall spirit out of this into the fourth Ventricle. Finally, the fourth ventricle

The Animall
Faculty.

succeedeth, which is the least and most solid of all the rest, and wherein say some, the Animall spirit receiveth his utmost perfection, and therefore it is made in the Cerebellum, that is, the backward or After-braine, which for this very reason was framed of a harder consistence then the former. And so much of the parts of the braine. Now for the faculties; we determine that the Braine is the Pallace of the Rationall Soule, which Soule vsing for her instrument the temper and conformation of the Braine, according to the diversity of her functions bringeth forth mixt actions by the mediation of the Animall spirit. These very actions produced according to the variety of the temperament and *medium*, into diuers acts of Ratiocination, Imagination and Memory (as the Soule is best pleased to worke) we call faculties; which are seated and established together and promiscuously in one and the same place.

Again; we say that this Braine as it is the beginning of the inward, so is it also of the outward senses, from which each of them receiuing their proper vessels or passages together with their Faculty do suffer the incursions of Species or Images resorting vnto them according to the diversity of the Organe. The eye receiveth the visible formes, the eare the audible, the nose such as cast an odour from them; and so of the rest. All these individuall formes received by the senses, are by them resigned vp in token of fealty to the Common sense or priuy-chamber of the Soule from whence they receyued their faculties; and then out of those formes the Soule gathering phantasmes or notions doth eyther lay them vp in the memory, or work vpon them by discourse of Reason. Finally, we attribute to the Braine the faculties of sense or motion, which faculties together with the Animall spirit differing in forme and kinde from the vitall, and prepared concocted and perfected in his ventricles and substance, he doth continually and without intermission transmitt through the same nerues into the whole body to supply the expence of the foresaide spirits, which is made either by action or by passion.

And thus haue wee runne through not onely the two lower Regions to refresh our memories, but also the vpper, wherein the Reader may haue such a taste of that which followeth, as may haply make him sauiour it the better when he commeth thereto. And so wee proceede to our businesse.

CHAP. I.

Of the Names, Scituation, Forme and Parts of the Head.

AVING hitherto as exactly as we could and with great leasure made our progresse through the two lower Regions Naturall and Vitall: It is now time wee should ascend into the third venter, the seate and very residence of the Soule, the sacred Pallace or Tower of Pallas, and there suruay her Royall Court, her Guard of outward Senices, her Councillors of State and all their equipage.

The Names of
the head.

This Region therefore is by the *Grecians* called κεφαλή, κέριον and κέριον. *Appians* Interpreter holds it was called κεφαλή, of a word which signifieth to grow dry, because being of a bony substance it must needs be dry. *Apollidorus* derives it from the word καλύπτω to hide or couer, because it is the courring of the braine. Others because there κείται τὰ φῶς the lights are placed. Others ἀπὸ τῆς κενοῦρας, from the Cavity or hollownes of it. The *Latins* call it *Caput*, because from hence the senses do *Capere initium* take their beginning.

A strict signi-
fication
Celsus descrip-
tion of the
Head.

There is a double acception of the word *Caput* among Physitions, one strickt and presse, another large and ample. In the strickt signification it is vsed by *Celsus* our of *Hippocrates* Booke of the wounds of the head and thus described. The Head is the Mansion and skonce of the Braine, whose skull is made of two tables, betweene which is a marrowey substance called *Diplois*, inuironed with Caruncles and small veines, ouer which is spread the Membrane called *Pericranium*; which Membrane is couered againe with the hairy scalpe; but vnder the skull lyeth the Membrane called *Dura mater*. And in this signification the ancients called it ἀρτήρ, the Vessell of the braine; wee also in our common speech call it the

Skonce.

Skonce.

The large sig-
nification.

But in the large and ample signification, vnder the name of the head we vnderstand all that is circumscribed within the first racke-bone of the Necke and the top of the Crowne. Wee wil intreate of it in this large signification: wherein therefore we are to consider of the forme, the Scituation, the Magnitude, the Frame and Structure, the Motion and the Particular parts thereof.

First

First, therefore the head was made round and that for diuers reasons. Inprimis: That it might be of greater receipt & capacity, because it was to receiue the vast & huge bulk of the braines. For the braines of a man are foure times as big as of an Oxe: now of all figures the round figure is of most capacity, witnesse the world it selfe.

The forme.

Secondly, the head was made round *ad suauitatem*, that it might be lesse subiect to outward iniuries nor so easily wounded. For this figure as it is most capacious, so is it the strongest, because it hath no asperity whereupon a blow might fasten, but is euery where a like smooth, hauing no point whence the dissolution of it should commence.

Why round.

Thirdly, the head is round for his better motion, that it might bee speedily and easily turned to euery side. The *Platonists* thinke that the head was therefore made round, because it is the seate and habitation of the Soule. For the Soule is infused into vs out of Heauen which is round. Adde heereto that the most Noble member deserued the most Noble figure.

Notwithstanding though the figure of the head bee round, yet is it not exquisitely and to a haire globous, but somewhat long, swelling out with two tops like promontories, which therefore they call heads of land; it is also pressed on the sides. Long it was to containe the braine and the Cerebellum; swelling out before because of the mammillary processes which are the Organes of smelling, and behind to admit the originall of the marrow of the backe.

Why come referred.

It is pressed on the sides, but more forward: first because the proceffe of the backe called *Dorsalis*, is much thicker then that ordained for the outlet of the Nerves of the face. Secondly, because in the forepart there was to be a bosome or hollownesse, into which the aer was plentifully to passe, that is, the mouth. Thirdly, that the eyes rowling on eyther side, might not haue their prospect hindred by the bones of the Temples, which would haue bene if the skul in that place had bene more embowed. Lastly, that the head might stand equally ballanced; for seeing the forepart hath his waight increased by the lawes, the head would haue waighed too much forward if the back-part had not bene more embowed and runne out as it were into a knowle, which therefore with little alteration in the word and lesse in the sence we call the *Nowle* of the head.

More on the forepart.

But descanting thus about the figure of the head, it must bee vnderstood that wee meane a head Naturally disposed; for otherwise of vnnaturall formes, some are perfectly round, others do rise vp in the toppe like a ridge almost of a house, bearing little bredth in the Crowne. The round head they call in Greeke *κρανιον* because it hath no *προβολη* or ietty eyther in the fore-head or in the nowle. The sharpe or turbinated head is called *ραξος* or as *Athenaus* hath it *ραξος*, because to them that behold it, it seemeth somewhat sharpe like a Sugar-loafe. Such a Head had *Thersites* in *Homer* much like those moulded Cups among the Græcians which were called *ραξιδες*. *Eustathius* rather thinketh it is called *ραξος* quasi *ραξος* of *ραξ* which signifies flame, because flame endeth in a sharpe Cone or spire. But of the formes a little more heereafter when we will also exhibite the pictures both of the Naturall and of the vnnaturall formes.

Naturall heads.

Vnnaturall.

Thersites in Homer.

The magnitude of the head is diuers in diuers creatures, yet greater in man then in any other, because his braines are of a bigger bulke. A little head is alwayes faulty, because it argueth both the impotency and weakenesse of the forming Faculty, and also the want of spermatie matter. Whence it is that Physiognomers say, that a little head betokeneth a sudden and rash wit, because in such there is want of spirits, which being pent vp in a narrow roome, are heated about measure, and beside haue no space to moue themselves in.

The magnitude. A little head.

A great head, if other things be equall, that is, if there bee an equall proportion of all the bones is alwayes laudable. Whence *Hippocrates* in the sixth Booke of his *Epidemion*, sayth, that wee must esteeme and measure the Nature of the bones according to the magnitude of the Head: not that the bones doe arise from the Head, but because all the bones should proportionably answere to those to which they are articulated or ioyned. For example, The bones of the arme to the shoulder bones, the hippes to the holy-bone, the holy-bone to the racke-bone, the racks to the marrow of the backe, the marrow to the braine, the braine to the skull.

A great head.

Hippocrates expounded.

But *Aristotle* in his Problemes saith that a man is the wisest creature, because hee hath a little and a short Head. Wee must vnderstand that by *Paruity* hee meaneth the thinnesse of the bones and the flesh, not that the inward cavity of the skull is little in respect of other creatures.

Aristotle expounded.

The situation

Galen.

Auerroes.

Why the brain
is set highest.

The Head is situated in the highest place, because say the *Platonists* it behoued that the intelligible Faculty of the Soule, as the Queene and Princeesse of the rest should sit in an elevated Tribunall, that the *Irascible* and *Concupiscible* Faculties as handmaydes should rest at her feet, bee seruiceable vnto her and obey her commands. *Galen* doeth not say in his eight Booke of the *Vse of parts* (though *Auerroes* would father it and fasten it vpon him) that the Head was made for the Eyes; (for it was made onely for the Braine) but he saith indeed that it was lifted vp into the highest place because of the Eyes. For the Eyes being ordained as scout-watches, to looke out for vs Night and Day, it was requisite that their station should bee in the highest place; but because the sight stood in neede of the softest sinew and the shortest, least his soft body if it had beene any thing lengthned might haue beene in danger of breaking: therefore it was necessary that the Braine which is the originall of sinewes should be placed neere the Eyes: neither doth this scite of the braine auayle the Eyes onely, but also all the senses, for the smell better apprehendeth an ascending vapour, and the voice is better heard from above.

The parts of
the head and
their names.The parts of
the scalp.Hippocrates.
Aristotle.

Galen.

Another diu-
sion of the
parts.
Contayning.

Contayned.

The Head is diuided into two parts, the one is hayry the other without hayre: the hayry part is called *τριχωτός*, *Calua* the scalp; that which is without haire is called *πρόσωπον*, *Facies* the Face. The scalpe from the cauity and roundnes of it is called by *Aristotle* in the 1. Booke of his History of creatures and the 7. Section, and by *Pollux* *σκαρίον*. This comprehendeth all the vpper part, backward as farre as the haire groweth, forward to the forehead: it hath three parts. The forepart reacheth from the forehead to the coronal suture or crowny seame and taketh vp almost halfe of the head; it is called *βρέγμα ἀπὸ τοῦ βρέχεν* which signifieth to water, because it is the softest and the moistest, *Sinciput* also of the Latins, as if it were *summu caput* the top of the head, although there be a higher place.

The backpart of the scalp reacheth from the Lambdall suture to the first rack-bone of the necke. *Hippocrates* in his Booke de *vulneribus capitis*, calleth it *ωτίς*. *Aristotle* *πρὸς ἀνὰ τὸ ἰσθμὸς τοῦ νυμφῶδος εἶναι*, because it is fibrous and neruous, for many tendons reach vnto it; beside almost all the nerues arise from about that part, in Latin *Occiput* or *Occipitum* as *Plantus* hath it; we call it the nowle. The middle part of the scalpe betweene these is gibbous or round called in Greeke *κορυφή* of *κρύπτω* to hide as it were *κρυφή*, because that part of the head is especially couered with haire.

Galen in the eleuenth Booke of the *Vse of parts* and the 14. Chapter, calleth it *Aruum pilorum* the Field of haire: the Latins call it *Vertex*, because in that place the haire runne round in a ring as waters doe in a whirle-pool. Finally, the sides of the scalp betwixt the Eyes, the Eares and the Necke are called *κόρυθαί, παρά τὸ κρυτεῖν περὶ τὴν ἀσπίδα*, saith *Aristotle* in his first Booke of his History and the eleuenth Chapter, because the pulse is there very manifest; the Latins call them *Tempora*, because their gray hayres and sunken flesh bewray the age of a man.

Againe, the parts of the scalp are containing and contayned. The containing parts are some of them Common some Proper. The Common, are the *Cuticle* or scarfe skinn, the true skinn bearing a wood or bush of hayre, the Fat and the Flethy pannicle. The Proper containing parts are either externall or internall. The externall are two Membranes, *Pericranium* and *Periostium*, certain muscles and the bones of the head. The proper inward conteyning parts are two mothers called *Meninges*, *dura* and *pia*, which encompass both the skull and the braine.

The parts contayned are the braine and the *Cerebellum* or after-braine, from which ariseth the marrow, which when it is gotten out of the skull is properly called the marrow of the back, or pith of the spine, from which doe arise many nerues as well before it issue out of the skull as after. Of these we will first entreat, and then after of the part without haire or the face in the Booke following.

CHAP. II.

Of the common contayning parts of the Head.

Common
parts.

THe common contayning parts of the head are 5. the haire, the cuticle, the skin, the fat, and the fleshy pannicle, of all which we haue spoken heretofore at large; yet because in euery one of these there is some difference from the same parts in other places of the body we must a little here insist vpon them, and first of the haire.

Albeit

Albeit therefore the haire is generally more or lesse all ouer the body as before is said, yet about all places the head is adorned with the greatest aboumdance of them. The haire of the head are the longest of the whole body, because saith *Aristotle* in his first Booke *de Generatione Animalium* and the third Section, the braine affoordeth toward their nourishment a large supply of humor, or vaporous moysture whether you will, which also is most clammy and glutinous. For the braine is the greatest of all the glandulous bodies. They are also in the head stiffest, because the skinn of the head is the thickest, yet is it rare and full of open pores, so saith *Galen* in his ninth Booke *de vsu partium* and the first Chapter. In the head Nature hath opened conspicuous and visible waies for the vaporous and smoky or sooty excrements, for the head is set vpon the body as a rooffe vpon a warme house, so that vnto it doe arise all the fuliginous and vaporous excrements from the subiected parts. The haire of the head are called in Latine *Capilli*, as it were *Capitis pili*, by *Pollux* and *Eschylus* *κρίνα* to cutte. In men they are called *κρίνα*, *Casaries*, because they are often mowed; in women *κρόμη* of *κρόμη* to dresse with diligence, from whence haply wee haue our word to combe, or rather from the Latin word *Coma*, whose signification is al one with the former. In women they are diuided by a line, which separation the Greeks call *λυσισμα* the Latins *discrimen* and *equamentum*, in English ewecall it the shed of the haire.

The skinn of a man although in comparison of other creatures it is most thinne; yet if you compare the skinn of the head with that of the chest or the lower belly it is very thick as also is the cuticle. And therefore *Columbus* insulteth ouer *Aristotle* for saying that the skinn of the head is very thinne. The place is in the 3. Booke of his history of Creatures, and 11. Section, where he doth not say that the skinn of the head is very thinne, (for in the fifth Booke *de Generatione Animalium* and the 3. Chapter, hee calleth the skinn of the head *παχυτάτος*, that is, very crasse and thicke) but he saith (and that truly) that the skinn of a man in respect of his magnitude is very thin.

Well, the skinn of the head as it is the thickest, so (saith *Galen* in his second Booke *de Temperamentis* and the 5. Chapter) it is so much drier then the skinn of the rest of the body by how much it is harder; yet is it rare saith *Aristotle* in the place next about named, that the sooty excrements might be auoided for the generation of haire as before is said. It hath vessels running in it, Veines from the outward branch of the externall iugulars, which creeping on both sides are vnited in the forehead, and are sometimes opened in grievous paines of the head, and these veines running vnder the drie and hairie skinn carrie blood vnto it for nourishment. Arteries it hath also from the outward branch of the *Carotides* deriued to the rootes of the eares and to the temples especially, which bring Vitall spirits vpward from the heart.

It receiueh also certaine ends of Nerues reflected vpward from the 1. and 2. coniugation of the Neck to giue it sense. I said ends of Nerues, for so saith *Galen* in his 16. Booke *de vsu partium* and the 2. Chapter. The skinn hath not a proper and definite Nerue belonging vnto it as euery Muscle hath his Nerue disseminated in or about his body; but there attaine vnto it certaine Fibres from the subiected parts which connect or knit it to those parts, & also affoord sense vnto it. The sense of this skinn of the head is not fine and exquisite as in the chest or the Lower belly. *Aristotle* in the 3. Booke of his History and the 11. Chapter saith, it hath no sense at all, and rendreth at reason because it cleaueth to the bone without any interposition of Flesh. But *Galen* disproueth this opinion in his 16. Booke of the vse of parts, and the 2. Chapter. It may be *Aristotle* meant the Cuticle and not the true skinn. Or excuse him as *Archangelus* dooth, who saith that he meant it of the true skin, but as it is a similar part distinct from a Nerue, for indeed onely the Nerues haue sense. *Bauhine* and *Laurentius* giue another reason why the skinn of the Head is lesse sensible, because (say they) in the Head the skinn adhereth but to a Musculous or fleshy Membrane, whereas in other parts it cleaueth to a neruous Membrane.

The vse of the skin of the head is to compasse the scull and be a couering vnto it.

There is no Fatte at all (saith *Platerus*) vnder the skinn of the Head, and he giueth his reasons, first because there is no vse of it, for the small vessels vnder the hairy Scalpe are placed in sufficient safety, there needed therefore no Fat at all to secure them. Secondly, because there had beene an abuse of it. For in the Infant the Head is proportionably to the other parts exceeding great, but if it had any Fat about it, it would haue beene a great *Remora* or impediment in the birth. But *Vesalius* in his 7. Booke and the 18. Chapter saith, that a man may easily with his hands diuide the skin with the Fat, and the fleshy Membrane from the Scull. And

The vse.

The fat.

Platerus.

Columbus saith, that beside the *Yard* and the *Codde* there is no part but a man may finde *Fat* in it. The truth is, that in the fore-head there is none at all, for because in the fore-head the skin is moued at our disposition it would haue been a hinderance to his motion, for that in this place the skin is vnited to a Musculous substance, but in and about the *Occipitium* or nowle of the head there is some *Fat* to be found.

The fleshy
membrane.

Falopius.

The fleshy Membrane spread vnder the skin cleaueth close vnto it in the fore-head, because there is no *Fat* to separate them, and there this Membrane is very thick. It also sometimes runneth like a tendon from the Muscles of the fore-head to the Muscles of the nowle and the eares, insomuch that *Falopius* warneth vs to take heed least we mistake if for the *Pericranium*, and the *Pericranium* for the *Periostium*. And thus much for the common inuesting parts of the Head, how they differ from the same parts in other places of the Body.

CHAP. III.

Of the *Pericranium*, *Periostium*, and the Muscles about the Head.

Pericranium.

Falopius.

His originall:

Progresse.

The Membrane which lyeth next vnder the fleshy Pannicle is called *περικράνιον*, because it compasseth the whole scull on the out-side. The Arabians call it, *Almocat* and *Almocatin*. *Laurentius* would haue it called *Periostium*. And *Falopius* in his Institutions and in his Booke *de Ossibus* and the 19. Chapter saith, that this Membrane is common to all the bones about the scull and called *Pericranium*, but by his common name *Periostion*. It is scituated betwixt the fleshy Panicle and the *Periostium*, to both which it is tyed by certaine Fibres. Soft it is and thin, but thight and solid saith *Laurentius*, and of exquisite sense. It ariseth from certaine processes of the *Dura Meninx* like thin Membranes or rather Ligaments (for they haue the vse of Ligaments) passing through the futures or seames of the scull. For euery one of these Ligaments are extended ouer that part of the scull against which they issued, and going on meete one with another and are exactly vnited so that all of them put together make a common Membrane. This Membrane dooth not onely encompassse the scull, but also the temporall Muscles, although the Anatomists commonly take it in that place for the coate of the temporall Muscles or for a Tendon of them, making them to haue two Tendons, one outward, and another inward, whereas indeed saith *Falopius* in his obseruations it is nothing else but a part of the *Pericranium*. Yet doth it not clothe these Muscles so farre as to their insertion, but onely as farre as the Iugall bones and that for their safegarde; and the better it may doe them this good turne because in that place it is thick and hard; it parteth therefore from these Muscles neere vnto the Iugall bone as is said, where betweene the Membrane and the Muscles on either side there is a little what of *Fat* to be found.

His vse.

Platerus.

Periostium.

Falopius.

Baubine.

How the
Bones feele.

The vse of this *Pericranium* is to binde and rowle the scull on the out-side round about as it were with a rowle or swathing band whereby his bones are firmid; it knitteth also the *Dura Meninx* to the scull, and hangeth it so that it cannot fall or presse vpon the Braine. *Platerus* addeth that it tieth vnto it selfe the skin of the head and that very strongly, because there is no flesh nor fat betweene them, and that is the reason that onely the skinne of the head when it is wounded needeth not to be sewed together, because the lippes of it doe not not cannot start farre asunder being held together by this Membrane.

Next vnder this lyeth the *Periostium*, which saith *Vesalius* you may seuer from the *Pericranium* with the point of a knife, although *Falopius* thinke they are both one, and *Laurentius* conceiueth that Anatomists are deceiued by the thicknesse of the *Pericranium*, which heere was necessary because it couereth a noble bone. But *Baubine* whom we will now follow describeth them seuerally. The *Periostium* therefore is a Neruous Membrane and therefore very strong and thin. It cleaueth very strongly to the scull as also it doth to the rest of the bones; the reason is, because the bones being very hard substances would not bee altered or affected with any object, and so want the benefit of the Tactile quality, vnlesse they had benee couered with this Membrane of exquisite sense, by whose assistance now they are not destitute of feeling; whence by the Grecians it is called *περίοστος*, that is, *Circum ossalis* about the bone; for it compasseth all the bones excepting the teeth onely saith *Varolius*, but we may also except the inside of the scull and the articulations or ioynts of the bones; for if it had benee extended ouer the ioynts wee could not haue moued them without paine. Some, saith *Columbus*, being

FIG. III.

being ignorant of this membrane haue maintained that the bones themselves are not destitute of sense.

The Muscles about the head are very many, some arise from the lower part of the scull, others are disposed vnder the skin of the fore-head mouing it for the behoofe of the eyes, whereupon the skinne of the fore-head is rugous, full of transuerse and right lines; some also there are couched vnder the hairy scalpe, sometimes (for they are not perpetuall) by which the whole scalpe and the eares in some men are moued; Finally, others belong to the neather iaw (for the vpper is immouable) of all which wee shall particularly entreate in our Booke of Muscles.

The muscles
about the head

CHAP. IV.

Of the diuers Figures of the Head, the Sutures and substance of the Scull.

BEfore we come to entreate of the Bones and Sutures of the scull, which we purpose in this place but lightly to handle, it shall not be amisse to adde a little to that which hath beene already said concerning the whole figure and fashion of the head, because if the figure be changed then must the Sutures or seames needs alter both in scituation and in number, as *Hippocrates* saith in his Booke *de Ossibus*, and after him *Galen* in diuerse places, although I know that there are some great Anatomists who are not of this minde.

Table 1. sheweth the Figures of the Head. Figure 1. exhibiteth the Naturall and blamelesse conformation of the Heade on one side, the other 4. Figures are all depraued and faulty.

TABVLA I.

FIG. II.

FIG. III.

FIG. I.

FIG. III.

FIG. IV.

The Figure therefore of the head is double, Natural & Good, or else depraued. The Natural Figure [table 1, figure 1.] is that which is like a long spheare, on both sides neere the temples by little and little depressed and made narrower, but at each end shooting out; yet so that the back part is more capacious, that so it might stand vpon the Necke equally balanced. For because the fore-part though it be not so much embowed, yet by reason of the bones especially of the vpper iaw, is some-what heavy, it was needfull that the back-part should bee made as heavy by the capacity thereof.

A double fig.
of the head.
Naturall.

The depraued Figure is what soeuer varieth from the former description. I dare not call it in opposition to the former vnnatural, because some very good Anatomistes haue interposed their iudgements and determined that all figures of the head are Natural, albeit they vary somewhat from the exact forme: yet *Archangelus* calleth these depraued figures *Præter Naturam*.

Depraued 5.

This depraued Figure *Galen* in his

his ninth Booke *de usu partium* and the 17. Chapter called by a Generall name $\rho\epsilon\zeta\delta\gamma$, for in that place he reckoneth the round and globy head as a kind of that $\rho\epsilon\zeta\delta\gamma$. There be three sorts of them. The first [*tab. 1, fig. 2.*] wherein the eminence or out bearing before, shooting from the vpper part of the fore-head is wanting, although the backward eminence in the nowle be faire to be seene.

The second is quite contrary vnto this, in which [*tab. 1, fig. 3.*] the backward out-shoot in the nowle is wanting but not that in the fore-head.

The third [*tab. 1, fig. 4.*] in which both the eminences or out-shoots are wanting. There may bee another added to these three which many esteeme but onely imaginary, and that is when the skull swelleth more in compasse toward each eare then it doth either forward or backward. For *Galen* in the place next above named saith and proueth (or at least seemeth so to doe) that this is a meere speculatine thing, but cannot be indeed in Nature, for then saith he the fabricke of the braine must needs bee ouerthrowne, yea it would proue a Monster and cannot liue. *Vesalius* is of opinion that *Hippocrates* maketh mention of this forme, and beside telleth a Story of an Innocent (as wee tearme them) or foole in *Venice*, whose braine was of that shape; *Falopius* gain-saies him, and aoucheth that *Hippocrates* made mention onely of three sorts, and that he mistooke the figure of the childs head at *Venice*, of the same minde also is *Eustachius*.

A fifth Figure.

There may bee a fifth figure added out of *Hippocrates*, and that is an acuminated or sharp figure, wherein the last figure is but a little altered. This figure, saith hee in his Booke *de aëre aquis & locis*, and the 35. Text, was first made by Art: for the Midwiues vsed to presse the heads

Table 3. Figure 8. Sheweth the fore-side of the Skull, as also the bones, the holes or perforations and the Sutures both of the Skull and of the upper Jaw.

TABVLA III.

- FIG. IIX.**
- AA**, A hole in the fore-head bone.
BB, The hole of the fourth bone of the vpper Jaw, which is in the Cheeke.
C, A hole of the second bone of the vpper Jaw, in the inward angle of the eye.
DD, The fourth hole of the wedge-bone in the outward side of the eye.
EE, The first hole of the same bone.
G, The second hole.
H, The third hole of the same bone in the seate of the eye.
II, The fore-head bone.
K, The left bone of the *Sinciput*.
L, The left bone of the temples.
M, The mammillary proceffe of the temples.
NN, The Wedge-bone.
III, The first bone of the vpper Jaw.
Δ, The second bone of the vpper Jaw.
Θ, The third.
Λ, The fourth in the left eye.
Ξ, The fifth bone of the vpper Jaw in the nose.
OO, The bridge or partition of the Nostrils.
P, The Suture in the yoke-bone.
Q, A part of the second common suture from the first *N*, to *S*.
RSTVXYZ, The third common Suture drawne oblique through the Orbe of the eye.
d, The first externall Suture of the vpper Jaw in the Cheeke, and from thence through the eye to *Q*.
b, The third externall Suture of the vpper Jaw from *b*, to *c*.
c, The second externall Suture of the vpper Jaw in the eye.
e, The fourth externall Suture reaching to *Ξ*.
f, The 6. externall suture of the vpper Jaw in the middle of the nose.
g, The second internall Suture in the Nose.
h, The seventh externall Suture of the vpper Jaw.
i, A bastard Suture of the vpper Jaw at the eye.

Fig. 9. sheweth the Basis of the Skull, and many holes and Sutures therein.

CC, The lower additaments of the lambdall suture on either side.
D, The fourth hole of the wedge-bone in the outside of the orbe of the eye.
E, A part of the fourth proper Suture.
H, The great hole of the *Occipitium* made for the Spinall marrow. **K**, A part of the bone called *Sinciput*. **LL**, A part of the fore-head bone. **MM**, The lower part of the nowle bone. **N**, A rift or cleft of the Wedge-bone which is common to the bones of the temple, drawne on the left side from *n*, to *a*. **OO**, The Wedge-bone. **P**, His foure processe marked 2, 3, 4, 5. **AR**, The sixth hole of the Wedge-bone at the bottome of the throte. **A**, The seventh hole of the same at *R*. **I**, The first bone of the vpper Jaw. **S**, **Δ**, The fourth. **Π**, The sixth, where the cutter betwixt *c*, and *π*, hath not well expressed the Suture. **TT**, The bones of the temples on either side. **V**, The fourth hole of the bones of the temple made for the hearing. **Ξ**, The bridge or partition of the nose. **X**, The first hole of the temple bone in his Basis. **ΥΥ**, The yoke bone. **aa**, The anterior part of the fourth proper Suture. **b**, The lower part of the fifth proper oblique Suture. **c**, The lower part of the bridge of the nose which is like a coultter where 3. is placed. **d**, The vpper part of the second common Suture. **f**, The first externall Suture of the vpper Jaw in the Cheeke. **g**, The first common Suture in the side of the brow. **h**, The cavity of the temples whereto the lower Jaw is articulated. **i**, The *Appendix* of the temple bone called *Styloides*. **k**, The mammillary proceffe of the same temples. **ll**, The knob of the nowle bone. **mm**, The 6. proper oblique Suture of the Skull. **nn**, The seventh transverse Suture. **op**, A line beginning from the last named Suture which climeth by the temples, and is more like a diuision then a line. **qq**, The lower part of the 2. common suture of the Skull in the hollownes of the nose. **r**, The line of the hole of hearing. **sa**, The stony bones. **tv**, The 5. externall transverse suture of the vpper Jaw. **xy**, The 7. externall right suture. **αβ**, A bastard suture of the vpper Jaw in the Palate. **γ**, The hole of the eare. **δ**, The 5. hole of the temples nere vnto his proceffe where *γ*, should be blotted out. **B**, A hole of the nowle bone which is not alwayes found. **E**, The 2. hole of the nowle bone made for the 6. coniugation of the sinews and for the iugular veine and artery. **H**, The 1. hole of the *Occipitium* or nowle bone for the passage of the marrow. **3**, The 3. hole for the outgate of the 7. coniugation. **αα**, Two holes of the nose. **μν**, Two holes in the Pallate which is accounted the 4. of the Wedge-bone. **ξ**, Five holes in the Basis of the Wedge-bone. **π**, The hole of the 4. bone of the vpper Jaw in the Palate. Note that **M**, **V**, at the right side pointeth out the cavity which the yoke bone maketh for the passage of the temporall Muscles.

heads of Infants lightlie on euery side to make them rise sowewhat toward the crowne and after so rowled it with bands till that forme was confirmed; the reason was saith *Hippocrates*, because the people had an opinion that it was a signe of a generous and noble disposition to bee so featured; afterward Nature imitated Art and children were so borne; *Quintilian* in his second Booke and 17. Chapter, saith that *Pericles* had an acuminated head and somewhat long, and his words came thronging and thundring out, not peaceably as other men; so we see, saith *Bauhine*, that most of the French and low-Country men haue long heads, because they vse to lie with their heads vpon their Temples or on one side: whereas the Germanes haue most what round heads, because from their very infancy they lye vpon their backs.

Finally, *Vesalius* maketh mention of a Begger of *Bononia*, whose head was foure square, sauing that it was a little broader then long. And my selfe haue scene in *Lincolneshire*, a wondrous smal head made very like the ridge of a house neere vnto sharpnes al the length through, that boy was a foole and a wondrous great eater; and so much of the figures and fashions of the head.

A Sixt.
A Seuenth
scene in *Lincolneshire*.

The skull.

The skull or *cranium* is all that bone which compasseth the braine and after-braine like a helmet, which is not made of one bone, least this braine-panne by one wound should be broken throughout, as we see a pot wil be, the rift running quite through from the top to the bottom. It is made therefore of many bones ioyned together with sutures or seames like the teeth of 2. sawes set one against the other [table 1, and table 5, figure 13.]

Proper sutures
True.

These sutures are of two sorts, Proper and Common. The Proper sutures are either true or false, the true sutures are three, two of them transuerse, the third runneth along the head.

The first is that which is in the fore-part called *Coronalis* [table 2, A B, table 4, figure 11 n n] and distinguisheth the fore-head bone from the bone of the *Sinciput* [table 2, L, from I, to K.]

The second suture is in the nowle [table 2, C D, table 4, P P,] and is called *Lambdoides*, separating the bone of the nowle or *Occiput* [table 2, M, from I to K,] from the bone of the *Sinciput*: this suture is sometimes double, contayning in the middle a bone with three corners called *Triangulare os*.

The third suture is in the middest betwixt these two [tab. 2, fig. 1, E, tab. 9, fig. 2, O O] and is called *Sagittalis*, it is a straight seame and diuideth the bones of the *Sinciput* [tab. 2, fig. 6, I K] descending sometimes euen to the nose, especially in women.

False sutures.

The false sutures are not so conspicuous as the former; some reckon foure.

The first are two, on either side one aboue the eares and [tab. 2, F G H] aboue the bones called *Petrosa* or the rocky bones. They are not properly called sutures, but are rather scaly agglutinations. The second two belong to the bone called *Sphenoides* or the Wedge-bone, on the forepart and the hindpart.

Common sutures
true.

The common sutures are those that belong as well to the skull as to the vpper iaw, and they are five. The first is in the outside of the brow. [tab. 2, Fig. 6, and 7, g g, tab. 3, Fig. 8, R, Fig. 9, g.]

The second is double, the vppermost is in the outside of the eye and the hollow part of the Temples [tab. 3, Fig. 8, from s to 2, at Fig. 9, at d, tab. 2, Fig. 7, at d] The lowermost is at the sides of the pallat. [tab. 3, Fig. 9, from d to e,] The third is in the inner and laterall part of the eye. [tab. 3, Fig. 8, R S T V X Y Z] The fourth runneth through the middest of the Iugall bone [tab. 2, Fig. 6, X, tab. 3, Fig. 9, Y, Fig. 8, P.] The fift is in the bredth of the nose and is common [tab. 3, Fig. 9, vnder 2, to the *Sphenoides*, or wedge-bone and the bridge of the nose.

The vses of the
sutures.

The vse of the sutures is to giue way to the thicke and soory excrements; againe to tye the *Dura Meninx* to the Skull, and to giue way for the filaments of the same which make the *Pericranium* and *Periostium* as is sayd; and finally to giue ingate and outgate to the vessels.

The substance
of the skull.

Beside the sutures, the skull it selfe is crasse, rare and full of holes. Crasse or thicke for the security of that therein contained. Rare that it might not be too great a burthen; and full of holes [tab. 4, Fig. 11, 12, L, tab. 5, Fig. 14, e] to giue way to the transpiration of soory excrements.

His tables.

It is also made of a double table as we call it, or of 2. leaues [tab. 5, Fig. 14, 40] which may best be distinguished about the place of the browes; the outward of these may be eaten away by the French disease, the inner remaining sound. Betwixt these tables are conueied veines and arteries for the life and nourishment of the skull, among which vessels there is a kinde of medullous or marrowy substance [table 5, Figure 14, betwixt a, and O C] which some call *Meditullium*. These Tables are oftentimes perforated in many places

Meditullium.

places but without order, thorough which perforations small vessels passe into the inward cavity even to the *Dura Meninx*. On the out-side the skull is smooth, but if you turne the bottom vpward it is full of inequalities and protuberations. Of all which we shall entreate more at large in our Booke of Bones.

The perforation.

CHAP. V.
Of the Bones proper to the Skull.

THe Bones of the Head are of two sorts, some are proper to the Skull alone, some belong to the vpper jaw also. The bones proper to the Skull alone are six in number. (for wee goe not now precisely to worke to account the small bones of the eares) those of the jaw two.

The proper bones of the Head.

Table 4. Figure 10. sheweth the inner and lower part of the Skull, together with many holes especially those of the Wedge-bone. Figure eleventh sheweth the upper part of the inside of the Skull cut from the lower.

TABVLA IIII.

- A, The Wedge-bone.
B, His first hole.
C, The corner of that hole.
D, The anterior transverse canities of this bone in which the Optick nerues are hidden.
E, The latter of these fouresquare wherein the pituitary Glandule lyeth.
F, The forward passage, through which the Flegme gathered together is deriued.
G, The second hole of the Wedge-bone in the vpper part of the orbe of the eye.
H, The third in the bottome of the eye.
I, The small holes of the spongy bone.
K, A cleft of this bone through which the *Dura Meninx* istied.
L, 10, 11, The cavity of the forehead bone betwixt the two Tables.
M, The Wedge-bone in this place hath oftentimes a perforation.
N, A cleft or slit common to the Wedge-bone and bones of the Temples.
O, The last hole of the Wedge-bone.
P, The sixth hole.
R, The 7. hole in the chops at the bottome of the throat.
SS, 10, 11, and T, Certain inscriptions or furrowes in the Skull, impressed by the veines of the *Dura Meninx*.
V, The eighth hole of the Wedge-bone at the nostrils.
X, The fifth hole of the same bone.
Z, 11. The Fontanell.
ZZ, A cavity made for the forward extuberations of the braine.
a, The sixth hole of the Temple-bones, which is the fourth for the hearing.
b, The second hole of the nowle-bone.
c, The third.
d, The first.
e, The second.
fg, The two Posterior canities of the Skull.
h, 10, 11, The extremitie or end of the third and middle cavity.
ii, 11, A Bosome of this passage running thorough the length of the Skull.
i, 10, A Bosome common with the nowle-bone.
m, 11, Certain small holes in the inside of the bone of the *synciput*.
nn, 11, The Coronall Suture.
oo, 11, The Sagittall Suture.
pp, 11, The Lambdall Suture. q, 10, 11 The 4. Suture called *Squami-formis*. rr, The forepart of this Suture compassing some part of the Wedge-bone. s, A part of the Lambdall Suture, which some call the 6. proper suture. t, A line that ioyneeth the ends of the Lambdall suture, called by others the 7. proper transverse oblique suture. u, The eight proper transverse suture. v, The bridge or partition of the spongy bone. w, The processes of the Wedge-bone called *Clinoides*.

FIG. X.

FIG. XI.

The

The fore-head
bone.

The first bone of the scull is called *Os Frontis* the fore-head bone: [tab. 2, fig. 6, 7, L, tab. 3, fig. 8, M] it is circumscribed with the Coronall suture, [tab. 2, fig. 6, C, fig. 7, AB] and that which is common to the head and the vpper iaw. [tab. 3, fig. 8, R, tab. 2, fig. 6, and 7, 8] In this bone on either side the browes [tab. 4, fig. 10, and 11, at L] there is a notable bosome or hollownesse, wherein is contained a soft and medullous matter, or happily it was framed to containe aer for the sense of smelling. It hath two processes, the one reaching toward the lesse, the other toward the greater angle of the eie, and make the vpper part of the orb thereof. The second and third are called *Ossa sincipitis*, [tab. 2, fig. 6, IK] they are full of dens or small holes on the inside with many inscriptions like the path of a snail or Emmet [tab. 4, fig. 10, and 11, SS] where the vessels run. They are fouresquare, of substance in respect of the rest very thin and weak. They are limited backward by the Lambdall suture [tab. 2, fig. 6, DC] forward by the Coronall [tab. 2, fig. 6, AB] and below by the scaly sutures of the Temple-bones. [tab. 2, fig. 6, GFH]

The sidebones
Ossa sincipitis.

The Noddle
bone.

The fourth is called *Os occipitis* the Noddle or Nowle-bone. [tab. 2, fig. 6, and 7, M, tab. 3, fig. 9, MM] It is ioyned aboue to the bones of the *sinciput* [tab. 2, fig. 6, IK] by the Lambdall suture; [tab. 2, fig. 6, CD] at the sides to the Temple-bones, [tab. 3, fig. 9, in C] in the middest to the wedge bone. [tab. 3, fig. 9, OO] The figure of it is almost round, the substance is very thicke and hard, yet but thin and weake at the side of the great hole made in it, [tab. 3, fig. 9, H, tab. 4, fig. 10, d] through which the marrow entreth into the racke-bones of the Necke. It hath nine bosomes or hollownesses. On the inside seven, on the out-side two. Fiue holes or outlets, and lastly two processes or heads [tab. 3, fig. 9, II] broad, couered with a Cartilage or gristle which are inserted into the cauires of the first rack-bone of the neck vpon which the head is moued. Backward it hath a small processe like a tooth which is receiued by the first racke-bone.

The temple-
bones.

The fift and the sixt are called *Ossa temporum* the temple bones, or *Lapidosae* the stony bones. [tab. 2, fig. 6, and 7, N, tab. 3, fig. 9, TT] They are ioyned aboue by the scaly suture [tab. 2, fig. 6, 7, FGH] to the bones of *sinciput*, below to the additament of the nowle-bone by the sixt suture, [tab. 3, fig. 9, mn] to the first bone of the vpper iaw by the fourth common suture. [tab. 2, fig. 6, Y] Each of these hath foure processes. The first is called *Mamillaris*. [tab. 2, fig. 6, and 7, K, tab. 5, fig. 8, M, fig. 9, K] The second is called *Styloides*. The third *Labyrinthus*, conteyning the small bones of the eare. The fourth is a part of the Iugall bone.

CHAP. VI.

Of the two Bones common to the Scull and the vpper Iaw.

The Wedge-
bone.

He two Bones which belong as well to the vpper iaw as to the scull, are called *Sphenoides* or the Wedge-bone, and *Spongoides* the spongy bone, called also *Cribiforme* or *Ethmoides*. The first is set like a Wedge (whence it hath his name) betwixt the bones before described and the bones of the vpper iaw, so that it toucheth them almost all. In infants it is made of foure bones, but after we are growne it also groweth into one entire bone. And because it hath many processes and inequalities on both sides, a man can compare it to no one thing, wherefore the Ancients called it *πολύμορφον*, as if we should say, *seare-shaped*. i. seuerally shap'd.

The substance of it is fast and strong, but the inside somewhat spongy. It hath many processes, two on the inside called *nasales*, two called *pterygoideis* like Bats winges, & foure small ones which make the *saddle* or seate.

It hath also many hollownesses or bosomes, some outward in the wingy processes, others inward, in which [tab. 4, fig. 10, at C] the Optick nerues are ioyned, then the saddle it selfe wherein is the glandule placed [tab. 4, fig. 10, E] which receiue the Phlegme, from whence afterward it floweth into the Palate and the Nofethrils.

It hath also many canities and ten holes, fiue in the orbe of the eye, and other fiue in the basis of the scul. The exact description of all which you must looke for in the book of Bones.

The Spongy
bone.

The second bone common to the Scull and the vpper Iaw is called *Spongoides* or *Ethmoides* *Cribre-forme*, because it is ful of holes as a siue or seare, but it may better be called the spongy bone, because the holes are not for the most part direct, but crooked & oblique like the pores of a sponge.

It is placed in the fore-part of the Skull without the meninges, and occupieth almost all the

Table 5. Figure 12. sheweth the inside of the wedge and spongy bones. Fig. 13. Two portions of the bones of the Sinciput a little disioyned the one from the other, that the frame of the Suture might bee better perceived. Fig. 14. sheweth a part of the bone sinciput divided with a saw from the rest of the same bone, the better to exhibite the substance of the Skull.

XIV.

- A A. The spongy or the eight bone.
- B. A bridge or partition diuiding the Organs of smelling.
- C D. Two cauities of the wedgebone.
- E. A partition distinguishing them asunder.
- F. A hole of one of the Cauities ending in the Nostrils.
- G. A right Cauity scituated vnder the two former.
- HH. Processees like to Bats wings.
- 14. The vpper or exterior Table 4, the interiour.
- 14. A cauernouse or spongy substance in the middest betwixt them called *Diplois*.

the cavity of the nose; it is ioyned to the middest of the bottome of the forehead bone, [Tab. 4. fig. 10, K] and is distinguished from the wedge-bone by the bastard seame called a Harmony, which is accounted for the ninth Suture. [Tab. 4. Fig. 10, above u] There are foure parts of this bone. The first is an vpper processe in the midst, long and triangular like a Cock-combe. The second is on both sides that processe [Tab. 4. Fig. 10, K I. Tab. 5. Fig. 12, A A] which is couered with a thin Membrane likewise perforated. The third is a lower processe opposite to the vpper which diuideth the vpper part of the nose into two parts. The fourth part is the substance it selfe of the *sponge* from whence it hath his name. The vse of it is to admit aer for the generation of Animall spirits, to admit vapours to the sense of smelling; but the pores of it are not direct but oblique & crooked, lest the cold aer should too directly ascend vnto the braine to refrigerate or coole it ouermuch.

The vse of it.

CHAP. VII.

Of the Meninges or Membranes of the Braine.

the lower belly and parts therein are compassed with the *Peritonæum*, & the middle with the *Pleura*, so there are two membranes stretched ouer the cavity of the Skull, which *Galen* and those who haue written since his time haue called *μνιρυς*. And indeed *Galen* had the name out of *Hippocrates* his booke de *Carnibus*, who there taketh it in a larger signification, which giueth

Galen.
Hippocrates.

that name to all parts that are hollow, as the veines, the stomacke the guts and such like. *Erasistratus* called these membranes *εμμενιδες*, *Pollux* *εμμενιδες*. The *Arabians* called them *Maters* the Mothers, and so now they are commonly tearmed. *Macrobius* called them *Omenta* or *kelles*. The one of these which is the outward is thicke and called *dura mater* the hard Mother, the other inward and thinne called *pia mater*, the deere or neere Mother, because it immediately incompasseth and imbraceth the substance of the braine.

Their names.

The *dura mater*.

His figure and magnitude.

Connexion.

Whether the braine mooue or no.
Platerus,
Columbus, *Archangelus*,
Laurentius.

It is double but not two.

The thicke *meninx* *Hippocrates* (in his booke *de locis in homine*) calleth *σκληρὴ* or *παχὴ* or *σκληρὰ δὲ μὲνινξ* that is, the thicke hard or skinny *meninx*, commonly the *dura mater*, because of all the membranes of the body it is the thickest, hardest and strongest, and particularly in relation to the thinner *meninx*.

In figure and magnitude this membrane answereth the bones of the Scull, because it incompasseth all his bosomes and cavities. It is greater then the *pia mater* or thinner *meninx* least if it lay too close vnto it the vessels that runne therein should bee compassed, which if they bee distended and swell too full of blood, doe cause the head-ach, yea oftentimes the Apoplexie; whence it is that many which dye of the Apoplexie, auoid blood out of their nose and their mouth.

It is tyed very strongly to the Basis of the Scull and to his sharper processe, and to the orbes or circles of his holes, [Tab. 11, fig. 7, 22] whereupon some haue thought that from this Basis it tooke his originall, because seede is the matter out of which this, as all other membranes are made. Notwithstanding it cleaueth not so close to that bosome of the wedge-bone [Tab. 4, fig. 10, E] where the Glandule of phlegme is situated, [Tab. 7, Fig. 15, A] nor yet at the sides thereof where those bosomes are which giue way to the branches of the sleepey arteries called *Carotides*. It incompasseth all the inside of the Scull, from which as also from the braine it hangeth in the like distance as doth the *Pericardium* or purse from the heart, least the eleuation and depression, or *Systole* and *Diastole* of the braine should bee hindred. I know full well (that wee may say something of it by the way) that *Platerus* thought that the braine it selfe did not moue, but that it was onely the pulsation of the third ventricle much like the beating of an artery, which wee feele in the Sculs of tender Infants before their bones are ioyned close together. But *Columbus* and *Archangelus* doe demonstrate a manifest *Systole* and *Diastole* of the braine from their experience in those whose Sculs are wounded and the bones taken out with a Trepan. And *Laurentius* thinketh him not worthy the name of an Anatomist that wil call it into question.

It is tied very strongly to the Scull by thinne and membranous fibres (which *Galen* in the 8. booke of the vse of parts and the 9. chapter, calleth *Ligaments*) arising there-from, which passe through the Suture of the Scull, especially about the *Lambdall Suture*, euery one of which *Ligaments* or fibrous ties chuse you whether, are extended over the parts of the Scull where against they issue, and running along are exactly vnited together and make that common Membrane which wee saide before was called *Pericranium*, vnder which there is yet another farre finer and thinner called *Periostium*; from which two membranes all the other membranes of the body haue their originall, that in this respect this *Dura meninx* may well be called *Mater*, as being the Mother of all other membranes. It is also knit to the *Pia mater* and to the braine by the mediation of vessels [Tab. 6, Fig. 2, DD GG. Tab. 11, fig. 8, xx.]

This membrane is double as are the rest of the membranes of the body; and *Columbus* makes two membranes of it, one inward another outward, and boasts himselfe of the finding of them: whom *Laurentius* closely taxeth confessing that it is indeed double, but they are not therefore to bee called two membranes; so saith he, we do not say that there are two rims of the belly, and yet wee know that the *Peritoneum* is double. Well, it hath a double superficies or surface; the outward like a broad Tendon is stretched ouer the other and groweth vnto it; hard it is and rough, partly by reason of the fibres which if you take away a piece of the Scull you may perceiue a little to swell vp like a small line, [Tab. 6, fig. 1, GGG. HH, II] partly because in the crowne of the head where the sagittal Suture meeteth with the Coronall, there are certaine small knubs or knots, which in the Scull haue their proper bosome wherein they couch and to which they grow very fast. [Tab. 6, fig. 1, K.]

The inner superficies or surface is bright, smooth, slippery and much whiter without any such knubby or kernelly substance or fat (what you will call it) at all; moistened also with a watery humor, [Tab. 6, Fig. 2, HH] whereas the vtter is dryer. On the inside also it is of exquisite sense, but on the outside not so that it might better endure the contraction of the bone

Table 6. Figure 1. is covered with the gathering with the *pia mater*.

FIG. 1.

bone without offense. It hath many bones, and the 6. chapter negations or paires and that round as also others at the 12. Fig. 11, C and D descendeth out of the gy bone, it is perforated in the top of the and a left, even as a plication lyeth all a the bosome through

Table 6. Figure 1. sheweth a head, the scull being taken away, that so the braine may appeare as it is covered with the dura meninx. Figure 2. sheweth the Braine cleared from the Dura meninx, together with the third Sinus thereof, divided through the middest, which is shewed covered with the Pia mater.

TABVLA. VI.

FIG. I.

II.

AA, BB. The Dura meninx or thick membrane.

CCC. The third Sinus of this membrane.

DD, The course of the veines as they run through the membrane, or the second veine of the braine.

EE. The first veine of the braine.

FFF. Certaine small veines which perforate the scull and reach to the pericranium or Skull-skin.

GGG. Fibres of the Dura meninx passing through the Coronall Suture, which fibres make the Pericranium.

HH. Fibres passing through the sagittal Suture.

II. Others passing through the Lambdall Suture.

K. A knob which vseth to grow to the Sinus of the Scull.

L. A cavitie in the forehead bone.

M. The Scull.

N. The Pericranium or Scull-skinne.

Fig. 2.

AAA. A part of the Crasse meninx diuiding the braine.

BB. the third Sinus of the same Crasse membrane opened.

CC. the beginning of the vessels out of the third Sinus into the Pia mater.

DDD. the propagation or brâches of these vessels. EEE. the Pia mater or thin meninx immediately compassing the braine. FFF. Certaine vessels running through the conuolutions or branches of the braine.

GGG. Certaine brâches of veins running through the sides of the dura meninx.

HHH. The thicke membrane reflected downward.

bone without offence.

It hath many holes or passages in it, first of all (saith Galen, in his 9. booke of the use of parts, and the 6. chapter) to giue way to many veines; againe, for the outgate of the Coniugations or paires of the sinewes. Moreover in the middest it hath one notable perforation and that round, to let out the braine Tunnell, called *Infundibulum*, [Tab. 12, fig 11, F] as also others at the sides of the former to admit the sleepey arteries called *Carotides*, [Tab. 12, Fig. 11, C and D] and one larger then all the rest through which the marrow of the back descendeth out of the braine. [Tab. 12, Fig. 9, H] Finally, where it is stretched over the spongy bone, it is perforated manifold like a Sieue. [Tab. 14, Fig. 18, at F, and figure 9, at FF.]

In the top of the head it is redoubled and separateth the braine into two parts, a right and a left, euen as low as the center thereof. [Tab. 10, Fig. 13, from D to B] Which Reduplication lyeth all along the third bosome or Sinus of this hard membrane & runneth with the bosome through the length of the head forward vnto the top of the nose, and groweth fast

His holes or Passages

His Reduplication.

fast vnto the distinction of the mamillary processes, [tab. 9, Fig. 3, N] euen as it groweth backward in the middest to the hinder proceffe.

The Sythe

This Reduplication of the *dura meninx* is called the vpper proceffe and is likened by all the best Anatomists to a Mowers Sythe, and *Laurentius* is not affraid to call it *Falx* or the Sythe, and saith that this reduplication makes the body of the same: but *Vesalius* saith that the proceffe which is like a Sythe is not duplicated but simple as the membrane it selfe is simple, and seemeth onely to bee double because of the bosome which parteth the braine, of the same kinde also is *Platerus*. But let vs see how it resembleth a Sythe: *Bauhine* fashioneth it thus. Backward, (where it is continuall with a part of the same membrane which couereth the *Cerebellum* or after-braine) it is broad and answereth the broad end of the Sythe, [tab. 9, Fig. 3, as D] about the middest of his length it groweth to bee very thicke like the backe of the Sythe, and the fore end is like the point, for it groweth narrow by degrees and therefore that part of it which is next to the braine turneth inward obliquely iust like the hooking point of a Sythe. [tab. 9, Fig. 3, from FG to H.]

The other proceffe of the *Dura Meninx*.

The other proceffe of the *Dura mater* is backward and shorter, and for the most part distinguisheth the *Cerebellum*, or after-braine from the braine it selfe, [tab. 11, Fig. 7, 0000] Beside it couereth the *Cerebellum*, and it is foure-fold as thicke and hard as it is in any other place saith *Columbus* and with him *Archangelus* and *Laurentius*, *Vesalius* saith three-folde. Dogges in this place haue a bone which vnderproppeth the braine that it should not lye heavy or beare vpon the *Cerebellum*. [tab. 11, Fig. 7, betwixt 00 and XX.]

A bone in Dogges.

Two kinds of Cauties.

In this membrane there are found two kinds of Canales or pipes; one through which the vessels are carried, as the Arteries which are disseminated through the membrane. The other into which the veines do determine, which kinde of Canale or hollow passage is to it instead of veines; and these they call the backward bosomes, or hollowneses, or Canales, (for other words to expresse a *Sinus* I cannot deuise) of which we will immediately intreate.

Fallopins his ten *Sinus*.

Fallopins in his obseruations reckoneth ten of these *Sinus*, on either side foure; the ninth is that which other Anatomists take for the third, and the tenth that they take for the fourth; but in his institutions hee reckoneth but sixe: foure of which we know well, the other two saith *Bauhine*, I thinke no man knowes but himselfe.

Foure *Sinus* of the *Dura mater*.

We with *Bauhine* (whom for the most part we follow) do reckon foure, which *Galen* in the ninth booke de *Anatomicis Administrationibus* called *σπλάγχις*, in the 9. booke de *usu part.* and the 6. chap. sometimes *meningis σπλάγχις* leading blood: sometimes *τὴν παχέαν μνίγγα* *νοτίαν* the ventricles of the thicke membrane; as in his 9. booke de *Anatomicis Administrationibus* and the fift chapter, because they arise from the duplication of the membrane, and are as it were Rillets carrying blood and spirits. And haply hence tooke *Pelops* the occasion of his error, who auouched that all the vessels had their originall from the head.

Pelops his error whence. The two first *Sinus*.

The two first of these *Sinus* or Canels, or Rillets, (call them as you please) haue their beginning behind in the Basis of the *Occipitium* or nowle betwixt the braine and the after-braine at the sides of the hole through which the marrow of the backe descendeth: they are one on each side, [Tab. 7, fig. 13, M N] called the right and the left. They lye neere the sides of the *Lambdall Suture*, and into them doe the veines and the arteries exonerate and vnburden themselves. They are fastened to the Scull, and when they come neere the middle of the *Lambdall Suture* and the top of the *Cerebellum*, they ioine in one and make a common cavity, which place [Tab. 7, fig. 13, O] *Herophylus* (saith *Galen* in his 9. booke of the vse of parts and the 6. chapter, and in the 9. of his *Anatomicall Administrations* and the first) called *λυστή* that is, *Torcular* the presse, because from thence as from a high place the Rils runne downe on either side; some of them out of the middest of it are deriued into the whole after-braine, others run from the forepart, from whence, as wine from a grape-presse, the blood poured out of the veines and arteries is squeezed into the whole braine. From these on eyther hand at the sides runne small branches like veines, some of them as small as a very haire, some of them larger, [Tab. 7, fig. 13, SS] which runne out into the bordering membranes, both the thicke one [Tab. 11, fig. 7, 000] and the thinn one [Tab. 12, Fig. 9, B D] where they couer the whole *Cerebellum*.

Galen

The presse of the braine.

Out of the concurrence of these [Tab. 7, Fig. 13, O] doe arise two other *Sinus* or Rils differing in length and in the fashion of their cauities. The one of them is the higher and is called the third *Sinus* [table 15, figure 13, PP] the other the lower called the fourth [table 7, fig. 13, R]

The third *Sinus* which is like a Rill of blood (called sometimes by *Galen* a veine and not vnpro-

vnproperly (for what should you call a vessell in which blood is contained but a veine, though it haue not the coate of a veine?) though some thinke it to bee *Herophilus* his *presse* of which wee spake euen now) passeth directly forward through the length of the head [table 6. fig. 1, and 2, C C C] betwixt the right and left parts of the Braine vnder the vpper part of the Lambdall Suture and vnder the Sagittall Suture, and vnder the middle of the forehead bone and in the top of the nose is ioyned to the bony partition [tab 7, fig. 13, Q] of the organs of smelling, and would bee like a triangle, sauing that in the vpper part it is some what neere to a *semicircular* forme: for the cavity of this *Sinus*, as also of the two former, haue two crooked ribs as it were inward, and the third curued outward.

From this *Sinus* or canale on either side the braine all along the head there arise very thicke certaine vessels as it were branches out of a great trunk of a veine which *Galen* calleth *οχορτις* of which some are but small which they call *venas reptitias*, the creeping veines. Of these some arise from the higher part of the *Sinus*, some from the lower, some from the sides thereof. Those which arise out of the higher part [table 7, figure 13, XXX] which is next the skull, do runne vpward to the duplication of the skull, that is to the porie substance betweene the tables thereof, and to the *Pericranium*, and mingle themselves with those small vesselles which descend from the skinne of the crowne and passe through the skull at small pores thrilled therein for the same purpose. Those which arise from the lower part of the canale, that is, which is next the braine [table 7, figure 13, VVV, table 9, figure 3, EE, HH] are but small and runne downward onely into that part of the *dura meninx* which euen now wee called the *fithe*. Those which arise out of the sides of the *Sinus*, that is out of the bredth of it [Table 7, figure 13, TTT, tab. 8 figure 2, DDEF] are infinitely diversified into the *pia mater* and together therewith into the conuolutions of the braine; & where the *pia mater* endeth they proceed on into the very substance it selfe of the braine. These vessels sometimes opening, so great a quantity of blood hath yssued by the Nose thrills, that it is credibly reported to haue amounted to 24. pound: in which kinde of fluxe wee must not apply medicines to the forehead, but either to the crowne or to the coronall suture.

Columbus was of opinion that these vessels do not arise out of the *Sinus* it selfe, but out of the veines running threin, for he thought that the internall iugular veines passed through it. *Archangelus* also seemeth to incline this way, who sayth that though the two former *Sinus* or rils, the inner iugular veines and arteries doe passe and insinuate themselves into the third *Sinus* and so run out to the nose, yea backward also to the fourth *Sinus* and quite through it.

The fourth *Sinus* saith *Vesalius* the professors of dissection haue not remembered. It is no where neare to the skull as the others are, but seated in the lower part of the braine: very short it is and runneth directly betwixt the braine and the after-braine to that part of the braine called *Nates* or the bottocks, and the glandule called *pinealis* (for such representations there are in the substance of the braine [Tab. 7, fig. 13, R, table 11, figure 7, T] and the cavity of it is like a triangle made of three equall ribs curued inward. The beginning of this cavity, or rather truth to say the meeting of all foure [Tab. 7, fig. 13, Q] some call the *Torcular* or the presse; and from hence do spring the veines, saith *Columbus* and with him *Bauhine*, which are dispersed through the substance of the braine to nourish it.

From this *Sinus* also in his progresse doe issue small branches, some of which runne vpward to that part of the *dura mater* which is aboue the *Cerebellum* and as farre as to the *fithe*, [Table 7, figure 13, YY] others downward [Tab. 7, fig. 13, a a] which are dispersed into the *dura mater*, where it lyeth about the after-braine, as also into the *pia mater*, both where it compasseth the after-braine and the braine it selfe.

Afterward this *Sinus* is diuided into diuers rillets; two issue out of the vpper part of it and one out of the lower; of the two which issue out of the vpper part, one is greater, another lesse.

The greater [table 7, figure 13, b] creepeth along the lower part of the *dura meninx* where it deuideth the braine in his length; from which certaine furcles runne [Tab. 7, Fig. 13, c c c] vpward to the proesse of the same *dura mater*.

The lesser which is double, a right and a left [Table 7, Figure 13, de. table 3, Figure 3, II F G G] supported with a thinn membrane after the manner of veines are ledde through the length of the braine on either side aboue the callous body called *Corpus callosum*, and afford some small twigs to the *pia mater* which are distributed on either side into the braine.

The lower rillet [Table 7, Figure 13, f] is but one propagated into that part of the *pia mater* which compasseth the *Cerebellum*; but it is diuided into two branches, one of them run-

TABVLA. VII.

- A. The internall Iugular veine.
 B. The sleepe or Iugular artery,
 C. The first veine.
 D. the 2^d veine which is led vnto the Sinus.
 E. the 3^d, creeping through the dura meninx.
 F. the fourth running into the Sinus.
 G H. the 5th and 6th going to the dura meninx.
 I. the first Artery.
 K. A branch of the same Artery running through the Muscles of the necke.
 L. the second artery reaching into the sinus.
 M. the third without a companion.
 N. A small branch of the third artery.
 O. the 1st and 2^d sinus of the Dura Meninx.
 P. the congresse or meeting of both those sinus. P P, the 3^d sinus of the Dura Meninx.
 Q, the end thereof.
 R, the fourth sinus of the Dura meninx.
 S S Branches of the first Sinus deriued into the Membranes nere at hand.
 T T T T. Branches of the third Sinus disperised into the Pia Meninx.
 V V, the lower small branches of the third Sinus.
 X X, the vpper distributed through the Dura meninx.
 Y Y, certaine surcles of the 4th Sinus sent vpward. aa, Others sent downward.
 b, the vpper passage of the fourth sinus running by the Syth.
 cc. Surcles running vpward from this

passage. de. The right and left vpper branches of the fourth Sinus. f, The lower branch going to the Pia mater. g, A branch of the same passing forward. h, The same bending backward to the Choroides reflected to the Cerebellum. i, A notable vessell into the which the 4th Sinus doth determine. K, The vpper. The by-partition of this vessell in the braine. lm. Two branches of this by-partition. n. A surcle reaching to the organ of hearing. o o o, The distribution of the 3^d veine and artery. p p p, Surcles proceeding from the Branches marked with o deriued into the pia mater. q, The diuision of the third artery where it entreteth into the scull. f. A branch reaching to the hollownesse of the nostrils. t, The end of this in the extremitie of the vessell. u u, 2 branches entring into the scull. x. A branch deriued vnto the eye from the coition or meeting of the branches. u u, e, A branch attaining to the pia mater. A, A branch attaining to the right ventricle. s, The complication of vessels called Plexus Choroides formed on either side of the branch marked with A. Fig. 14. A B, Arteries climbing into the scull, and making this wonderfull net. C, D, Branches into which the surcles of that net are ioyned. E, The pituitary glandule or kernel of flegme. Fig. 15. A, the Glandule receiuing the bafon. B, the bafon it selfe, or if you will, the Tunnell called Peluis or infundibulum. CC, the sleepe Arteries. D. A Branch of the artery going to the side of the Dura Meninx. E, Another branch of the same artery going to the nostrils. FF, An artery in one side diuided into 2 branches, but in the other side meeting together againe. G, A partition of the artery creeping through the dura meninx. H, Another branch which getteth out of the scull and reacheth to the eyes. Figure 16. A, The pituitary Glandule. B, C. The sleepe Arteries going into the scull. D, D. The wonderfull Net.

neth forward [Tab. 7, fig. 13. g] through the Circles of the braine and endeth in the lower seate of the ventricle, and is ioyned with an artery ascending thither [Tab. 7, fig. 13. y] to make as they say that web of vessels which they call *Plexus Choroides*, because it is somewhat like the after-birth called *χορίον*. The other branch is reflected backward to the *Cerebellum* [Tab. 7, fig. 13. i] and is diuersly sprinkled into his *pia mater*. Finally, and at length this fourth *sinus* determineth into a notable vessell couered with the *pia mater* [Tab. 11, fig. 7, v. tab. 7, fig. 13. i] which neere the testicles of the braine, so called, is diuersly diuided and knotted and so goeth vnto the Glandule called *Pinealis* and vnder the arch of the braine called *Fornix* runneth in to the inside of the third ventricle and there is parted into a right branch and a left. The right branch reacheth [Tab. 7, fig. 13. l] vnto the right ventricle and the lefte vnto the left. [Tab. 7, fig. 13. m] & Anatomists do think that they are mingled & ioynd to the branches of the first and fourth arteries to make that *plexus Choroides* of which we made mention euen now.

Where the 4
sinus endeth.

These *sinus* or cauities of the *dura meninx* haue not the coats of veines but are in substance like to the *Meninx* it selfe. For as soone as the veine (put case the internall iugular) toucheth the scull, the *dura meninx* is there presently duplicated and the inside becommeth fistulated or hollowed like a pipe, and with these pipes as if they were veines the veines themselves are ioyned. They do the office both of veines and arteries, for they beate like arteries sayth *Platerus*, they receiue into them both veines and arteries (although *Fallopian* thinke they receiue only veines) and the blood and spirits of them both. For they are full of blood which they preserue as they receiue it full of spirits, but after death this blood cloddeth into a grainy substance, haply because the blood they receiue out of the vessels is a little thicker then ordinary saith *Bauhine*. They send also out of themselves scions and surcles like to the branches of Veines which passe vnto the Braine and both the Meninges.

The matter of
these *sinus*.

They doe the
office of veins
and arteries.

For because the Braine is large and standeth in neede of a great quantity of blood, but yet cannot admit any notable branches of Veines and Arteries to runne thorough his substance, Nature made these *sinus* or rilllets to bee in stead of veines and arteries to passe thorough and irrigate or water the whole substance thereof: for into them there is continually powred great abundance of blood which is mingled, the Venall I meane with the Arteriall, and afterward conueyed by these pipes vnto the convolutions of the Braine, yea into his very substance, aswel for his nourishment & life as also for the generation of the Animal spirits which are wrought within his substance. For seeing these Animal spirits are continually supplied vnto the instruments of sense and motion, and by motion are spent & dissipated, it was necessary there should bee great quantity of both kinds of blood in this place mingled together to make supply of them.

Why the brain
needeth much
blood

The vse of the *Dura Meninx* is, to hold together the whole substance of the Braine and bee a couering thereunto and to all the parts of it, for it compasseth about the spinall marrow also, yea and all the Nerues that yssue out of the Braine. It also defendeth the brain from the impressions of the Scull or compressions if by any outward iniury it bee beaten downward. It also preserueth the Arteries which runne in the surface of the Braine, that in their *Diafole* they be not offended by the hardnesse of the Scull.

The vse of the
Dura Mater.

Moreouer, it diuideth the Braine from the after-braine or *Cerebellum*, as also the Braine it selfe into a right part and a left. Finally, it produceth Ligaments through the futures of the scull to make the *Pericranium* and to fasten it to the scull, that it might not sinke downe toward the braine, as also to hold vp the Braine it selfe least settling downe it should presse the Ventricles which would cause sudden death. And thus much concerning the *dura mater* or *Meninx*, wherein wee haue beene somewhat prolix, that nothing might escape worthy your obseruation. Now it followeth that we intreate of the *Pia Mater* or thin *Meninx*.

The *Dura mater* being taken away we meete with the second Membrane called *Pia mater*, delineated vnto you in the first Table and the second Figure, but in the ninth Table and the third Figure P P sheweth the *Dura mater* & O O the *Pia Mater* of which we now speake. This Membrane euen considered of it selfe, as also in comparison with the other Membranes of the body is exceeding thin, and therefore called *λεπτὴ μνίνηξ* by *Galen* in his ninth Booke *de Administrationibus Anatomicis* and the second Chapter. The name he had out of *Hippocrates* his Booke of the Falling sicknesse, where hee saith that this *λεπτὴ μνίνηξ* diuideth the middle of the Braine, or the Braine in the middest. *Galen* also in his eight Booke of the vse of parts and the ninth Chapter calleth it *μνίνηξ χοροειδής*, that is the Membrane like the *secundine* or after-birth, because it conteyneth or holdeth fast the veins and arteries of the Braine, least whilst they mooue they should be displaced, their basis or foundation being but weake and infirme.

The *Pia mater*
or *tenuis Me-*
ningis.

His names:

This

His figure.
Magnitude.

Substance.

The court fell
of Nature.

This membrane is for the most part conteyned within the skull immediatly covering the braine, and there is iust of his figure. In magnitude answerable to the braine and the parts thereof; but the substance or body of it is exceeding thinne and fine, and yet *Cabrolus* and *Laurentius* say it is double. It is thinne that it might more easily insinuate it selfe into the conuolutions of the braine, and yet not be offensive by the weight of it to the brayne vpon which it lieth, & beside to carry the vessell quite through the same [Tab. 6, Fig. 2. EEE. tab. 9. Fig. 3, 00] It is soft and of exquisite sence because it communicateth the Tactile vertue to the Brayne and the Nerues; and *Archangelus* sayeth it is the very instrument of *Touching*.

This Nature placed betweene the brayne and the *dura meninx*, least the brayne saith *Galen* in his 8. booke of the *Vse of parts* and the 9. Chapter, should bee offended by so hard a neighbour. For euen as saith *Plato* betweene the earth and the fire because their natures are very contrary, God interposed the water and the ayre, so *Galen* saith that nature betwixt the brain and the skull which are partes of very different substance, hath placed these 2. membranes or meninges. For if there had bene none but this thinne *pia mater* it could not haue agreed with the skull without offence, if there had bene none but the *dura meninx*, yet the braine would haue bene therewith offended. That therefore neither the braine nor his cover should indure any vncouth violence, Nature hath immediatly covered the Braine with this *pia mater*; and then the *pia mater* hath she compasseth with the thicker; for by how much the thicker is softer then the bone, by so much is the braine softer then the thinner.

If you would know what distance there is betweene these two membranes, you must make a little hole in the thicker, and then put a hollow bugle to it and blow it, and you shall perceiue the distance betweene them will containe a great deale of ayre, by which you may imagine how farre they were seuered when the man was aliue.

The progresse
of it.

This membrane doth not onely cleave closely to the braine and couer it immediatly as his naturall coate, as a mother embraceth her infant (whence *Platerus* thinketh it was called *pia mater*) least the soft and moyst substance thereof should bee scattered or suffer diuision by the continuall motion wherewith it is wrought vp and downe (for wee perceiue that the braine will easily runne abroad when it is taken away) but also it insinuateth it selfe into the bottome of the braine, and extendeth it selfe vnto the inside of the cavity of his ventricles saith *Galen* in his 8. Booke of the *Vse of parts* and the 8. Chapter, lining them round within. The vulgar Anatomistes saith *Laurentius* thinke that it passeth into the ventricles from the vpper part of the braine; but the truth is that it ascendeth from below where the *Infundibulum* or Tunnell of the braine is scituate, and where those small arteries deriued from the sleepey arteries called *Carotides* doe passe into the braine at the sides of the wedge-bone; so that euen in the bottome it meeteth; without the skull it cloatheth the narrow of the backe and the nerues. The bones also saith *Archangelus* doe seeme to bee couered with this thinne membrane, which now hauing with his vse changed his name is called *Periostium*. But how it maketh the *Infundibulum* or Tunnell called also *Peluis* the Bason, and how it inuesteth the vpper part of the phlegme-glandule, we shall declare afterward.

Archangelus.

The vse of
the *pia mater*.

The Vse of it is, to couer and establish the braine, the after brain, the marrow of the spine and the nerues, as also all the vesselles which runne through it, it knitteth together, so that they are more safely and commodiously distributed through the whole body of the Braine & through all his parts. Adde hereto that which *Archangelus* determineth in the first Booke of his Anatomy, that it is the most exquisite and proper instrument of the sence of *Touching*.

CHAP. VIII.

Of the vessels disseminated through the Brayne.

THE vessels disseminated through the Braine are Veines and arteries and those *Sinus* or Canales whereof wee intreated at large in the former Chapter.

The veines.

The Veines are branches of the inner or vter Iugulars: the Arteries of the *Carotides* or sleepey Arteries, and of that wee call *Cernicalis* or the artery of the necke.

The inner iu-
gular.

The inner Iugular at the Basis of the skull in the backpart [table 7, Figure 13, at A] is diuided into two branches, one bigger which watereth the backpart, and another smaller branching forward. The bigger [Tab. 7, Fig. 13, the lower C] attaineth into the braine at the first

first hole of the No-
braine at the leu-

first hole of the Nowle-bone. [Tab. 4. fig. 10, b] The lesser, [Tab. 6. fig. 1, DD] getting into the braine at the seventh hole of the wedge-bone. [Tab. 4. fig. 10, R.]

The viter Iugular veine sendeth three branches into the Scull: the first [Tab. 7. fig. 13, E] entreth into the *Sinus* of the *dura meninx* through the hole of the temple bones. [Table 4. Fig. 10, e] The second [Tab. 7. Fig. 13, G. Tab. 14. Fig. 19, HH] passeth in at the second hole of the wedge-bone. [Tab. 4. Fig. 10, G] the third [Tab. 7. Fig. 13, H. Tab. 14. Fig. 19, II] is distributed into the *dura meninx*, and getteth in at the hole of the spongy bone.

The viter Iugular.

Beside these five veines, *Vesalius* and *Platerus* add another, to wit, the end of the Necke veine which entreth the Scull (say they) at the third hole of the Nowle-bone which was purposely made for it. But *Banhuine* could neuer obserue it; yet wee haue added it in the Table. [Table 7. Figure 13, D.] Thus much of the veines, now of the arteries.

Another veine of Vesalius and his finding.

The sleepey artery called *Carotis* when it is come on either side to the Chops is diuided into two branches, one exterior of which heereafter, the other interior which is the larger of the twaine. This at the Basis of the Scull [Tab. 7. Fig. 13, B] is diuided into 2. vnæquall branches. The first is a little lesse then the Trunke, [Tab. 7. Fig. 13, L. Fig. 15, CC. Tab. 14. Fig. 19, P] it pierceth the Scull through a proper hole of his owne thrilled in the temple-bone, passeth vnto the saddle of the wedge-bone and then sheaddeth a branch on each hand into the side of the *dura mater*, [Tab. 7. Fig. 15, D] & afterward being diuersly carried and diuided (as wee shall heare more distinctly in the booke of veins) it helpeth to

The arteries.

The first

The second,

The third.

A fourth.

The *Sinus* of the *Dura meninx*.

make the *Rete mirabile*. [Tab. 7. Fig. 14] and the *Plexus Choroides*. From this first issueth a branch obliquely, [Tab. 7. Fig. 13, q] and getteth into the braine at the second hole of the temple-bone, and then is diuided into two branches, the one running outward [Tab. 7. Fig. 13, f] through the eighth hole of the wedge bone into the cavity of the Nose: [Tab. 7. Fig. 15, F] the other inward, which is diuided into two, [Tab. 7. Fig. 13, uu] and after distributed into the *Dura meninx*; and this is called the second artery, though it arise out of the first.

The third artery [Tab. 7. Fig. 13, I] is the other branch of the inner trunke of the *Carotis*, much lesse then the first; getteth in at the first hole of the nowle-bone, [Tab. 4. Fig. 10, b] and so passeth into the *Sinus* of the *dura meninx*.

There is also one other artery called *Cervicalis* which is a sprout of the axillary artery, it perforateth the *dura meninx* in the side where it inuesteth the spinall marrow and entreth the Scull at the same large hole whereout the marrow issueth, and ascendeth vnto the place of the Glandule called *pituitaria* where it is diuided into two branches, which helpe to accomplish the *Plexus Choroides*.

Beside these veines and arteries, the *Sinus* of the *dura meninx* is also a vessell of the braine which

which we haue at large described before. It receiueth three veines, [Tab. 7. fig. 13, CDE] and two arteries [IK] which vnburthen themselues into it: and this *Sinus* according to his diuers course is distinguished into foure as you haue heard, which are larger then the veines that ascend vnto the Scull, but not round as they are, but rather like a triangle consisting of three ribs of an equall length and curued somewhat inward. From these do issue certaine passages like vnto veines, by which both sorts of blood Naturall and Vitall, is distributed into the substance of the braine as we haue said before.

The vse of
the veines.

The vse of the veines is three-fold, first to bring plentifull nourishment to the braine. The second, to bring a Natural influent spirit from the Liuer to nourish the ingenit Natural spirit of the braine.

The third, together with the Natural spirit to bring the Vegetable soule or power into the braine.

The vse of the
Arteries.

The vse of the arteries is to bring vitall spirits and facultie to cherish the vitall spirit of the braine, to ventilate the in-bred heate of the braine, to moue the blood in the veines which otherwise would stand and so putrifie: And finally to make the blood of the veines which is thicker heere then ordinary (as we haue already obserued) somewhat thinner that it might passe and repasse more freely.

And thus much shall suffice concerning the containing parts of the head both outward and inward, common and proper, with their appertinances the vessels. Now it is time we should come vnto the parts contained, which are the braine and the after-braine, with the spinall marrow and Nerues arising therefrom: and first of the braine it selfe.

CHAP. IX.

Of the Excellency, Scituation, Figure, Substance, and Temperament of the Braine.

A diuision of
the Head.

Being to vndertake the history of the braine, me thinkes we may make a diuision of those parts that belong vnto and fall vnder our sense into foure sorts. One sort of them that are about the braine as the containing parts already spoken of outward and inward, common and proper. Another sort of them that are within the braine as the substance thereof, the figure, the magnitude and the diuers parts which haue diuers names giuen them according to their different formes, of which we will heere and heereafter in-treate. A third sort of them that ascend vnto the braine, as the veines and arteries, of which wee spake somewhat in the former chapter, and shall do more if God permit in the booke of vessels. A fourth and last sort of them which issue from the braine, as the marrow of the backe or spine, the Nerues and the Animall spirit, of which also wee shall presently heereafter discourse: But to the purpose.

Aristotle.

Aristotle (in his 2. booke *de partibus Animalium* and the 7. chapter, and in the first booke of his History of Creatures, and the 16. chapter) saith, that all Creatures which haue blood, haue also a braine and none other, vnlesse it be somewhat proportionable as the *Polypus*.

This braine among the ancient *Greekes* had no proper name, but because of the scituation it was called *ἐγκεφαλον*, because it was contained ἐν τῇ κεφαλῇ in the head. Of the generation of it *Hippocrates* hath learnedly discoursed in his booke *de Carnibus*, to which wee referre the learned Reader; as also for the order of the generation thereof to *Aristotle* in his booke *de generatione Animalium* and the sixt Section.

The braine
the principall
part of the
whole body,
and why.

It is the principall part of the whole body which may be proued by the scituation, the figure, the defences it hath, and the vse of it. The scituation is in the highest part of the body as it were in a defenced Tower, that it might be better secured from outward iniuries.

The figure is round, which is the most noble figure of all the rest: for it was proportionable that the diuine part should haue the most perfect and absolute figure.

The defences
of the braine.

The defences of the braine are very many, the haire, the skinne and that the thickest of all the body, the fatte and fleshy Membrane, the *Pericranium*, the *Periostium*, a double tabled Scull and two Meninges or membranes, by all which it is of all sides defenced from violence, so that it cannot be hurt or offended but with extreame wrong. But neither the heart nor any other part is so provided for by Nature, wherefore it should seeme she made more store, as we say, of it then of all the rest.

The excellency
of the vse
of it.

In respect of the vse it will easily carry away the prize of Excellency; for the soule of

of man saith *Varolius*, being not tyed to any bodily instrument cannot apprehend those outward things which are without it selfe, vnlesse it be by the mediation of a corporeall organ, into which the *species* or formes of materiall things may be transmitted, by which afterward they may bee exhibited, and in which they may be apprehended and contemplated: euen as he that is shut vp in a roome, cannot see those things which are, or are acted without, vnlesse there be some Tralucēt body wherein the Images of those outward things may first be receiued and after represented to him that is within. Such an instrument is that which wee call *Commune sensorium* the common sence, for nothing can come into the vnderstanding vnlesse it be first in the sence.

Comparison.

Now this first or common sence according to *Plato* and *Galen* is the braine; (for *Aristotle* did but dreame that it was the heart) and they thought well. For not onely *Galen* but *Aristotle* himselfe did resolue, that that was the first *Sensorium* or common sence, which is the originall of sinewes. Nowe Anatomy teacheth vs that all the sinewes arise from the braine.

Arist. dreame.

The common sence is the braine.

Hence then it is manifest that the Braine is the seate of the Sensatiue Soule; for if a nerue which is directed vnto any part be obstructed, that part is deprived of sence and motion & so of the sensatiue Soule. If the originall or beginning of the spinall marrow be obstructed all the parts vnder the head do loose both sence and motion, when as yet the head inioyeth them both. But if the fourth ventricle of the Braine be obstructed, then not onely the whole bodie but the head it selfe looseth motion and sence, and is deprived of the sensatiue Soule.

Who then will deny that the Brayne is the most noble of all the members, seeing it is the seate of all the Animall faculties, Imagination, Reason or discourse & memory (wherefore *Aphrodiseus* called it *ὄργανον τῆς φρονήσεως* The Organ of wisdom) and the beginning or originall of sence and voluntary motion; and beside seeing from it doe vsue and on it do depend all the instruments of the senses of seeing, hearing, smelling, tasting, touching yea and speech also. And therefore *Plato* did worthily call it, because he could giue it no higher a stile, *The diuine Member*. For what the Heauen is in the worlde, the same in man is the Braine. The Heauen is the habitation of the supream Intelligence, that is, of God; and the Braine the seate of the Soule, that is, the *demi-God* of this little world.

Aphrodiseus.

Platoes.

Hence it was that *Homer* called it *ἱεραία*, that is the Heauen, because as from the Coelestiall influence all things below it are moued both in heauen and earth; so all the parts of the body haue sence and motion from the influence of the Braine.

Comparison.

Wherefore with *Galen* we determine that the Braine as well as the Heart is a principall part: not that wee thinke, as some doe, that the Braine is the Prince and King of the rest, no more then we thinke with *Aristotle* that the Heart is the most noble of all the parts. But we say that as the heart is of greatest & of most instant necessity for life, so the place of dignity belongeth to the Braine. *Columbus* giueth an elegant reason hereof taken from Generation.

The braine not the prince but a principall part.

The Liuer (saith he) is ingendred by the mediation and helpe of the vmbilicall veine, the heart by the mediation and helpe of the vmbilicall arteries, and these are ingendred by the vessels of the wombe: but the nerues which are the instruments of sence and motion doe immediatly arise out of the braine of the Infant.

Columbus, his reason.

The braine is commonly called *ἐγκεφαλος*. *Galen* in his Booke *de motu musculorum*, calleth it *κεφαλὴ ἐγκεφαλῆς* The marrow of the head, for a difference betweene it and the marrow of the backe which is called *ἐσχατὴς*, and the marrow of the bones from which it much differeth, because it is not dissolued by fire, nor consumed in hunger, nor contained in the skull to nourish it. Wherefore *Galen* in his 8. Booke *de vsu partium* and the 4. Chapter putteth a difference betweene it and the marrow of the bones, because this is fluxible and like vnto fat, neither couered with coates nor wouen with veines and arteries, neither hath any communion with the muscles and nerues, all which is contrary in the Braine.

The names of the braine.

Apollidorus thought that none of the Ancients had giuen any name to the Braine in any of their writings, and that therefore *Sophocles* called it *λευκὸν μυελόν*, the white marrow; imitating therein *Plato*, who when he would giue a name to the Brayne called it *κεφαλόν*, and True Loue the Grecians say is *ἐν τῷ ἀνωτέρω λευκὸν μυελόν*, euen at the uppermost marrow or at the Braine of the Soule, no doubt because they thought that the Soule was the Braine.

Sophocles

A greeke prouerbe.

It is scituate in the head as in a Castle most safe, because of the defences thereof before mentioned; as also because it is the highest place, & as it were the Tribunall or throne of

of

of her body. For as God who is the parent yea the Creator of the Vniuerse is sayd to haue his seate and throne in heauen: So the Braine which is the pallece of the soule was wiselie seated in the height of the body, partly also because of the eyes and eares, for their nernes being soft had neede also bee as short as might be, and therefore placed neere vnto the braine. Now aboute they must necessarily bee seated because they are the scout-watches of the Bodie to foresee and to heare of dangers before they come vpon vs.

Figure.

The Figure of the Braine is answerable to the Figure of the Scull, not that it is fashioned by the Scull, for if it had beene so, then the Scull should haue bin formed before the Braine. Againe (saith *Galen* in his 8. Booke of the vse of parts and the 12. chapter) they that say that the Braine is fashioned by the Scull doe not obserue that the Braine is manifestly separated from the *Dura Meninx*, and that the *Meninx* it selfe although it touch the scull yet it adhereth not vnto it. It expresseth indeede in the surface of it the forme of the cavitie of the scull, and when it is rightly formed it is round and a little longer then globous, because of the ventricles which were to be formed therein.

Forward it is somewhat narrower, backward broader, and on either side lightly depressed [Tab. 6, fig. 1. sheweth this] but in those that haue as wee say *Leisa principia*, that is, in Idots it is often otherwise fashioned as we haue said before. But in the Basis it is vnequall & full of variety because the scull hath there diuers dens and bosoms, especially at the wedge-bone [Tab. 14, Fig. 19, betweene A and the latter B] and the inward proceesse of the Temple-bones. [Tab. 15, Fig. 20, betweene H and N] But aboute all it swelleth out forward at the instruments of smelling, and produceth two teates as it were [Table 14, Fig. 19, CC] which are therefore commonly named *Mamillares processus*. But where it coucheth vpon the *Cerebellum* or after-braine it is smooth and more equall. [Tab. 14, Fig. 18, AA, BB.]

Magnitude.
Aristotle.

Concerning the magnitude; the braine of a man (saith *Aristotle* in his 2. Booke *de partibus Animalium* and the 7. chapter) in comparison and proportion with other creatures is the largest, so that the Braine of one man is more then of three Oxen, first because in a man there are many Animall functions which beasts haue not, and those that wee haue common with beasts are in vs much more perfect. For being in man the instrument and organ of reason, it was necessary it should containe yea and perfect also great plenty of spirits. Now many spirits cannot bee made but of much blood, and abundance of blood cannot be conteyned in a little body. Againe, it was fit that the braine should bee large, moist, thicke & glutinous that they might not by reason of their notable tenuity vanish away but passe into the whole body by proper and peculiar channels for them.

But the magnitude in length, breadth and thickenesse is so great as the capacity of the scull is able to containe, for together with his Membranes the Flegmaticke Glandule, and the vessels that ascend vnto it; it filleth all his compasse [Tab. 6, fig. 1, and 2. Table 9, fig. 3 and 4.] before and behind, and on either side, only leauing so much distance as may suffice for his *Diastole* and *Systole*. Finally, it is so great saith *Banhsine* that in our dissections we haue found it weigh foure or fve pounds; and *Archangelus* addeth fve pound and a halfe; for the larger a man is the greater and more weighty is his braine, yea children because of the waighe of their braine cannot of a long time carry their heads stedy vpon their shoulders.

Connexion.

It is knit by a common connexion of Veines, Arteries and Sinnewes with the rest of the parts, although more familiarly to the spinall marrow and the sinnewes, because they are produced heere from. Hence it is, that when the least or basest part of the body is pained the Braine also partaketh of the smart. As for supportation and strength it needed no assistance from the other parts because it is so strongly fortified and as it were intrenched within the scull.

Substance.
Archangelus.
Praxagoras.
Philosimus

The substance of the braine hath a double principle of which it is formed, the seede and the Mothers blood. *Archangelus* thinketh it hath no such principle, it may be hee is of the opinion of *Praxagoras* and *Philotimus* of whom *Galen* maketh mention in his 8. booke of the vse of parts and the 12. chapter, who thought that the braine was nothing else but a production or propagation of the spinall marrow, and that was the reason why it is foulded vp in so many convolutions and revolutions. But this is an idle speculation of a wandering Braine. We wil determine (as is said) that it hath a double principle, seede and blood, of which is generated a peculiar kinde of glandulous substance like whereunto there is none in the whole body, so that *Aristotle* exceeding well in his 2. Booke *de partibus Animalium* and the 7 chapter laide, that it was *sui generis* of his owne kinde, intimating thereby, that there was no other kinde in the whole body whereunto it might fitly bee referred. For because the in-

Aristotle

genit

genit functions of the Braine are peculiar vnto it alone as *Vesalius* hath well obserued, it was framed and fitted by Nature for the performance of these functions, of a peculiar substance and essentiall forme wherein the principall faculties of the soule, Iudgement, Imagination, Reason and Memory might reside, and which they might vse as their proper instrument, and on which the rest of the senses might depend.

It is white, soft and very moist. White by reason of his spermaticall matter, for it is made of the purest part of the seede furnished with abundance of spirits, as also that the Animall spirits therein contained should bee cleare and bright, not muddy or otherwise coloured. Yet is not all his substance perfectly white, for that which is neerer to the convolutions [tab. 9. fig. 4. tab. 10. fig. 5 E F] is somewhat nearer to an Ash colour, as it is also in the *Cerebellum*, the reason whereof some think to be because there are so many small veines disseminated through it. For as we thinke the *via lactea* or Milky Way in heauen is occasioned by an infinite number of small starres which to vs are inuisible, but yet do giue a brightness to that part of the sky; so though we cannot see how the veines do alter the colour in this place, yet seeing it is altered, it is very reasonable that the insensible membranes of the small veines giue that ashy colour vnto it. The rest of the Braine a little more inward is pure white [tab. 9. fig. 4. G H. tab. 10. fig. 4. G H. tab. 11. fig. 7. and 8. E E.]

It is soft, and softer (saith *Galen* in his 8. Book *de usu partium* and the sixt Chapter) then the *Cerebellum*, because it is the originall of the soft Nerves pertaining to the Organes of sense, but the *Cerebellum* is the originall of the hard Nerves commonly thought to bee the Nerves of motion. In Children the Brain is so soft that it is fluid. The reason of the softnes is because it is to receiue all the species or representations of the outward senses, as also of the imagination and vnderstanding. For vnlesse the alteration or impression that is made in any of the senses do proceede first from the Braine and after returne againe vnto it, the creature hath sense of nothing; which is proued by the example of such as are taken with the Apoplexie. Wherefore seeing sensation is a passion, it was requisite that the braine should be of such a substance as is fit to receiue the impressions of such things. Yet it behooued not it should be so soft as that the impressions made therein, should presently sink away and be obliterated, as it hapneth in water and other fluide bodies, but that it should haue with the softnes a kind of consistence or solidity, which solidity is so exquisitely mingled with the softnes, that the fire cannot melt it as it doeth fat or wax and such like. To conclude it is like the substance of a nerue, of which also his marrow is the originall, but a little softer. *Hippocrates* in his Book *de Glandulis* liketh it vnto a kernell, because as a kernell it is white and friable, and beside is of the same vse to the head that a glandule would be, drawing vp the exhalations of the lower parts which after vapor out by the Sutures of the skull.

The Temperament of the brayne is cold and moist, as we may easily with *Galen* in the 8. Booke of the *Vse of parts* conclude from the softnes and moistnes of his substance. Wherefore *Hippocrates* in his Booke *de Carnibus*, calleth it *μυρροειδὲς καὶ ὑγρὸν καὶ τὸ κολλώδες* the *Metropolis* or chiefe seate of cold and glutinous moisture. Glutinous to hold and containe the subtile Animall spirits which otherwise would soone vanish and decay; and cold that the part ordained for the exercise of reason and therefore fulfilled with hot spirits should not easily be set on fire or enflamed. For when the braine by any accident or distemper growes hot as we see in phreniticall patients, the motions thereof are furious and raging, and the sleep or none, or turbulent and vnquiet. And indeed the Head is very subiect (colde although it be by Nature) to hot distempers, partly because of the perpetuall motion thereof and of the spirits, partly by reason of the aboundant Veines and Arteries and great quantity of blood therein conteyned, and finally because whatsoever hot thing is in the body either Naturall or vnnaturall if it be inordinately moued flieth vp vnto the braine, or at least senderth hot vapors vnto it.

CHAP. XI.

Of the Substance and parts of the Braine.

As the Braine is the Originall and seate of all the Animall Faculties, so for the exercise of the same it hath diuerse and different parts cast into sundry moulds which we will now take view of according to Anatomical Method, alwayes remembring that

R r

Vesalius.

The Reason thereof.

Why the brain hath diuerse parts.

that by the Braine we vnderstand whatsoeuer is conteyned within the Scull and compassed about by the hard and thin Membranes.

3: Parts.

The Braine therefore we deuide into three parts. For first it is parted into a fore-part and a hind-part by the *Dura meninx quadruplicated* or foure-foulded.

The forepart.

The forepart because it is the greater and most principall (for in it the Animall spirits are especially laboured) reteineth the name of the whole, and is properly called *Cerebrum*, or *ἐγκεφαλον*. The hinder part is much lesser, and is called by a diminutive word, *Cerebellum* we call it the After-braine. *Herophilus* as *Galen* witnesseth in his 8. Booke of the *Vse of parts*, and the 11. Chapter; calleth it *παρεγκεφαλον*.

Subdiuided.

Againe the forepart or the Braine, by the *dura meninx* duplicated and resembling a Mowers Sythe, is parted in the top throughout his whole length into two equall parts, one right, another left. [tab. 8. fig. 2. from A to A. tab. 9. fig. 3. from N to R.]

This partition reacheth altogether to the Center of the Braine and stayeth at that body which we call *Corpus callosum*. [tab. 9. fig. 3. at L L.] And this is the reason why alwayes the same part of the head is not pained, but sometimes one part sometimes another, sometimes the whole head.

Some, sayth *Laurentius*, haue dreamed that the braine is deuided quite through, but they are much deceiued, for the callous body vnitheth the parts together. As for the after-braine though it bee not vnited to the braine, yet is it in two places continued with the beginning of the spinall marrow, and the same marrow by two originalles ioyned vnto the Braine.

The vse of this diuision.
Out of *Vesalius*.

The vse of the diuision of the Braine is first out of *Vesalius* and *Archangelus*, that the brain might bee better nourished, for by this meanes the thinne membrane together with the vessels there-through conuayed, doe insinuate themselves deeper into the substance thereof: for without this partition and those deep conuolutions which we see in it when it is cut it could not haue beene nourished.

Out of *Laurentius*.

The second vse we will adde out of *Laurentius*, to wit, beside the nourishment for the better motion of the same; for as water is not so easily mooued where it is deep as where it is shallow; so if the braine had beene one entire massie substance, it would not so willingly and gladly as we say, haue risen and falne in the *Systole* and *Diastole*.

Out of *Banbini*.

The vse of this diuision out of *Banbini* is more expresse: for the safe conduct of the *Sinus* or pipes of the hard *meninx* mentioned in the seauenth Chapter, from whence doe issue small furcles of vessels to conuay nourishment into the conuolutions of the braine.

For because the quantity of the braine is very great, through which the *Capillary* vessels were to be disperfed for his nourishment; if the vessels themselves so small as they are veines & arteries, should haue passed from the backpart to the forepart, from the right side to the left or on the contrary, they would in so long a iourney through so soft and clammy a body haue been in danger of breaking, wherfore the braine was diuided into three parts; betweene which diuisions there runne foure *Sinus* or pipes of the hard *meninx* into which the internall Iugular veines and the sleepey arteries called *Carotides* ascending from the *Basis* of the Nowle of the head doe powre their bloud and spirits; which is conuayed on either hand into the after-braine and the braine, by certaine branches deriued out of height and depth and the sides of those pipes as we sayd ere-while, especially out of the third *Sinus*, into the left, and right parts of the braine.

Finally, because soft bodies when they are great doe easily fall into themselves, therefore the brain was diuided into two parts that it might the better consist, as also that the instruments and organs which were led vnto it might not be shuffed together: and so much of the vses of the diuision of the braine.

The conuolutions of the braine.

Now the outward face of the braine which we sayd was of an Ash-colour rather then white, hath many and diuers orbicular circumuolutions and circular ruts, which the Ancients sayeth *Vesalius* and those after him haue excellently compared to the gired windings of the guts when the kell is taken off. [tab. 8. fig. 2. tab. 9. fig. 3. c c c.] *Galen* in his 8. Booke of the *Vse of parts* and the 13. Chapter calleth this *variā compositionem*, and *Vesalius* himselfe compareth them to the Clouds that a Painter makes in the rooffe of a house. Some of these snailing paths are deeper, others do not pierce so deep into the substance of the braine [tab. 9. fig. 4. DD] & therefore are called *pars varicosa cerebri*, the knotted or embossed part of the braine by *Laurentius*. They are inuested with the *pia mater* or thin *meninx* (and when that is taken off may be better discerned) which not only compasseth them and containeth them

in

II.

in their superficies, but also with the in many places diueth into the depth of the braine.

Some are of opinion that these conuolutions are only framed of necessity, but haue no vse at all: but we with *Galen* do determine that their vse is to secure the vessels, that going together with the *Pia mater* they might cary vnto the brain nourishment and life, and not be in danger of breaking in the perpetual motion and agitation of the braine. For the *Pia mater* being a thin and fine membrane and simple (not double that the vessels might run betwixt the duplication thereof) needed these winding Meanders to secure the vessels.

But if the superficies or surface of the braine had beene smooth & equall & the vessels had run along about the circumference thereof, they had beene subiect to breaking, especially in the *Diafoe* or Eleuation & in the full of the Moone, at which time the braine by reason of the humidity thereof so swelleth that the vessels must needs haue borne vpon the scull. Beside, the vessels would not haue beene sufficient to haue irrigated and watered the huge

and vast body and bulke of the braine if they had onely runne ouer the surface thereof. *Platerus* addeth further; because the venall and arteriall blood arising to the braine is not yet fit for the vse thereof, it was necessary it should runne in proper vessels, and that into the inmost substance of his marrow where the inbred power of the braine might labour it and purge it from those excrements which are gathered and heaped vp in these Conuolutions, that being so prepared the braine might apply it as vnto his nourishment and also for the procreation of Animall spirits.

Another vse of the Conuolutions remembred also beside *Bauhine* by *Archangelus* and *Laurentius* is, for the recreation of the spirits and the blood contained in those vessels. For if there had not beene these gyrations in the substance of the braine, the vessels especially in the full of the Moone would haue beene so closely compassed by the Scull, that their motion would haue beene intercepted, and the spirit being compressed would haue beene suffocated or strangled, and the heate for want of ventilation extinguished.

Erasistratus thought that the braine of a man had more Conuolutions then the braines of other Creatures because of his reasonable soule; which conceite of his *Bauhine*, *Archangelus* and *Laurentius* do sweetly smile at, when they behold the same conuolutions in the braine of an Asse, the most dull and stupid of all other creatures. Beside we learne out of *Galen* in his 8. Booke of the *Vse of parts* and the 13. Chapter, that vnderstanding followeth not the variety of the composition but the good temper and disposition of that body which vnderstandeth. *Laurentius* and *Columbus* thinke that Nature by these conuolutions provided for the lightnesse of the braine, and to make it more prompt and ready for motion. But *Archangelus* taxeth them for it. As if (saith he) Nature could not haue made it of a lighter

FIG. IV.

- AA, The right side of the Braine.
 BB, The left side of the Braine.
 CC, The convolutions or breaches of the Braine.
 DD, The duplication or proesse of the *dura mater* called the Sythe.
 EEE, The beginning of the vessels proceeding out of the third *Sinus* into the thin membrane are heere broken off.
 F, A passage running out of the fourth *Sinus* in manner of a veine into the lower part of the thicke membrane.
 GG, Certaine propagations of this passage running vpward into the same membrane.
 HH, Certaine Surcles disseminated from the lower side of the third *Sinus* into the proesse.
 II, The beginnings of the vessels which passe from the fourth *Sinus* into the thin Membrane.
 K, The beginning of a vessell bred out of the fourth *Sinus*, which runneth vnder the arch into the third ventricle to make the *Plexus* or thrumbe of crisped vessels therein.
 LL, The Callous body of the braine.
 MM, The *Sinus* on eyther hand, at the sides of the Callous body.
 N, A portion of the Sythe which groweth to the partition of the Organe of smelling.
 OO, The thin membrane or *Pia mater*.
 PP, Parts of the thicke membrane reflected.

Fig. 4.

- AAA, BBB, The right and the left sides of the marrow of the braine remaining yet in the Scull.
 CCC, A part of the braine taken away.
 DDD, Divisions or lines from the breaches of the braine.
 EEEE, The Shel or Barke of the braine compassing his marrow.
 GG, HH, The marrow of the braine which when it is pressed is full of red points or small drops or graines.

III, The Callous body freed on either side from the substance of the braine. KK, A part of the Callous body. LL, MM, The right and the left ventricle of the braine. NN, a part of the vpper side of the left ventricle. OO, The complication or thrumbe of vessels called *Plexus Choroideus*. PP, Small veines growing to the ventricles. Q, Other vessels running from the same veines into the *Pia mater* or thin membrane.

matter if that had beene behouuefull, or a little lesse and so lighter? Beside wee see that the heart is of a most solid and firme substance without any of these gyrations, and yet it mooueth in *Systole* and *Diastole* very freely. *Vesalius* and *Laurentius* adde that they were also ordained for the supportation of the soft substance of the braine that it might equally be supported and not sway too much to either side. And thus much for the vses of these convolutions as also for the vpper part of the substance of the braine.

Now the internall or inward superficies hath in it diuers parts and impressions because of the many vses for which Nature hath ordained it. The substance therefore of the Braine is by *Archangelus* diuided into the Braine and the Marrow. The Braine he calleth that ash-coloured part which compasseth the rest, whereby he meaneth the marrow: we will say it may be diuided into the Shell and the Kernell. The Shell is that Ash-coloured body [tab. 9 fig. 4, tab. 10. fig. 5, EF] which compasseth immediately the kernel or marrow. The kernel

or marrow is that white body [*tab. 9. fig. 4, G H, tab. 10. fig. 5, G H, tab. 11. fig. 7, and 8, E E*] which is hid within the ash-coloured body and is somewhat more solide; for this white body is within the ash-coloured body as the cristalline humour of the eye is in the glassie humor. Wherefore the shell differeth from the kernell first in color, the one ash-coloured the other white; then in consistence for the shell is softer the kernell a little harder firmer and more compact; then in scituation because the kernell is in the midst the shell in the circumference distinguished with oblique and crooked lines.

Wherefore the kernel or Marrow is the middle and white body of the braine, of which there are two parts; one containd within the skull, the other falling out of it and lengthned downe to the great hole of the *occiput* and ending in the spine of the backe. These two bodies also, the shell and the kernel, may actually be separated if we haue the head of a sound man new flaine and presently with dexterity dissected; otherwise both of them will grow very moyst and extreame soft, as it hapneth to the mammillary processes which are the instruments of smelling, which in a fresh body may easily bee parted at the marrow, but not so if the body haue beene dead any time.

Now if you dissect the braine ouerthwart, about the midst of it you shall perceiue small vessels therein descending to his ventricles, and if the marrowey substance be pressed there will start out of it many drops or graines of blood, which make me remember that of *Hippocrates* in his Booke of the falling sicknesse. *Many and small veines doe ascend out of the whole body vnto the braine, and especially two notable, one from the Liver another from the Spleene:* in the quest of which (if any such be) I would haue the great Anatomistes spend some of their curious howres.

Aristotle in the first Booke of his History and the 16. Chapter is of opinion, that the braine is altogether without blood (that we finde false by manifest experience) neither containeth any veine within it, but that onely the Meninx about it hath veines. *Vesalius* leaneth too neare vnto him, for these are his words: The substance of the Braine and After-braine is neuer found with any veines therein, although you shall find in those that dy mad or phreneticall and such as are hanged, certaine red and bloody specks or spots; but these spottes carry no resemblance of a veine at all. Notwithstanding, though these two great Clarkes, the one the Genius of Nature and the very President of her priuy Councell and the other the Eye of Anatomie, haue thus resolved vpon the case: I presume there is something in that *Hippocrates* hath so particularly related, whose vse is not so peremptorily to seduce his Reader: but I leaue the disquisition to those whose meanes and oportunities are fit for such priuy searches, onely adding this one thing which I confidently auouch, that the onely writings of *Hippocrates* after so many ages and Commentaries past, haue in these dayes led the diligent and studious Readers into the knowledge of more mysteries of our Art, then all the writers in the world beside; for hee alone is a boundlesse and bottomles ocean of Physicke: we returne to our history.

If you lightly with your fingers deuide the sides of the braine till you come to a veine of a notable bignesse running through his length and sprinckling branches on either hand into the braine, there will offer it selfe vnto your view a body placed exactly in the midst of the braine [*tab. 9. fig. 3. L M*] gibbous or rising somewhat round [*tab. 9. fig. 3. L*] in which sayeth *Archangelus* the two first ventricles are excauated, long, narrow, smooth and equall, whiter also then the vpper part as being made of the marrow or inward substance, which because it is harder and somewhat like a callous or hardnesse of the skinne gotten by labour but much whiter, is called *τὸ λεγόμενον*, by *Galen* in the 9. Booke of his Anatomicall Administrations and the third Chapter, that is, *A callous body*. It is a part continued with the braine, wherefore at the sides thereof in his length two *Sinus* or ventricles [*table 9, figure 3. at M*] are hollowed in the marrow of the braine like deep lines or hollow pipes, which are esteemed to receiue the defluxion, of rheume, or phlegme out of the vpper parts of the braine, and to send it forward by the gibbous superficies of the callous body vnto the nose. But the vse of the callous body vndoubtedly is by his vpper part to sustaine the waight of the braine which lieth vpon it, and that by this mediation both parts of the braine might be conioyned, as also to make a distinction or hedge which they call *septum* [*tab. 10. fig. 5, R R* holdeth vp *T T, X X* and *X T* lift up *S T V*, least *A A A* in the sixt figure should presse *H I* in the same figure or *H* in the 7, and 8. figures of the 11. Tab.] which separateth the two ventricles; which partition it also sustaineth and lifteth vp the arch called *Fornix*, least falling downe it should compress the third ventricle.

The vse of it.

A story out of
Bauhine.

In this place sayth *Bauhine*, in the year 1582. I found a scirrhus or hard tumor in the noble Baron *Bonacurtius* (who lay a long time in a manner Apoplectical or astonished) when we opened his head after his death.

When we haue cut away the substance of the braine on either hand as deepe as vnto the Callous body, before we list it vp, we must marke the *septum* or partition of the two first ventricles.

The *septum*
lucidum.

This *septum* or partition [*tab. 10. fig. 5. at R R R reflected backward*] in the vpper part groweth to the Callous body and is perfectly vnited thereto (wherefore *Vesalius* calleth it the inner or lower *superficies* of that callous body) but below it groweth to the place of the Arch or *Fornix*, so that it standeth in the middest betweene the callous body and the Arch. This *septum* before it be stretched is loose and rugous and doeth not shine, neither can you perceiue how it is continued with those bodies of the *Callus* and the Arch; but drawe it vp so high till it be stretched (and take heed it breake not for it is but thinne) and then if you put a waxe candle to one side of it you shall perceiue the brightnesse of the light through it as if it were through a glasse. *Vesalius* compares it to the host in the Masse, which being a thinne wafer and a little wet, you may see a dull light through it; or say it is like a sliuer of the Muscouy glasse whereof we vse to make Lanthorns, or the horne of a lantorne it selfe. Whereupon *Columbus*, *Archangelus* and *Laurentius* haue called it *speculum*, *speculum lucidum*, *septum lucidum* and *lapis specularis*, the Looking-glasse. *Galen* giueth it a name from his vse in his 9. Booke *De Anatomicis Administrationi*, the first, the third and the fourth Chapters, calling it διαφραγμα των προσθιων κελων, The partition of the foremost ventricles, because the inner lips of the ventricles are hereby distinguished; wherefore you cannot aright perceiue it vnlesse both the ventricles be layd open, and if it be neuer so little too much stretched it easily breaketh, because it is so very thinne and subtile, yet cannot it be manifestly seene vnlesse it be lifted vp.

Archangelus.

An Anatomist therefore in these curious things had neede to haue a fine and a dainty hand and at command. This partition is of the same substance (sayth *Galen* in the Booke before named and the third Chapter, and after him *Vesalius*) with the braine, but thinner, and in respect of his tenuity as it were the substance of the braine drawn out into a membrane. *Columbus* and *Archangelus* thinke it is nothing else then the *pia mater* in this place duplicated; but *Laurentius* and *Bauhine* agree with *Galen*. Yet though it bee thinne it is not simple, and it hath in the middest a little rising like a line [*table 10. figure 5. r*] which line bearing downward is by degrees lessened and becommeth the partition of the ventricle. [*table 10. fig. 5, the lower part of the septum at x x, the vpper at T.*]

These ventricles beeing taken away to the middest of their substance, wee meete with foure swelling particles: two before, about which is the Basis of the ventricles, two on the backside making the Arch or *Fornix*, of which we will entreate in the next Chapter.

CHAP. XI.

Of the ventricles of the Braine, the Arch, and the Plexus Choroides.

The ventricles
of the braine.

Although the Cavity which is in the Braine be continued quite through, yet because according to the forme of the Braine and the vse it is diuerly formed, so that one part is more dilated another more angustated or contracted; therefore the Anatomists haue diuided it into certaine places, and the larger of them they call ventricles, the narrower they call *meatus* or passages. The ventricles called by *Galen* κελιας, the Ancients and many of the new writers also following therein *Herophylus* haue reckoned foure. In the Braine three; two forward a right and a left, and the third in the middest. The fourth they make common to the after-braine and spinall marrow.

The first two of these (called by *Archangelus* the *Superior* because they hang ouer the other; by *Galen* in his 8. Booke of the *Vse of parts* the 10, 11, and 12. Chapters and diuers other places, the *Anterior* ventricles) are cut out of the marrow of the braine and are the largest of all the rest, because (saith *Laurentius*) they containe a crasse spirit or rather abundance of phlegme. They are on either side one, the right on the right hand and the left on the left, alike each to other in scituation, forme, magnitude and vse. They are scituate length-wise in the marrow of the braine in the very middest thereof. [*tab. 9. fig. 4. table 10. fig.*

fig. 5, L. fig. 6, the right is noted with D, but the left in the 9. tab. and the 4. fig. and the 10. tab. and first fig. at M, in the 6. figure at E] whether you respect the length or the depth of it. In their fore and hinder parts they are broader and more disioyned, in the midst lesse where they are onely divided by that thin partition we spake of in the former Chapter. [tab. 10, fig. 5. XXX] They runne obliquely or semicircularly saith *Archangelus*, [tab. 9. fig. 4, from L to M] for beginning about the temples where the marrow begins, they are by little and little curved toward the center of the marrow, and at the Region of the Eares they are bent againe, and so seeme to make two Semicircles. They are long, winding and somewhat large. Their forepart is blunt and round [table 9. fig. 4, and tab. 10. figure 5, L and the lower M] and in their inside they sinke downe vnto the third ventricle, [tab. 10. fig. 5, vnder STV and in the 6. fig. at H and I, the eleuenth table and the 7. fig. at H] whereupon some who have not diligently followed their curued passage haue thought that beside these two there are other two ventricles in the forepart of the braine, and so haue made vp the number of sixe ventricles; but we esteeme them to be portions of these vpper, for they are indeed larger then vsually they are esteemed. Backward also they are obtuse and round, [tab. 9. fig. 4, the vpper L and M] and do descend by degrees downward into the substance of the braine, and forward are straightened like the small end of a horne, and so creepe on to the mammillary proccesses and the ingresse of the opticke Nerues [tab. 11, figure 7, and 8. FG] and the sleepey arteries. Their vpper face is lined with a waterish moysture, and they are often found full thereof. Their vpper part [tab. 9. fig. 4, from L to L and from N to N] according to the length of the braine is smooth and æquall; the lower part is vnæquall, [tab. 10. fig. 6, R or S] because of the hollownesse prepared to receiue the defluxion of the phlegme; which hollownesse creepeth obliquely out of the backpart of the ventricles forward into their common cavity. For these two ventricles, as we shall say by and by, do determine into a common cavity. *Galen* and the ancients after him do write that the superficies of the first three ventricles are as the braine couered with the *Pia mater*. *Vesalius* denyeth it and addeth a reason: for, saith he, if the ventricles were lined within, the Membranes would hinder the substance of the braine from working the matter conueyed into them into Animall spirits. But *Columbus* and *Archangelus* side with *Galen* against him, and *Archangelus* thinketh that the *septum lucidum* is made of the duplication of the *Pia mater* after it hath inuested these ventricles. Wee leaue this to be farther scanned by the curious Dissectors: sure wee are that that which is called *Plexus Choroides* lyeth vpon them, from whence small veines [table 9. fig. 4, PP. tab. 10. fig. 5, PP. fig. 6, OO] are deriued which grow in the forepart to their substance, like vnto those which runne through the coate of the eye called *Tunica Adnata* or the white of the eye. *Archangelus* is of opinion that the *Pia mater* being it selfe of exquisite sense may by meanes of these small veines suffer inflammation, whence come those deepe paines which are sometimes felt in the Center of the braine. And indeed *Galen* maketh expresse mention both of the *Pia mater* compassing their cavity as we haue saide before, as also of these veines which insinuate themselues into the ventricles in the second and third Chapters of the 9. Booke of his Anatomical Administrations: so that *Archangelus* doeth but gather the conclusions out of *Galen*s præmisses.

It behooued sayeth *Galen* in the 8. Booke of the *Vse of Parts* and the 10. Chapter, that there should bee two of these ventricles, (because the Braine and euery organe of sense is double; for the braine is the first and most common cause of all those double organs) that if one of them be violated, the other might serue the turne; and this hee prooueth by an instance of a young man of *Smyrna*, who was wounded into one of these ventricles and yet escaped: but sayth he, if both of them had beene wounded he could not haue liued a moment of time.

Vesalius (as he is an importunate aduersary of *Galen*s, the lesse his thanke) reprobeth him for this, alledging that though the braine be parted into two, yet it is againe vnited before the ventricles are formed therein; and to say trueth it is hard to conceiue how one ventricle should bee wounded and the other not violated, considering the thinnesse of the membrane or partition that parteth them, and beside the common cavity whereinto they both determine; but experience often assureth vs of that which meere Reason and discourse will not allow of or subscribe vnto.

The vse of these ventricles is according to *Galen* in his eight Booke of the *Vse of Parts* Chap. 10. and 11. that of the ayre which we draw in conuayed into the brain by the organs of smelling & of the vital spirit ascending from the heart by the sleepey arteries, the Animal

*The two paſ-
ſages thereof*

The firſt

ſpirits prepared before in *plexu choroide* might in thoſe ventricles bee perfected, but how perfected? *Vesalius* thinketh by the particular ſubſtance and forme of the Braine. *Archangelus* thinketh they haue no ſuch uſe or power as to make Animall ſpirits. *Laurentius* ſayth that they ſerue for the inſpiration and expiration of the Braine, to receiue ſmells and to prepare the Animall ſpirits, and to containe them as it were in a ſtore-houſe yet not perfectly accompliſhed but inchoated onely. *Archangelus* ſubſcribeth vnto this and addeth moreouer, that the ayre drawne through the noſe and ſpongy bone into the ventricles, is laboured and prepared for the nourishment and refection of the Animall ſpirits, as the ayre is prepared in the Lungs for the refrigeration and recreation of the vitall ſpirits. Another uſe ſayeth he of them is (but that onely a ſecundary uſe) to ſerue for wayes whereby the excrements of the braine may be purged. Neither ſayth he, is there cauſe why we ſhould wonder that the ſame ventricles ſhould holde the Animall ſpirits and ſerue alſo for the ablegation of excrements, ſeeing we know that Nature hath ordained the Noſe firſt and primarily to be a meanes of ſmelling, and ſecondarily to call out the phlegme out of the braine and auoide the ſame.

We ſayeth *Bauhine* thinke, they ſerue to gather the excrements which are ſeparated in the nourishment of the Braine, the phlegme (for example) there engendred, and by their common paſſage to ſend it into the Tunnell called *Infundibulum* to bee conuayed away by the throat.

Archangelus in this place maketh mention of a paſſage which is (ſayth he) in the middeſt vnder the mammillary proceſſes & hath a double iſſue, one directly into the ventricles we ſpeake of, the other into the pallate and ſo into the Lungs. This paſſage is knowne but to a few, neither can it be found but in a ſound Braine when the man commeth to a ſudden and vnlooked for end and is preſently diſſected; for the parts of the braine that are about this paſſage do in a ſhort time ſo fall and cloſe together that the paſſage is cleane obliterated.

Hence *Galen* in his 8. Booke of the *Uſe of parts* and the 10. Chapter ſayed, that the ayre we breath in by our noſes paſſeth vnto the heart, but a part of it getteth into the ventricles where it is prepared and made the nourishment of the Animall ſpirits. *Columbus* aſcribeth the finding out of this paſſage to himſelfe, but *Archangelus* taxeth him therefore. And ſo much of the two firſt ventricles.

The third ventricle followeth, which is nothing elſe but the concurrence or meeting of the two former lengthned out ſomewhat backward. For the two former ventricles in their lower part vnder the Arch [*tab. 10, fig. 5. STV*] [*fig. 6. AAA*] do meete together in one place and there determine, being in their neather parts like a narrow path which runneth out backward a pretty length into the hindmoſt ventricle. This is called by *Galen* in his 8. Booke of the *Uſe of parts* and the 12. Chapter, the common cauity or common place of the forward ventricles; [*tab. 10, fig. 6, vnder H 1, tab. 11, fig. 7, and 8. H*] by others who doe deny the third ventricle it is called the perforation of the two former ventricles: others call it the third ventricle or the middle ventricle, becauſe it is in the middeſt of the braine, yea and in the very Center of the marrow betwixt the two forward ventricles and the fourth.

This at the firſt ſight is like a long ſlit or cauity, [*Tab. 11. fig. 7, and 8. H*] but more backward it becommeth larger, and is diſcerned, part of it when the arch is drawne a little backward, part of it when the Teſticles and the Buttocks of the braine are diuided in the midſt. It tendeth directly from the forward ventricles vnder the arch, the teſticles and the buttocks, [*Tab. 12, Fig. 10, from I to K*] toward the fourth ventricle [*Tab. 12, Fig. 10, K ſheweth the end of it.*] And this is *Galen's* delineation of his paſſage in his 8. Booke of the *Uſe of parts* and the 11. Chapter, whereunto *Vesalius*, *Platerus*, *Archangelus* and *Laurentius* do ſubſcribe, but *Columbus* maketh it ſhorter and ſayth it endeth at the backward paſſage neare to the *Glandula pinealis*. The figure of it ſayeth *Archangelus* is vncertaine becauſe there are many eminencies or inequalities in it.

This third ventricle hath two paſſages, of both which *Galen* maketh mention in his 9. Booke of Anatomicall Adminiſtrations and the fourth Chapter, the one he calleth the vpper hole or the Tunnell, the other the great hole of the third ventricle, wee according to *Bauhine* will deſcribe them thus.

The one [*Tab. 11, figure 7, and 8. I*] proceedeth out of the middeſt of the ventricle and is reaſonable large: it is caued in the ſubſtance of the braine and runneth directly downward

toward the *Bafon* which receiveth the phlegme at the Basis of the braine, and by it the phlegme of the two forward ventricles doth descend.

The other passage [*tab. 11, fig. 7, and 8, K*] which is the more backward (*Laurentius* addeth the larger also) is not round in his originall although it be a part of the third ventricle which is round. *Galen* in the 9. Booke of his Anatomicall Administrations and the 5. Chapter, thinketh that it hath a peculiar coate like that of the *Pia mater* wherewith it is lyned. It runneth vnder the Buttocks [*tab. 11, fig. 7, MN, fig. 8, NOPQ, tab. 12, fig. 19, DEFG*] and the Testicles into the fourth ventricle about the beginning of the spinall marrow. Out of the lower and forward angle of this passage, as soone as it is gotten vnder the testicles, there issueth another passage, [*tab. 11, fig. 8, neare to K*] farre narrower then the former, which passing sliely forward through the substance of the braine, sinketh downward and determineth in the end [*table 11, fig. 1*] of the first passage; out of both which ariseth an orifice [*tab. 15, fig. 20, D*] which endeth in the *Bafon*, and leadeth the phlegme out of the third ventricle. This *Vesalius* taxeth *Galen* for pretermittting, in the place next above named. Now whereas at the second passage there appeareth a certaine slitte or cleft, *Columbus* will needs liken the same vnto the lap or priuity of a woman.

The vse of the third ventricle is to be a receptacle of the Animall spirit, which also is by Nature so quainly formed (for *Archangelus* referreth all those resemblances of the Arch, the buttocks, the testicles, the fundament, the womans lap and the yard vnto the third ventricle) that it driueth them into the fourth ventricle.

About this third ventricle lyeth the *Fornix* or Arch called *καμάριον καὶ ἀλλοειδές*, because in forme and vse it resemblenth a crosse vault or arch. *Columbus* calleth it *Corpus cameratum*. The vaulted body, which (saith he) is supported with 3. pillars. This arch is but one and lyeth vnder the Callous body almost in the middle of the braine but a little backward, and swelleth equally out of both sides thereof: for it is common to both sides of the braine. It groweth out of the backe part of the two vpper ventricles [*tab. 9, fig. 4, the vpper L M. tab. 10, fig. 5, ST, fig. 6, BC*] where they bow forward. Whilest it is containd within the brain it is a long and callous body, yet broader toward the back-part, but as it creepeth forward it groweth sharpe to his very end, [*tab. 10, fig. 5, from ST to V, fig. 6, from BC to the vpper A.*] At that forward sharpe end [*tab. 10, fig. 6, at P*] it is againe ioyned to the substance of the braine as also to the callous body; but in the middest and in the rest of his bredth it is free and at liberty [*tab. 10, fig. 5, XX.*]

The figure of it is Triangular but consisting of vnequall sides, so sayth *Galen* in his eight Book of the *Vse of parts* and the 11. Chapter. *Vesalius* and *Laurentius* call it *semicircular*, or rather like a bridge whose backpart standeth vpon two knees, the forward vpon one. For first in the backpart it reacheth from one of the ventricles ouer to the other, and that side is short [*tab. 10, fig. 5, from S to T, and fig. 6, from B to D.*] The two other sides are equall and somewhat longer, reaching from the backpart to the forepart [*tab. 10, fig. 5, from S to V, and from T to V, fig. 6, from B to the vpper A, and from C to the vpper A*] so that backward it hath two Arches and forward one, and standeth like a threefooted stoole vpon the braine.

The substance of it is like the substance of the ventricles but somewhat whiter and harder, like the substance of the callous body. It is no where compassed with the *pia mater*, and in the bottome where it archeth ouer the ventricle, it is free and at liberty not tyed to any of the adjacent parts. [*tab. 10, fig. 6, A A A.*] In the sides where it respecteth the two forward ventricles [*tab. 10, fig. 5, at L M.*] it is supported, backward with two props and foreward with one; the superficies of it is smooth and moystned with a waterish humor.

On the outside neare the originall it is gibbous, embowed [*tab. 10, fig. 5, ST*] or convex, and in the originall orbicular or round, that without payne (sayth *Galen* in the 8. *de vsu partium* and the 11.) or disease it might sustain the waight of the braine lying vpon it, that the common passage or third ventricle vpon which it coucheth, might be kept open and large and not compressed, because vnder it the two first ventricles do meete.

In the length of it it swelleth a little in the middest like a broade line [*tab. 10, fig. 5, XX*] by which it is continued with the partition of the ventricle called *septum lucidum*.

Within it is hollow [*table 10, fig. 6, A A*] as well for the free passage of the spirits, as also that the vessell [*table 10, figure 6, HI, table 11, figure 7, V, arising from T*] arising out of the fourth *Sinus* of the *Dura mater* and diuided into the two forward ventricles, might passe vnder it and not be pressed by the substance of the braine hanging ouer it. And thus much of the Arch.

Substance.

The

Table 10. Figure 5. sheweth the same that the former Table did, saving that the Callous body in the foreside separated from the Braine and reflected backward, and torne from that partition which distinguisheth the ventricles, is heere more manifestly to be perceived, together with the Fornix or Arch of the Braine.

Figure 6. sheweth the Arch loosned on the foreside and drawne backward, that the lower part and the vessels might better be seene.

TABVLA.X.

Figure 5.
RRR, The lower superficies of the callous body reflected.

STV, The triangular surface of the Fornix or Arch.

XX, The lower part of the partition of the ventricles continued with the Arch.

YY, The upper part of the partition continued with the callous body.

Figure 6.

AAA, The lower surface of the Arch.

BC, Two corners of the Arch by which it is continued with the ventricles.

DE, The right and left ventricles.

FG, Arteries climbing vp from the sleepy arteries thorough the lower side of the ventricles for the forming of that complication of vessels which is called *Plexus choroides*.

H, A vessell issuing out of the 4. Sinus under the Arch, and passing into the third ventricle.

IKL, The diuision of this vessell, a part whereof goeth to the right ventricle at K and another to the left at L.

MN, The *Plexus choroides* made of the artery FG, and the vessell H.

OO, Small veins passing thorough the ventricles of the braine produced from the vessels K and L.

P, Other veins arising from the same, dispersed without the ventricles into the *Pia mater*.

Q, A passage from the third ventricle vnto the *Basin or Tunnell*.

RS, Canales or Sinus grauen or furrowed in the substance of the ventricles in which the phlegme is led along to the orifice of the foresaid passage marked with Q.

The *Plexus Choroides*.
The names.

What it is.

Diuers descriptions thereof.

The *Plexus Choroides* hath his situation in the forward ventricles [tab. 13. fig. 13.] betwixt them and the Arch, they are called *χορδοειδὴ ἀνὰ πλάτη*, because they are like the *χαρπὴν* that is, the After-birth or membrane which compasseth the Infant. But by all Anatomists they are called *Plexus Chors-formes* or *Reticulares*.

They are complications of small vessels in the ventricles of the braine compassed with the *pia mater* [tab. 9. fig. 4. OO. tab. 10. fig. 5. OO. fig. 6. MN.]

How and of what vessels they are made is diuersly set downe by the Authours of Anatomy, and because it is a speciall matter and of subtile conuayance, I will not spare my labour to set downe the diuers delineations of *Archangelus*, *Laurentius Vesalius*, *Fallopins*, and *Banbinc*.

Archangelus

Table II. Figure 7. sheweth the Braine, wherein that part is taken away which made the upper ventricles and did ly upon the Cerebellum: here also the vessell led along from the fourth Sinus, is separated from the Plexus Choroides and so elevated, that the Sinus of the Dura Meninx, and the After-braine it selfe may better be discerned.

Figure 8. sheweth the Braine yet further dissected and more of it taken away, so that the Testicles are divided that you may see the passage of the third ventricle into the fourth, and the Cerebellum uncovered from the thicke membrane.

B, The Bason or Tunnell called *Peluis* or *Indisfundibulum*. C D E F, The foure holes thorough which the phlegmaticke excrement issueth.

a Pine-apple, broade and round in the Basis, and growne smaller but keeping round to the top; and hereupon it is that it is called *κωνάριον*, and *Glandula Pinealis*: some haue resembled it to the end of the Virile member, & therefore call it *penis Cerebri*, the yarde of the braine. Somewhat long it is, and the Basis sayth *Vesalius* resteth vpon the substance of the braine, but the top regardeth vpward.

The substance of it is somewhat hard, rather sayeth *Vesalius* inclining vnto the nature of a glandule then of the Braine, and couered with the thinne membrane. The coulour of it somewhat differeth from that of the marrow, as being a little yellowish. It lyeth vnder the

Vse.

vessell sayth *Baehne* [tab. 10. fig. 6. H] which goeth to the third ventricle, from which vessell all the webs almost which are in the ventricles doe proceede: and hath the same vse that other glandules haue, which are placed vnder vessels, that is, to confirme their diuisions. For as soone as this vessell entred into the third ventricle, it is presently diuided into many branches couered ouer with the *Pia mater*; and therefore the glandule becommeth to them a strength and stay; but *Archangelus* denyeth this vse of it. Againe, it hath another vse acknowledged by *Vesalius*, *Platerus* and *Laurentius*, and that is to keep the passage of the third ventricle open that it be not stopped by the ingate of the forenamed vessell, and so the Animall spirit hindered from descending into the fourth ventricle.

Archangelus
his conceit.

Disproued.

Archangelus obseruing that this glandule was placed at the beginning of the middle or third ventricle, out of which the spirit is transmitted into the ventricle of the after-braine, thought that this glandule had the same vse that the *Pylorus* of the stomacke hath, to bee a Porter as *Galen* saith to moderate the outgate of the spirits. But the trueth is, that this glandule can haue no such vse because it is no particle of the Braine, neither adhereth to the inward sides of the ventricle, but only lyeth vpon it on the outside; neither indeed doth it so neerely touch the passage as that it can stop the same. Indeepe if it were a part of the braine (sayeth *Galen*) then it were more likely, that as the braine is dilated and compressed, the Glandule also should alter his position and sometimes open the passage sometimes shut it, but seeing of it selfe it cannot moue being no part of the Braine, this vse cannot be attributed vnto it.

The Testicles
and Buttocks.

Vnto the backside of the Pine-glandule on either hand the third ventricle and vnder the Arch doe leane foure [tab. 11. fig. 7, M N, fig. 8. N O P Q, tab. 12. fig. 10. E D F G] small bodies, which *Galen* in his eight Booke of the *Vse of parts* and the 14. Chapter, calleth thinne and long eminencies of the braine, for they swell vp round and are somewhat hard. They are particles of the braine and of the same substance therewith, but their colour approacheth nearer saith *Vesalius* to the colour of the Braine there where it lyeth next to the *Pia meninx*. In their lower part they grow out of the Braine, but aboue and at the sides they are not continued to any part of it or in it, but are onely couered with the *Pia mater*; but because they are scituate between the forepart of the After-braine and backside of the third ventricle, they are better discerned when the *Cerebellum* is taken away.

And because they carry the representation of two buttocks ioyned together, *Galen* in his 8. Booke of the *Vse of Parts* and 14. Chapter calleth them *γαστρίαι* that is, small buttocks; and if you marke well the meeting of these two, and also cast your eye vpon the spinall marrow that descendeth by them, you will readily compare them to a mans thighes set close together. Others comparing them to Testicles, had rather call them *διδυμα* then *γαστρίαι*. Others, because the bodies are not separated into parts, but distinguished onely by an ouerthwart line [tab. 12. fig. 10. betwixt E D and F G] do call those parts of them which are next to the Pine-Glandule [tab. 12. fig. 10 N] and vppermost, Testicles, and those that are lower, Buttocks: because in their lower and backward part [tab. 12. fig. 10, vnder F and G] when the After-braine is remooued, the passage out of the third ventricle into the fourth conspicuously appeareth [tab. 11. fig. 8, K, tab. 12. fig. 10. aboue K] which passage resembleth the very fundament betweene the buttocks.

Their vses.

The vse of these bodies is to sustaine the waight or bulke of the braine, least the third ventricle or the passage [tab. 11. fig. 7, 8, K, tab. 12. figure 10, I K] which goeth out of the third into the fourth should be compressed, and so the Animall spirit intercepted. Some thinke that these particles driue forward the Pine-glandule to shutte vp the passage of the ventricle: and *Archangelus* thus. The Testicles thrust forward the Glandule, and the Buttocks thrust forward the Testicles: for if you deuide these particles and enter a Probe at the back hole of the third ventricle, you shall more plainly perceiue the other part of the third ventricle scituate vnder the Testicles [tab. 12. fig. 10, I, and K, shew the whole third ventricle] which endeth into the fourth.

The fourth
ventricle.

The left ventricle which *Galen* in his 8. Booke of the *Vse of Parts* and the 12. Chapter, calleth the ventricle of the *Cerebellum*: *Laurentius* *sinus quartus*, the Common Anatomists the fourth ventricle [tab. 12. fig. 9, I, fig. 10. L M N O, with tab. 15. fig. 21. H] is scituate betwixt the After braine and the spinall marrow, for it is common to them both: so sayth *Vesalius* It is compounded of the hollownes of the *Cerebellum* and the Marrow of the backe, no otherwise then if you ioine both your hands together and make one hollownes betweene them, or as *Fallopins* hath it in his Institutions: It is scituate in the back part of the Braine,

be-

between it and the *Cerebellum* where the beginning of the *Spinall Marrow* ariseth out of the braine, for in it it is for the most part formed. It is the least and the finest of all the *Ventricles*: the figure of it is round but whitish somewhat long after the fashion of an *EGGE*. At the first it beginneth somewhat large and by degrees is straightned till at length it end in a sharp corner. For the lower and chiefe cavity of this ventricle is in the *Spinall Marrow* [Tab. 10, fig. 10, from K to O] having a hollownesse like a slit, which *Sinus Herophylus* likened to the cavity of a writing pen, the end of it which is resembled to the neb of the pen arising on either side [Tab. 12, fig. 10, N] like a wing. The vpper part of it is made of the *After-braine* and the *pia mater* encompassing it. [Tab. 15, figure 2 I H] For this Ventricle is joined with the *pia mater*, before [table 11, fig. 7, XX, neere to M N] where it ioyneth the *Cerebellum* to the Braine and to his buttocks, behind [tab. 11, fig. 8, as it were ioyning E to H] where it ioyneth the *Cerebellum* to the *Spinall Marrow*.

This Ventricle is not double but single, because out of it the *Spinall Marrow* was to be produced as *Galen* saith; now the *Spinall Marrow* is single, for it had not beene possible, or if possible, it had not beene fit that one Creature should haue had a double *Spine*. The magnitude thereof is conuenient to receyue the *Animall spirits* out of the forward *Ventricles* by the common passage or third ventricle, and to communicate them to the *Nerves* which vnder the head are distributed into the whole body, whence it was that *Herophylus* called this ventricle *Principalisimum*, the most principall. Yet it is lesse then the forward *Ventricles*, because (saith *Galen*) it conteyneth a thing of more power and Faculty. In this ventricle *Vesalius* thought was the seate of the *Memory*, but we know and are able to demonstrate that no cavity of the body is the seate either of the sensatiue soule or of any of her Faculties, but rather the solid substance of the parts.

This Ventricle we finde in Dissections (as also all the rest) to conteyne in it a watery moisture. The two forward beside this water conteyne also the *Plexus Choroides* [Tab. 4, fig. 4, O O, tab. 10, fig. 5, O O, fig. 6, M N] and the third the venal vessel [tab. 10, fig. 6, H I, tab. 11, fig. 7, V, brought out of T] which is propagated from the fourth *Sinus* of the *dura meninx*, and maketh the *plexus* as we saide before more complicated. Many there are who thinke that all these foure *Ventricles* do containe the *Animall spirits* laboured and perfected in the *plexus Choroides*.

CHAP. XIII.

Of the Tunnell, the Flegmaticke Glandule, the wonderfull Net, and the vse of the Braine.

AT the first or forward hole of the third ventricle, or at the sides of that hole or orifice [Tab. 11, fig. 7, and 8, I] we meete with a deepe cavity ioyned aboue to the Braine and made (as saith *Galen* in his ninth Book of the *Use of parts* and the third Chap.) of the *pia mater* compassing the *Basis* of the Braine. For of this *Pia Mater* lengthned out is made a round proceffe or production, [tab. 15, fig. 20, C C] whose beginning is large and ample, [tab. 12, fig. 11, E, fig. 12, B] but after is straightned into a pipe till it end in a long *Fistule* or quill (woven with small but many veines) which through a proper hole [tab. 12, fig. 11, F] made for it in the *Dura mater* descendeth and determineth into the *Pine-Glandule*. This passage by *Galen* in his ninth Book of the *Use of parts*, and of Anatomicall Administrations and the third Chapter, as also by many that haue followed him, is called *peluis the Bason*. He calleth it also in the place before named *χώραν Infundibulum* the Tunnell, because in the top it serueth as a Tunnels top to admit the Humor, and in the bottome like the pipe to let it out; for by this the thicker excrements of the Braine stored vp in the ventricles are received and transmitted to the Flegmaticke Glandule of which we shall speake by and by. *Vesalius* maketh the vpper part to be called *μυστὴρ*, and compareth it to a Bathing tub such as they vse in Hot houses. The neather part *χώραν*, which cannot be better compared then to the pipe of a Tunnell such as they tun Beere with.

Concerning the vse all Anatomists no agree; but *Laurentius* me-thinks for the fashion and the vse compareth it best to such a bagge as we cal *Manica Hippocratis*, in English commonly an *Hippocras bagge*, because through it they tun *Hippocras* which is called *Hippocrates wine*. Next to the *Bason* followeth the flegmaticke Glandule, *Galen* in his 9. Booke de vsu

Laurentius.

Glandulapart- *partium* and the third Chapter calleth it simply *adur*, that is, a Glandule. The seate of it is
under and without the Meninges at the end of the Tunnell in the saddle of the wedgebone.
For this saddle or bosome of the bone was purposely made to receive this Glandule: and
therefore the forme of them both differeth little; for it is flat, hollow above, gibbous below
and almost foure square. The substance is Glandulous, but yet more compact and harder
than other glandules. Thicke it is and compassed about with the *Pia mater* haply with that
part thereof which maketh the Tunnell, and by this Membrane it is tyed to the bone and
leaneth to two branches of the *soporary* Arteries called *Carotides*, which creepe vp by the
sides thereof. [*tab. 12. fig. 12. C D E F*] This Glandule receiue the excrements in manner
of a sponge as they fall from the braine, which excrements it not onely emptieth into the
palate, but also some fall downe by his sides through those holes which are bored in the
Basis of the Scull. Neyther was *Hippoc.* ignorant heereof, who in his Books *de Glandulis* and
de locis in homine saith, that *Humors fall out of the head through the eares, the eyes, the nose, others*
by the Palate into the throat and the gullet, some also through the veins, into the spinal marrow and
into the bloud: that is 7. wayes. For at the sides of this Glandule there are bored two holes in
the bone which descend; one forward ending in that hole where through the 2. payre of
finewes is led, the other descendeth more backward and passeth by the sharp Cleft at the
sides of that hole through which that noble branch of the *soporary* Artery ascendeth into the
Scull, of which outlets we shall speake more at large in the History of the bones.

And these are the wayes by which the phlegme is euacuated out of the braine. For the
braine being great and large stood in need of much aliment, and because it is very moist and
not very hot, out of that much aliment many excrements do arise and are gathered therein;
which excrements being of two kinds thinne and thicke, the thin do vapour out through the
Sutures, the thicke are euacuated partly by the Nostrils as we haue saide already, partly by
the Palate. For those that arise about the Ventricles and are stabled in the diuision of the
braine are purged by the forward hole & the Nose, and is called *Mucus*, we giue it a home-
ly name but proper to it, and call it Snout.

But those that are gathered in the ventricles do most what descend to the Tunnel and are
auoided by the Palate, eyther by simple spitting which we call Rheume, or else by excre-
ation or hawking which we call phlegme. And thus much of the Glandule and vse thereof.

The *Rete mirabile* or wonderfull Net which *Galen* (in the 9. Booke of the *Vse of parts* and
the third Chapter) calleth, *συντροφικὴ ἀλκυα*, [*tab. 13. fig. 14*] that is, the Net like complica-
tion, hath his name from the artificiall figure; for it is made of the *soporary* arteries, [*tab.*
13. fig. 14. AB] which arising vpward from the heart through the chest climbe vnto the head
and at the Basis of the braine neere the originall of the opticke Nerues, do make this web or
Net. This net compasseth the glandule [*tab. 13. fig. 14. E*] at the sides of the saddle of the
wedge-bone, and is not like a simple Net, but as if you should lay many fishers Nets one a-
boue another; wherein this is admirable, that the replications of one are tyed to the repli-
cations of another so that you cannot separate the Nets asunder, but they are all of them so
wrought into one another as if it were a body of net meshed together not into breadth onely
but even into thickenesse also. In these according to *Galen*, the Animall spirits make long
stay; which haue for their proper and immediate matter the vitall spirits raised vp in the
arteries and heere wrought into Animall from whence they are conueyed into the ventri-
cles of the braine. For saith *Galen* (in his 9. Booke of the *Vse of parts* and the fourth Chap.)
where Nature intendeth exactly to forme any thing shee provideth that it shall remaine
some good space in the instruments of concoction. Some are of opinion that the vitall spi-
rits are prepared in these small arteries, and some (*Archangelus* for instance) that the Ani-
mall spirits are inchoated heere and perfected in the *Plexus Choroides*, that hauing recei-
ued their power and efficacy from the Braine and the marrow thereof, they might yssue
into the ventricles and there be stored vp for vse.

Vesalins affirmeth that this wonderfull Net is onely found in the heads of beasts, but wee,
saith *Bauhine*, haue beene able to make demonstration of it in all the mens heads wee haue
hitherto cut vp, although we confesse that in Calues and Oxen it is much greater and more
conspicuous. Now these three particles, the Tunnell, the Glandule and the Net cannot bee
demonstrated before the substance of the After-braine be taken away; and the 2. latter not
before the *dura meninx* be dissected. Finally, before you make demonstration of these three
you must shew the spectators the Mamillary processes and the payres or coniugations of
the finewes, which otherwise in the search for these will be defaced.

Table

Table 13. Figure 13. exhibiteth the vessels of the Braine and their distribution, especially through the right side, whither they proceede from the internall Iugular veine, or from the sleepey Arterie, or from the Sinus of the Dura Meninx.

Figure 14. sheweth the wonderfull Net as Galen describeth it.

Figure 15. sheweth the pituitary Glandule with the Bason and the sleepey Arteries.

Figure 16. sheweth the Rete-mirabile or wonderfull Net, together with the glandule as it is found in the heads of Calves and Oxen.

TABVLA. XIII.

- A, The internall Iugular veine.
- B, The sleepey or Iugular artery.
- C, The first veine.
- D, The 2. veine which is led vnto the Sinus.
- E, The 3. creeping through the dura meninx.
- F, The fourth running into the Sinus.
- G H, The 5. and 6. going to the dura meninx.
- I, The first Arterie.
- J, A branch of the same Arterie running through the Muscles of the necke.
- K, the second artery reaching into the sinus.
- L, The third without a companion.
- M, A small branch of the third Arterie.
- M N, The 1. and 2. Sinus of the dura meninx.
- O, The congresse or meeting of both those Sinus.
- P P, The 3 Sinus of the Dura meninx.
- Q, The end thereof.
- R, The fourth Sinus of the dura meninx.
- S S, Branches of the first Sinus deriued into the Membranes neere at hand.
- T T T T, Branches of the third Sinus disperfed into the Pia meninx.
- V V, The lower small branches of the 3 Sinus.
- X X, The vpper, distributed through the Dura meninx.
- T Y, Certain surcles of the 4 Sinus sent vpward.
- aa, Others sent downward.
- b, The vpper passage of the fourth Sinus running by the Syll.
- cc, Surcles running vpward from this passage.
- de, The right and left vpper branches of the fourth Sinus.
- f, The lower branch going to the pia mater.
- g, A branch of the same passage going forward.
- h, The same bending backward to the Choroides reflected to the Cerebellum.
- i, A notable vessell into the which the 4 Sinus doth determine.
- K, The vppen. The by-partition of this vessell in the braine.
- lm, two branches of this by-partition.
- n, A surcle reaching to the organe of hearing.
- ooo, The distribution of the third veine and artery.
- ppp, Surcles proceeding from the Branches marked with o, deriued into the Pia mater.
- q, The diuision of the third artery where it entreteth into the skull.
- r, A branch reaching to the hollownes of the nostrils.
- s, The end of this in the extremitie of the vessell.
- uu, 2. Branches entring into the skull.
- x, A branch deriued vnto the eye from the coition or meeting of the branches uu.
- y, A branch attaining to the Pia mater.
- z, A branch attaining to the right ventricle.
- z, The complication of vessells called Plexus Choroides formed on either side of the branch marked with A.
- Figure 14. A B, Arteries climbing vp to the glandule or kernell of the gaine.
- Figure 15. A, The Glandule receiuing the bason.
- B, The bason it selfe, or if you will, the Tunnell called Pelus or infundibulum.
- C C, The sleepey Arteries.
- D, A branch of the artery going to the side of the Dura meninx.
- E, Another branch of the same artery going to the nostrils.
- F F, An artery in one side diuided into 2. branches, but in the other side meeting together againe.
- G, A partition of the artery creeping through the dura meninx.
- H, Another branch which getteth out of the skull and reacheth to the eyes.
- Figure 16. A, The pituitary Glandule.
- B C, The sleepey arteries going into the skull.
- D D, The wonderfull Net.

For the use of the Braine. Aristotle (in his second Booke de partibus Animalium and the 7. Chapter) writeth, that the braine was made as a common good for the behoofe of the whole Creature, to temper the feruour and heate of the heart; which opinion because it is

The use of the Braine.

sufficiently refuted by *Galen* in his 8. Book of the *Use of parts* and the second chapter, we will not insist long vpon it, onely these two things we open. First, that the heart is sufficiently refrigerated by our perpetuall inspiration and expiration. Secondly, that if Nature had intended the braine to coole the heart, she would not haue set them so farre distant, but placed it eyther about the heart or at least in the Chest: as well therefore might he haue saide that the Heele was made for the vse of the heart as the Braine.

Diuersē,

Galen.

Wherefore we determine the vse of the braine to be, first for a habitation for the soule whereby she performeth her Animall functions, as well those that are principall as also those of sense and motion. Secondly, that in the substance thereof the Animall spirits might be laboured, herein conveyed and from thence deriued into the body. For so saith *Galen* (in his 8. Book of the *Use of Parts* and the 13. Chapter, and the 9. Book and the 4. Chapter.) *In the whole substance of the body of the Braine is the Animall spirit wrought and reserved, not only in the ventricles*: and in his 12. Booke of Method the 5. Chap. and the third *de locis affectis* and the 7. speaking of the falling sicknesse he saith, *It is caused in the braine, the humor hindering the Animall spirits which are contained in the ventricles that they cannot issue out*. Thirdly, that the Nerues and spinall marrow might proceede from the marrow thereof, which is so manifest as we neede not cite the places of *Galen* to proue it. For the Nerues receiue from the braine as from a principle, as we say *à quo* and of dispensation, the Animall vertue and sensatiue soule which do reside in his substance and do distribute the faculties of sense and motion into the Organs or Instruments of sense and motion as it were through Channels hauing in them the Animall spirits to convey the same faculties.

The Animall spirits.

Aristoteles Comparisons.

This Animall spirit although it performe many seruices, is one and the same; leading all the faculties of the sensatiue soule through the Nerues into all the parts of the body: but the Instruments into which out of the braine it is powred into the Nerues are manifolde. Wherefore if they runne into the eyes which are the Organs of the sight, they make Vision; if into the eares, Hearing, &c. This *Aristoteles* (in his second Booke *de generatione Animalium* and the last text) elegantly declareth by the example of a Smiths hammer, for as the hammer is but one instrument yet doth many seruices according to the variety of subject vpon which it worketh; so is the spirit in the worke of Natures administrations; and as the beames of the Sunne are one and the same yet appeare diuers if they light vpon diuers colours, so is it with the Animall spirits.

The seate of the sensatiue soule.

Animall motion and sense.

The substance of the Braine although it be deuoid of Animall motion and sense (for it is not deuoid of Naturall) yet is it the originall of sense and voluntary motion which we may better perceiue if we consider that disease which we call the Apoplexy. For those that are Apoplectical although all their Instruments of the senses are perfect, yet because the Animall spirits are intercepted they haue no sense at all. For the original of the spinall marrow being totally stopped, all the parts vnder it doe loose both sense and motion: so also if the Nerue which is conveyed to any part be obstructed, that part is deprived of sense and motion. Hence it followeth that the braine is the seate and residence of the sensatiue soule and the fountaine of sense and motion. Of sense, because it receiue the impressions of all sensible things. Of motion because it dispenseth the knowledge of auoiding that which is hurtfull, and desire to follow after that which is profitable and behoouefull.

Naturall sense

Hippocrates.

As for Naturall sense and motion there is a great question whether the braine haue them or no; and first for sense. *Hippocrates* (in his Booke *de vulneribus capitis*) saith, that the braine hath present and exquisite sense about the *Sinciput* or sides of the head, because in this place the bone is the thinnest and most of the braine is there contained; beside, the skinn of the head is the thinnest also. Moreouer saith he, the diseases of the braine are the most acute and dangerous, yea for the most part mortall and hard to bee iudged of by those that are not very well experienced.

Galen.

Galen (in his first booke of the cause of *Symptoms* and the 8. Chap.) saith, that the braine was not made by Nature an instrument with sense, but so that it is able to comprehend or perceiue all those things by which it suffereth, as if he should haue saide, The braine is not made to be a particular instrument of sense, so as it can perceiue or apprehend colours onely as the eyes, fauours onely as the tongue, &c. but it is a common instrument of sensation discerning colours, fauours, smells, sounds and tactile qualities; and in a word all sensible objects.

Wherefore the braine feeleth vniuersally whatsoever is offered vnto it, not with choise as the eye which receiue the sound but onely his owne object and so in the rest. It remaineth therefore that the Naturall sense of the braine is none at all or at least so weak and

and dull as it is hardly perceiued, for in his substance there is rather a faculty of Touching then an instrument of Touch.

Fernelius thinketh that all motion is from the marrow of the braine, and all sence from his membranes; because the body of the braine is perpetually mooued but hath no feeling at all: on the other side, his membranes are of themselves immoueable especially the *Dura mater*, but feelee very exactly. So in the Lethargy or Phrensie which are diseases of the substance of the braine there is no paine at all, but if a sharp vapor or humor be raised vp vnto the Meninges, then grievous paine followeth. Moreouer the spinall marrow and all the nerues haue their marrow from the braine and that couered with the Meninges, all which haue the same and no other power or faculty then what they receiued from their originall: wherefore the forepart of the braine is the beginning of Sence, the hinder part of Motion, but of Touching the Meninges or Membranes are the originall. Those nerues which are full of marrow are the instruments of Motion; of Touching, those whose greater parts are produced by the Meninges. And this is *Fernelius* his Philosophy concerning this poynt, but how consonant to reason we shall see afterward.

Concerning the motion of the braine great difference there is among Authors. *Galen* in his 8. Booke of the *Vse of parts* and the second Chapter, sayth it hath perpetuall motion. *Vesalius* denies it, answers his arguments and addeth that he could neuer perceiue any such motion either in great woundes of the head, or which is more in his dissections of liuing Creatures. *Fallopins* halteth in this poynt, he sayes it but he dares not auouch it.

Platerus thinks that those that say it moues, mistake the motion of the braine for the motion of the third *Sinus*, which beateh like an artery. *Columbus*, *Archangelus* and *Laurentius*, doe all consent that it moueth continually; and instance in woundes of the head. *Laurentius* is so confident that he sayth he is a mad man and wants his senses that will deny it. To resolve vpon somewhat among so many opinions, wee thinke; that the braine is not moued by any Animall or voluntary motion, but by a Naturall and that double: one proper of his owne, another from the arteries, albeit this last *Archangelus* doth deny, because these arteries that runne aboue are too small, but those that are in the bottome of the braine much lesse, yet it giueth the power of voluntary motion to other parts.

This motion is proper and peculiar to the braine, for the generation, nourishment and expurgation of the Animall spirit, for it is dilated and againe constringed as may be seene in woundes of the head where a notable part of the Scull is taken away, as also of the membranes sayth *Babine*. And in children new borne in the mould, the braine is so manifestly seene to beate and pant, that euen the bones which at that time are very soft are mooued therewith. When it is dilated it draweth out of the *Sinus* of the *dura mater* (some say out of the wonderfull net or web of the *sopranie* arteries) vital spirits and ayre by the nostrils, for the restauration and preservation of the Animall spirits, and when it contracteth it selfe it driueth out the Animall spirits laboured in his substance through the nerues, as through pipes and canals into the organs of sence and motion, or (as *Archangelus* hath it) out of the foreward ventricles being contracted into the third and fourth, and so into the organs aforesaide: which spirits when they arrive in the particular parts they nourish the Animall spirits bred and fixed in those parts. For the Animall spirit floweth through the nerues into all the parts, not only to be the conuayer of the sensatiue and mouing Soule, but also to giue nourishment to the Animall spirits fixed in the parts; and this spirit is the *medium* or Meane by which the Sensatiue Soule and all his faculties which are incorporeal are ioyned with the body. The outward parts because their instruments are farther off, stood in need of nerues as it were Channels through which the Animall spirits accompanied by Vitall as it were by guides might bee conuayed, but the inward parts because their instruments are neare and at hand needed no nerues, but receiue the same by blind and inuisible bywaies yet guided by the same Vitall spirits.

We haue also sayd that at the entrance into, and at the out-gate from the heart there are certaine Valves or floud-gates set, and their uses wee haue allotted. Now *Archangelus* is of opinion that the Buttocks and Pine-glandule of the Braine doe here the same offices that the valves did in the heart. For saith he, in the dilatation of the braine the way out of the third vnticle into the fourth closeth it selfe, and beside is shut vp by the glandule falling betweene the Buttocks, that no part of the spirits can returne out of the fourth ventricle into the third. On the contrary, in the contraction the glandule is lifted vp and the Buttocks are diuided, and so a way is made for the Animall spirit to flow out of the third ventricle into the fourth.

Fernelius has Philosophy about this.

The motion of the Braine: *Vesalius* against *Galen*.

Laurentius. What we resolve of.

The use of the motion. How the motion is discerned:

The Animall spirits.

A witty conceit of *Archangelus*.

Con-

Divers opinions of the generation of the Animal Spirits.

Galen.

Concerning the generation of Animall spirits there are diuers opinions; especially seauen, one of *Galen*, another of *Vesalius*, a third of *Columbus*, a fourth of *Argenterius*, a fifth of *Archangelus*, a sixth of *Laurentius*, and a seauenth of *Varolius*, to which *Banvine* our author subscribeth.

Vesalius.

Galen's opinion was, that they were made of the vitall spirit brought by the *soporarie* arteries and of ayre breathed in, mary as for the place of their generation he seemeth to be altogether vncertaine; for sometimes he assigneth the *Plexus Choroides*, sometimes the ventricles, sometimes the substance and body of the braine.

Columbus.

Vesalius sayeth they are laboured in the right and left ventricle by a power and efficacy receiued from the braine, and haue for their matter vitall spirits from the heart, and ayre drawne in by inspiration ascending through the third ventricle.

Argenterius.

Columbus sayth they are made of ayre drawne by the nosethrills and altered in the cauities of the forehead bone and the wedge-bone, and carried through the pores of the spongie bone to the forward ventricles where it meeteth with the vitall spirit sent vpward from the heart by the *soporarie* arteries, and powred into the *Plexus choroides* which is in the ventricles; both which spirits and ayre, sayth he, by the perpetuall motion of the braine and this *Plexus Choroides* are exactly mingled, and of them the Animall spirits are generated in that *Plexus Choroides* which is the ventricles, and this he sayth was his owne inuention.

Archangelus.

Argenterius will haue but one influent or moouable spirit besides the fixed spirits of the particular parts, whose arguments shall bee sufficiently answered in our Controuerfies by *Laurentius*.

Laurentius.

Archangelus opinion is, that the Animall spirits are made of the vitall, changed by many exagitations and alterations by the arteries which make the *Rete mirabile* and the *Plexus Choroides*, but receiuing their vttermost perfection in and by the substance of the Braine, and so become a conuenient vehicle of the sensatiue soule. The proceffe of which generation he sayth is after this manner. There is an inchoation or beginning made in the *Rete mirabile*, but the plenarie perfection is in the *Plexus Choroides*, yet that from a power or facultie of the marrow of the braine in which alone such power resideth; being so perfected they are powred out into the ventricles (which adde nothing to their generation) as into store-houses or places of receite where they are kept to bee transported into the whole body.

Varolius.
What we resolve of.

Laurentius thus, the Animall spirit is generated of the vitall spirit and the ayre breathed in; whose preparation is in the labyrinthian webs of the small arteries, and in the vpper or forward ventricles; but they receiue a farther elaboration in the third ventricle and their perfection in the fourth, and from thence by the nerues are diffused into the whole body, but he reprehendeth those that auouch that this spirit receiueh his forme and specifical difference in the webs before named.

Banvine.

Finally *Varolius* and with him *Banvine* and wee with them will resolve, first for their matter that it is arteriall blood abundantly fulfilled with vitall spirits and ayre drawne in by the nosethrills; for the manner we say it is thus. The spirituous and thin blood is sent vp from the heart by the *soporarie* arteries vnto the braine, and is powred out into the *Sinus* of the *dura mater* whilest they are dilated as is venall blood out of the veines. With this is mingled ayre drawne by inspiration through the nosethrilles, and arriuing into the braine through the pores of the spongie bone. These substances thus mingled and mixed in the vessels, whilest they are carried through the conuolutions of the Braine are altered and prepared, purged also from phlegmatick excrement, which whilst it nourisheth the braine, the more subtile part is transfused into his substance, and there, that is, in the marrowy substance of the braine, it is laboured into a most subtile Animall spirit, and so is from thence by the same passages returned and communicated to the spinal marrow and to the nerues of the whole body. Neither saith *Varolius* is it necessary that these spirits should haue any cauities to bee laboured in; and hee sheweth it by an example. When wee shut one eye the Animall spirit in a moment returneth vnto the other, so that it dilateth the ball or pupill of the other, and yet is there no manifest passage betweene them, sauing those insensible pores which are in euery nerue and also in the substance of the braine. And hereunto subscribeth also *Platerus* on this manner: The common opinion saith he, is that the Animall spirit is generated and containd in the *Plexus Choroides*, which I cannot approue as well because the vesselles are so very small, as also because so many excrements of the braine fall through the ventricles. I thinke therefore that the Animall spirit is tyed to the substance of

Platerus.

of the braine, so that the braine is neuer without Animall spirits, neither can the Animall spirits subsist in any part without the substance of the braine: for what else is the inward substance of euery Nerue but a kinde of production of the braine compassed about with a production also of membranes of the same?

And thus much shall bee sufficient to haue sayed concerning the vse of the Braine and the generation of the Animall spirit. Now wee proceede to the After-braine or the *Cerebellum*.

CHAP. XIII.

Of the Cerebellum or After-braine.

Hat the whole Masse of the Braine is diuided into the Brain and After-braine we haue already shewed. The cause of this diuision *Varolius* taketh to be this. Where- as of those things which are apprehended by the senses there are two chiefe, differing much the one from the other, yet both of them so immediately seruiceable to the vnderstanding that they cannot bee substituted one for the other; whereof one belongeth to the Sight the other to the Hearing; and because there is required to the perfection of sight the mediation of a moyst and waterish body as we see in the eyes; therefore for their behoofe especially and of the visible Species which they admit, that part of the braine was made which is the softer and so great that it filleth almost the whole Scull; and this is called properly *Cerebrum* or the Braine. But because those Species which are apprehended by sound, or resounding, do require a kinde of driness in their Organ, as *Hippocrates* excellently acknowledgeth (for where there is onely moysture there is little or no resonance at all): therefore vnder the braine in the backpart of the head there is ordained and scituated a lesser and faster portion which they call *Cerebellum* we the After-braine, which as it is truly harder then the braine it selfe, so is it consequently dryer. And this is *Galens* opinion in the 6. Chapter of his 8. Booke *de usu partium* where he saith; that therefore it is harder then the braine because it produceth hard Nerues; albeit *Vesalius*, *Columbus* and *Archangelus* wil not admit any difference in their substances. Wherefore the Braine it selfe was especially made for the behoofe of the eyes, and their objects: the After-braine for the vse of resounding species or such things as were to be represented to the hearing. And because the sight is more excellent then the hearing, ministring vnto vs more difference of things, therefore it is seated aboue the After-braine.

The *Cerebellum* or After-braine, called in Greeke *παρυκισμα* and by *Aristotle* *εμπρις*, that is *after the Braine*; is as it were a priuate and small Braine scituated in the backe and lower part of the scull vnder the Braine [tab. 11. fig. 8. R R] from which it is separated: it is also couered with both the Meninges or Membranes, and is vnited to the spinall marrow for a little space where also it affoordeth a part out of it selfe to make the bulke of the same narrow.

In brute Beasts it is round and acuminated or growing sharpe and taketh vp almost all the backpart of the head. It is continued on eyther hand to the sides of the Braine by two orbicular or round portions: [tab. 11. fig. 8. neare H G] But to the spinall marrow it is ioyned in the very middest, yet toward the backside, [tab. 12. fig. 9. E] by the interposition of the *Pia mater*: And because the fourth ventricle should not there start open it is compassed with the thinne Membrane which is spred as farre as to the Buttocks. [tab. 11. fig. 8. betwixt O P and Q] It is separated from the braine that through the thicke Membrane the vessels might be securely conueyed into the depth of the braine.

The forme of it is broader then long or deepe, and in the lower and backpart it resembleth a flat bowle, in the middest whereof there is a sharpe impressiō ietting out from the bunch of the Nowle-bone; forward toward the buttocks of the braine it runs into a sharpe wedge hauing that figure because the place will admit no other.

It consisteth of three parts, the right, the left, and the middle (which yet are not diuided but continued) because of the bunch of the Nowle-bone, of which we shall speake more particularly heereafter.

The right and the left parts are like two bowles set together, [table 12. fig. 9. B D] in the middest of which where the bowles do not touch, is placed the third part which is rounde and

and runneth as it were into a Ring from before backward, and maketh those processs which are called *vermiculares*. By reason of these parts it hath three-fold impressions, some ouerthwart and scored along thorough it; others running right downward which are ioyned on eyther side as it were vnto a Center. For the lines it hath are long and almost superficially, yet diuided manifold and distinguished by the thin membrane running betwixt them. The reason why they run in the superficies or surface onely is, because if they did descend deeper as we see in the Conuolutions of the Braine it selfe, they would perforate the *Cerebellum* even vnto the ventricle. They are also manifold that their plenty might supply their superficial course; as for those long and winding contortions which are in the braine, in this After-braine they are not to be found.

The Lines.

Why superficially.

The substance

The substance of it is almost the same with the substance of the Braine it selfe, if wee take it freed from the *Pia mater*, excepting in the *Basis* of the Braine where the spinall marrow beginneth, which is harder then all the other parts, yea then the After-braine it selfe.

G G, In this place the After-braine did grow to the spinall marrow. H, The cavity in the spinall marrow maketh the fourth ventricle. I K, The anterior and posterior proceffes of the braine, called *vermi-formes* or the wormy proceffes.

For this spinall marrow neither in colour nor in hardnesse is answerable to the *Cerebellum*, because the After-braine is yellower or rather more Ash-coloured, being no where white but in the surface of his ventricle; but the spinall marrow is exceeding white, as also is the Basis of the Braine which giueth beginning vnto it.

The quantity of the After-braine is much lesse then that of the Braine. The Braine being as sayth *Fallopins* foure times, as *Vesalins* would haue it, tenne times as bigge as the *Cerebellum*.

In the middest thereof it hath a broad *Sinus* or hollownesse not very deepe, which maketh as it were the rooffe or vpper side of the fourth ventricle, for the rest of it is covered with the thin membrane; [tab. 15. fig. 21, H] with-in-ward it hath no cauities as hath the braine, because it neither aboundeth with so many excrements, and those it doth gather, it easily turneth downe on the out side.

It hath two proceffes (*Platerus* reckons foure) [table 15. figure 21. C D] which because they are like to wormes in rotten wood, *Galen* in the 14. Chapter of his 8. Booke *de vsu partium* calleth *vermi-formes excrefcencias*, Wormy proceffes, one of which regardeth the fore side, the other the back of that ventricle which is common to the After-braine and the

spi-

spinall marrow. These processes are diuersly orbiculated or rowled vp, consisting of many particles, not oblique or right but transuerse, coupled together by the *Pia Mater* or thin membrane, whose end or top is embowed and thinne (which *Aurantius* calleth the *pease*) and entreth the cavity which they call the Cisterne, yea into the fourth ventricle.

Aurantius

Archangelus
his opinion of
the substance
of the wormy
processes.

Archangelus maketh this wormy processe not as *Galen* would haue it, to bee of the substance of the braine and a part thereof, but a long membranous body, being indeede nothing else but the *Pia Mater* corrugated or foulded together, which in the dilatation of the braine is necessarily extended: but in the contraction is corrugated or crumpled vp like a worme.

For because (sayeth hee) the braines of those that die are contracted and fall into themselves, it necessarily followes that after death the membrane must in that part bee contracted.

It appeareth also thicker then otherwise the crumpled membrane would, because being scituated in a low part, it receiue the moysture there collected and encreaseth with that additament. Wherefore sayeth hee the worme as it is a worme is of no vse at all. But to returne.

The first pro-
cesse.
Galen vse of
the wormy
processes.

We saide these wormy processes were two, the first which lyeth on the forepart [*tab. 15. fig. 12. C*] neare the buttocks is thought by *Galen* in the 5. Chapter of his 9. Booke of Anatomical Administrations, to keepe open the passage of the third ventricle into the fourth; albeit *Vesalius* taxeth *Galen* for assigning that vse vnto it. *Galen* also in the 14. Chapter of his 8. Booke *de usu partium* sayth further, that this processe when it is extended ouer the foresaide passage doth wholly obstruct or stop the same; but if it be reflected backward and rowled vp, his imbowed parts do draw the membrane to them adioyned, and the passage is so farre opened as way is made by that retraction. For as it is reflected and rowled round, by how much the length of it is diminished by so much the breadth is encreased; wherefore it behoued not, that these processes should be either too thicke or too thin: not too thicke, for then they could not haue exactly closed the passages because they should haue had no slender parts which might haue insinuated themselves into the narrow straits of the passages. Againe, if they had beene too thin, the passages before said could neither haue bin exactly shut nor well opened.

And least these processes should altogether fall into the passages, Nature hath on eyther side bound and conioyned them to the buttocks with slender bodies which the Anatomists call *Tendines* proceeding from the thinne membrane; which membrane being extended to the hinde-most ventricle maketh the end of this processe. And this is *Galen*'s Anatomy concerning these processes, and deserueth well to be considered of, especially if wee make our dissection of the head after the ordinary and accustomed manner.

The 2. pro-
cesse.

The other processe [*tab. 15. fig. 21. F D*] which is the hinder, and from behind inclineth forward, doth not beare out as the former did; but his poynt is rather hid in the substance of the *Sinus* of the After-braine.

Their vse.

The vse of the first is to vsher the spirits; of the second that the way or passage of the fourth ventricle (which *Galen* in the 11, 12. and 13. Chapters of his 8. Booke *de usu partium* calleth the ventricle of the *Cerebellum*) might not bee obstructed by the After-braine pressing vpon it. But wee are of opinion that this is the common vse of both the processes, because this passage (so often now mentioned out of the third into the fourth ventricle) ought neuer to be shut but to remaine alwayes open that the Animal spirit might haue perpetuall free influence into the spinall marrow. *Platerus* thinkes that this vse is common to all the foure processes (for he reckoneth foure.) But *Vesalius* assigneth to them no other motion or office then to the rest of the substance of the *Cerebellum*, but if you aske his reason, I thinke it was onely that he might gain-say *Galen*.

Vesalius sup-
posed

The Vse of the
Cerebellum.

At the sides of these processes we meete with two other portions which are continuated to the spinall marrow [*tab. 15. fig. 21. G G*.]

The vse of the After-braine (as saith *Galen* in the 6. Chapter of his 8. Booke *de usu partium*) is that from it the harder nerues might haue their originall: which notwithstanding *Vesalius* and *Columbus* doe denie. *Archangelus* and *Platerus* esteeme it to bee of the same nature with the braine and adorned with the same faculties. *Galen* thinkes that that Animal spirit being contained in the whole substance of the braine, not onely in the ventricles thereof, is in great quantity treasured vp in this After-braine, as being to be the originall of all the sinewes which were to bee distributed into the whole body: and that those middle

dle distances which tye together the parts heereof, are the paths and wayes wherein the Animal spirits disport themselves.

Finally, *Varolius* conceiue, (which we partly touched before) that the Braine was especially made for the eyes and the visible objects. The After-braine for the eares and resemblances of sounds to be conueyed vnto them.

Varolius.

CHAP. XV.

Of the spinall Marrow or pith of the Backe.

THE name of Marrow is properly attributed to that substance which is simple and vniforme, moist, fat, white, without sence, contained in the Cavity of bones, and hath his originall from the blood; which through the veines slideth by secret pores & passages into their hollownesse or spongy sides. It becommeth white and as it were spermatall by a mutation it receiveth from the bones, because in them it is stored to be their proper nourishment & to refresh them when they are heated & dried by motion or other violent causes.

What true marrow is.

But of this marrow wee do not intreat at this time: the name is improperly given to the Braine also and the pith of the Backe: For the Braine it selfe is called *μυελος ἐγκεφαλίου* *medulla cerebralis*, the Marrow of the Braine, because saith *Plato* the substance thereof is marrowye, although there be great difference betweene them, for that it will not melt and consume as marrow doth, and beside is inuested or clothed with both Membranes the thicke and the thin *meninx*.

Why the braine is called marrow. *Plato.*

Moreouer to distinguish it from ordinary marrow, it is called by *Galen* *ῥαχιδος σπινάλις*. By *Hippocrates* in his book *de Carnibus* *varia* *Dorsalis*, by others *Cervicalis* and *Lumbaris*, because it descendeth through the Neck, the Backe and the Loynes, and filleth the whole spine or Ridge-bone.

The names of the pith.

Now there is a double acceptation of the Spinall marrow, for in the larger signification it signifieth the whole marrow of the brain lengthened out, one part wherof is yet contained in the Skull, [*Tab. 17. fig. 1 from D to E*] the other continuall with the former yssueth at the great hole of the Nowle-bone & descends to the very end of the ridge. [*Tab. 16. fig. 1. from A to H*]

A double acceptation of the spinall marrow.

But in a strict & more proper acceptation it betokeneth that part of the marrow which without the Scull is contained in all the racke-bones or *vertebra* of the spine or chine. [*ta. 16. fig. 1. is an expresse Image of it*] Wherefore that it may be free from all ambiguity, the history thereof is on this manner.

That which is commonly called the Braine, that is, the whole substance included within the Scull we haue diuided into the Shell and the Kernell or Marrow. For these two differ in colour and consistence. That which on euery side compasseth the marrow is Ash-coloured; the marrow it selfe is white and of a more solid, fast and compacted substance: and these two parts in Greene or fresh heads are distinguished by many oblique lines, so that with a rayser they may be separated if a man haue a steddy and cunning hand, yet not without breaking both the substances; so that *Archangelus* said well, that the white was drowned in the Ash-coloured as the cristalline humor of the eye is in the glasse; and as the glasse humor is esteemed to be the Aliment of the cristalline, so the Ash-coloured substance may well be thought to be the foode of the white, because the Ash-coloured appeareth so to be by reason of innumerable veines disseminated through it.

The parts of the Braine.

Archangelus.
An elegant Comparison.

The marrow it selfe may be said to be double, one Globous or round, the other Long. The Globous part which is like the figure of the Scull, is of a great bulke and therein are ventricles excauated or hollowed. At this and continuall with it hangeth the other called *Cerebellum*, of which we haue intreated in the Chapter going before according to the receiued opinion of Anatomists.

The marrow double. Globous.

The Long marrow of the Braine which is like a Pith or staffe may be deuised into that part which is contained within the Scull, & that which is yssued out which properly is called the spinall marrow; although some there are that giue this name vnto all the Long marrow of the Braine as well within the Scull as without; and this is it of which wee now speake.

Long.

The Spinall Marrow therefore according to this large signification taketh his beginning (as *Galen* saith in the tenth chapter of his 8. Booke *de vsu partium*) from the backe ventricle of the Braine; for he thought it nothing else but the Braine lengthened, which may seeme to agree with the Scripture which calleth it *The silver cord*. And this, he saith in the twelfth chapter

The originall of the spinall marrow.

Ecclesiastes.

ter of the former book, is continuat onely with the Braine at the Basis thereof.

There be many opinions of the originall of this spinall marrow, we will reckon vnto you the most notable.

The 3. Mem-
branes of the
Marrow.
The first.

The vse of
the humor.

The first is that of *Hippocrates* in his booke *de Carnibus*, where he saith in generall words that it ariseth from the Braine. *Galen* more particularly and distinctly, from the hinder ventricule of the Braine. The common opinion is that it ariseth out of the *Cerebellum* or after-braine. *Vesalius* saies from the Basis or foundation of the Braine. *Archangelus* from the Globous part of the marrow of the Braine, betwixt the braine it selfe and the *Cerebellum*, for those that say it hath a double beginning say as much as nothing. *Platerus* thinketh that it proceedeth like a new Long Braine from the Basis of the other and receiueh increase of strength from the *Cerebellum* also. *Columbus* saith it is nothing else but a Long Braine hauing a double beginning, the one greater from the Braine it selfe, the other lesser from the after-braine. The beginning it hath from the braine is but single, that it hath from the after-braine is double and as it were forked into a right and a left. The greater originall is from the forepart of the braine but a little distant from the Region of the Opticke sinewes, and therefore, saith he, I am constrained to confesse that the 3, 4, 5, 6, 7, and 8. paires of sinewes do not arise from the braine but from the spinall marrow.

Varolius who indeed was excellent in dissecting of the head saith, that there yssue from the braine and the *Cerebellum* foure roots making one notable trunk which they call the spinall marrow, out of which do yssue Nerues deriued vnto all the parts of the body. *Laurentius* is also of the same opinion. The truth is, that it is a production as well of the braine it selfe as of the after-braine out of which it proceedeth as a stemme from the roote, which we shall more particularly shew afterward.

This spinall marrow lying vnder the *Cerebellum* to which it is continewd, taketh vp that hollownes of the Scull which is aboue the great perforation or hole in the bone of the Nowle or back-part of the head; and the beginning thereof for the length of foure fingers breadth cleaueth to the braine within the Scull, [Tab. 17, fig. 1, from D to E] the latitude and depth of that originall are so æquall that it appeareth almost circular neere the quantity and forme of an Hens Egge as *Archangelus* saith; and from this originall those Nerues which are accounted the proper sinewes of the braine together with the Organs of smelling are produced and deriued into the Instruments of the five senses, as *Varolius*, *Plater*, *Archangelus*, *Laurentius*, and *Dominicus* do ioyntly agree.

But the spinall marrow properly so called or the other part of it which is continuall with the former [Tab. 16, fig. 1] is wholly without the Scull. For when the marrow of the braine now lengthened attaineth vnto the great perforation in the Nowle-bone [Tab. 13, fig. 17, H] it descendeth and passeth along through the holes of the rack-bones euen to the end of the *os sacrum* or holy bone. It passeth I say through the bones themselves, least being soft and like the substance of the braine as *Galen* speaketh, it should in the length of his production suffer violence by those things which might light vpon it, whereas now the bones are as it were a safe conduct and firme defence thereunto all the way that it passeth.

And hence it is, that the *Gracians* call this perforated part of the spine, *ἡ ἁγία στήλη* *sacram fistulam* the holy pipe. Sacred or holy because it containeth a principall part, and a pipe because it is as it were fistulated or bored, through which Cavity such a substance is transported as where from all the other Nerues are produced.

It is inuested or cloathed with three membranes which *Hippoc.* in his booke *de Arte* calleth *ἐνυττα*. The first of which, according to *Galen*, ariseth from a strong ligament exactly fastening the fore parts of the *vertebra* or rackebones, which ligament in the backpart determineth into a Nervous and strong coate, least in the bending or extension of the spine it should be broken or offended by the bones, because it is contained not as the braine in any immouable bone, but in rack-bones, which are not onely moued but also sometimes somewhat dislocated. Wherefore the Nerues also which arise from the spinall marrow properly so called (least they should be offended by the hardnes of the bones through which they passe) are clothed beside the two Meninges with this third coate also.

About this is a thicke and slimy humour powred, as also about all the ioynts and parts that were to bee moued; least being ouer dried they should suffer paine, and so their actions or functions be interrupted; which wisdom of Nature men doe imitate when about the Axle-trees of Carts and Coaches they smear a soft and viscons grease that they might more euerantly moue.

The

The second membrane ariseth from the *dura mater* or hard Meninx; the third from the *pia mater* or thinne Meninx [Tab. 16. figure 1, expresseth the coates ioyned together] which two are not separated as they bee in the braine: moreover the thicker secureth the marrow from the bones, the thinner infoldeth his vessels and closely bindeth together his soft substance, for through the thinne membrane the veines and arteries which nourish the marrow and supply it with vitall spirits are conuayed; which vesselles we haue obserued to proceede from the veines and arteries of the loynes as wee haue already shewed in the third Booke.

The second
and third
Membrane.

The substance of this spinall marrow is all one with that of the Basis of the braine, or rather of the globous marrow. Wherefore it is somewhat hard, compacted and white, yet so that it is much harder then the braine it selfe. And *Galen* in diuers places of his ninth Booke *de vsu partium* saith, that this spinall marrow is the originall of the harder nerues, as the fore-part of the braine is of the softer: for to the strength of motion a harder production was more behoofefull; and for the exactnes of sense a softer. Note againe that the further it is distant from the braine, by so much it is harder & more compact; neither is it answerable to the colour & hardnes of the *Cerebellū*. For the *Cerebellū* or after-braine is only white in the surface of his ventricle, other-where it is yellowish or Ash-coloured; but the spinall marrow is very white most like to the marrow of the braine, sauing that it is without any contortions or conuolutions, because it is made onely to receiue & not further to labour that it hath receiued.

The vessels of
the marrow.

His substance.

Galen.

With the Braine it hath these things common; first his substance, secondly that it is an originall of sinewes (*Galen* addeth of all sinewes) and is compassed with both the Meninges. Yet heerein they say it doeth not communicate with it, because the braine (though it bee containd within an immouable bone) yet beareth and is moued; whereas this marrow albe it be containd within mouable spondels or rack-bones, is not it selfe at all moued. But if that motion bee in the substance of the braine by an in-bred faculty, and the spinall marrow hath the same nature and substance that the braine hath, me thinkes it should bee reasonable that this marrow should bee moued in like manner as the braine is moued, albeit our sense is not apprehensue of it. And truly *Archangelus* conceiueth that it hath a motion, and when it is dilated receiueh Animall spirits from the fourth ventricle, and when it is contracted powreth them againe forth into the nerues which arise there-from.

What it hath
common w. th
the Braine.

The figure of it is long, thicke and large at the originall, [Table 17. Figure 1. from D to E Tab. 16. Figure 2. from A to B] and though being gathered together it become somewhat narrower, yet is it not (as some thinke) by little and little continually attenuated till it come to the extremity of the *os sacrum*: for as far as the *vertebrae* of the loynes [Table 16. fig. 1. from I to K] it keepeth an equall thicknesse almost; although *Galen* and *Vesalius* did thinke that it was consumed as it sent more nerues out from it. *Fallopins* in his obseruations and *Platerus* doe not thinke that it groweth lesse at all. Yet wee must needs acknowledge that we find it fuller and thicker in the neck whence those great nerues issue which are dispersed through the armes [Table 16. fig. 1. from I to K] and in the loynes whence proceede the great nerues of the loynes which descend vnto the thighs; [Tab. 16. fig. 1. from B to C] and that afterward when it commeth nearer to the *os sacrum* his marrowy substance is somewhat abated.

The figure.

A cavity or *Sinus* there is formed in it presently after his originall whilest it yet remaineth within the Skull; which is like a writing-pen, and therefore it is called *Calamus scriptorius* [Table 12. fig. 10. KLNO] for it is hollowed into a poynt or nebe becomming lesse by degrees, because in that place there are no more excrements.

His cavity.
Calamus scriptorius.

This cavity maketh the middle part of the fourth ventricle of the braine; for the rest of the ventricle is formed by the after-braine [Table 15. figure 21. H] at which place the After-braine is ioyned to this marrow. [Table 15. figure 21. GG is ioyned to B C as also in the 12. Tab. and fig. 10.] *Archangelus* conceiueth that this cavity is vnder the fourth ventricle and continued with it, and that out of the fourth ventricle into it the Animall spirits doe flow, and that from this cavity they are distributed most what into all the five senses.

Archangelus.

And although the marrow bee but single and seemeth to haue no manifest cavity, yet in the very middest it is deuided into two parts by the thinne Meninx as far as to the rack-bones of the loynes; so that on either side there appeareth a little cavity which may not onely be demonstrated in the marrow of an Oxe if it bee lightly boyled, but also as sayeth *Platerus* in a mans, because it may bee parted asunder without laceration. *Archangelus* thinks this cavity to be sufficiently manifest to the eye; we are sure to the vnderstanding it is most apparant, by that we finde in those that are troubled with the Palsie, in whom sometimes one side sometimes another is alone affected. Howsoeuer the marrow appeareth simple and

His cavity.
Calamus scriptorius.

Table 16. Figure 1. sheweth the true forme of the spinall Marrow properly so called, together with his membranes and nerves proceeding from the same.

Figure 2. sheweth the spinal marrow naked and bare, as it appeareth both within the Skull and without, together with his nerves as most part of the Anatomistes heretofore haue described it.

A, The beginning of the spinall marrow where it falls out of the skull.

B, the thicknes thereof in the spondels or rack-bones of the loynes.

C, the diuision thereof into strings, or hairy threds.

D, the seauen nerves of the necke.

From D to E or from 7, to 19, shewe the nerves of the backe.

From E to F, the nerves of the loynes,

From F to G, the nerves of the os sacrum or holy bone.

H, the end of the marrow.

IKL, do shew how the nerves do issue from the marrow in strings.

MM, the knots of the sinewes made of the coniunction of those strings.

NO, the membranes that inuest the marrow.

Figure 2.

A, the beginning of the spinall marrow in the Skull.

4, 5, 6, 7. These Characters shew (according to Vesalins opinion) how the coniugations of the nerves of the braine doe take their originall from the marrow remaining yet within the Skull.

B, the egresse of the spinall marrow out of the skull.

C, the cords or strings whereinto it is diuided.

D 7, the marrow of the neck and seuen paire of sinewes.

E 19 twelve pairs or coniugations of nerves proceeding from the marrow of the Chest.

F 24, the marrow of the loynes and 5. paire of sinewes.

G 30, the marrow of the holy-bone and 6, paire of sinewes.

H, the extremity or end of the spinall marrow.

undeuided passeth through the whole necke and the Chest euen vnto the loynes and lower; [Table 16, Fig. 1. from A to B] and in his passage it scattereth nerves out of his sides: afterward, that is, at the rest of the loynes it is no more simple but deuided into many small threds and filaments, very much resembling a horse tayle and so runneth on to the end of the os sacrum.

For as it began with the spine (we meane the marrow properly so called) so it determineth therewith, sometimes simple sometimes deuided into three short surcles. For it was necessary that in that part where the spine was especially curued or bent backward or forward, it should be diuersly diuided that it might not be compressed by the vertebra. Hence the reason appeareth why a hurt or annoyance in the lower part of the spinall marrow is worse and more dangerous then in the vpper, because below it is more Nervous, aboue more marrowy.

Now although the Nerves yssuing from the spinall marrow be almost infinite, yet according to the number of the out-lets or holes of the vertebra they are said to bee so many coniugations as the vertebra haue holes. For euery Nerue doth indeed consist of many hairy strings or marrowy fibres, which by the helpe of the Membranes at the holes of the vertebra are conioyned & making as it were a knot doe yssue out of the bone, so that one Nerue seemeth to be made of one propagation, [tab. 16, the figure sheweth it at LL] which thing as it is true in those Nerves which proceede out of the Marrow whilst it is simple and single, so is it also in them which after the diuision are distributed into the lower parts. [table 16, fig. 1, as MM.]

How it may
be said to be
deuided and
where.

Whereof his
nerves are
made & how
they yssue.

TABVLA. XVI.

To put an end to our description of the spinall marrow, we will take leave to insert in this place a description thereof out of *Rondeletius* and *Laurentius*, which is on this manner. All the Nerues, (saith *Rondeletius*) which no man before me hath obserued, are diuided from the very beginning of the spinall marrow in the Braine. Wherefore the cause of the Paralysis or Palsie doth not so much proceed from the marrow of the backe as from the very heads of the sinewes; and thence it is that *Galen* so often repeateth that the Palsie hapneth when the heads of the sinewes are eyther obstructed or resolued. Thus *Rondeletius* hath it in his chap. of the Palsie. *Laurentius* thus: All Anatomistes haue hitherto beene ignorant of the originall and propagation of the Nerues of the spinal marrow, for they all thinke that the nerues of the necke come onely from the marrow of the necke; the nerues of the backe from the marrow of the backe, and of the Loynes from the marrow of the Loynes. But how miserably they haue bin mistaken, is conuincd by a new and vnheard of obseruation of mine owne. Separate therefore the marrow from the rack-bones but keepe it whole, then take from it both the Membranes wherewith it is compassed, cast it into water and shake it a little, and you shall perceiue that the whole marrow from the top to the bottome is made of innumerable furdles and filaments, like a Horse taylor composed of infinite hayres; and that the nerues of os *sacrum* do arise from the same beginning with the nerues that are aboue. This new and admirable obseruation maketh plaine an obscure probleme, why, when the marrow of the necke is offended the motion of the thigh is sometimes taken away, when as the motion of the armes and of the Chest is not at all vitiated; thus for *Laurentius*. To conclude.

The vse of the spinal marrow properly so called, is saith *Galen* in his twelfth Book *de usu partium*, that from it as from another braine there should proceed many nerues as it were small riuers which might conuey the Animall faculty, sense, motion and the Animall spirit; which they receiue by continuation from the braine (to the parts vnder the head) excepting those whereto are transmitted certaine propagations from the sixt paire [tab. 17, fig. 1, and 2, e] of the marrow of the braine, which also are disseminated through the middle and lower bellies. For, because it was not safe, in consideration of the length of the way, that all the nerues should bee transported vnto the inferior parts from the marrow of the braine contained in the Scull; and yet it was necessary that those inferior parts should be supplied with voluntary motion and sence to apprehend annoyances: it was most requisite that from this marrow, as from the braine elongated or produced, those sinewes should be deriued; for if a man had wanted motion hee had beene more like an Image then a creature. And thus much of the vse of the marrow properly so called. But if you take it in the larger signification, then the vse of it is, that from it where it is included within the scull on both sides should yssue seauen coniugations or payres of nerues, (as is commonly thought) we say eight, which are called the nerues of the braine, [tab. 15, fig. 20, BGHIKMNO] together with the Organs of smelling. [Tab. 14, fig. 19, D E] But as it consisteth in the spine without the Scull there are produced therefrom thirty paire [tab. 16, fig. 1] euen all the nerues that passe through the whole body. And thus much of both the braines and spinall marrow, now it followeth that we should intreat of the nerues yssuing therefrom.

CHAP. XVI.

Of the Nerues of the Braine, and first, of the Organs of smelling, called processus Mammillares.

THE Nature of the Braine, the After-braine and the Spinall Marrow being thus manifested, it remaineth that we should speake of the Nerues proceeding from each of them; and first of the Nerues of the braine. Whereas therefore there are five outward senses, the Sight, the Smell, the Hearing, the Taste and the Touching, which from the Braine it selfe or rather from the Marrow thereof doe receiue by nerues as it were by Channels some of them the faculty of Sensation alone, some of them of Sensation and motion together, which nerues are sayed thence to arise as from a principle of dispensation and radiation, from whence they bring the Sensatiue and mouing faculties of the Soule to the instruments of the Sences: it is very fit that in this place we should deliuer their history. Wee will therefore begin with the Organs of smelling. Although the Nose bee the way and path of smells, yet is not the instrument of smelling, neither yet his hindmost coate; but farther within the skull there are certaine processes or productions esteemed for the very organs of this sence, which the Anatomists looking onely vpon their prominent part haue called Pro-

Table 17, Figure 1, Sheweth the Basis of the Braine and After-braine freed from their membrane, that the originall of the Nerves of the braine might be better perceived. Figure 2. Sheweth one side of the Braine, the After-braine, the spinall marrow and the Nerves.

TABVL A. XVII.

FIG. I.

FIG. II.

may be accounted for a distinct nerve. *b* 1, 2, a small branch deriued from this harder part of the first paire. *c* 1, 2, a lower branch from the same originall. *d* 1, 2, this nerve is commonly ascribed to the sixth payre, but indeed is a distinct coniugation which we will call the Eight, because we would not interrupt the order of other mens accounts. *e* 1, 2, the sixth paire of sinewes. *f* 2, a branch from them deriued to the necke and the muscles couched thereupon. *g* 2, another branch to the muscles of the larynx or throtle. *h* 1, 2, the seuenth paire of sinewes. *i* 1, the vnion of the seuenth paire with the sixt. *l* 2, a propagation of the seauenth paire to those muscles which arise from the appendix called *Styloides*. *m* 2, Surcles from the seauenth coniugation to the muscles of the tongue, the bone *Hyois* and the Larynx. *opq* 1, three holes; through the hole *o* the phlegme yssueth out of the third ventricle of the braine to the Tunnell, and at *pq* is the passage of the *soporary* arteries to the ventricles of the braine.

cessus mammillares, and some the organs of smelling. Vnder which Title *Galen* hath written of them at large. These are two something like nerves but scituated in the Basis of the braine; they are whiter, softer & broder then nerves are. Notwithstanding like nerves they are round and slender. In men they are very small; in beastes as Oxen, Goates, Sheepe and Dogs, they are much larger, whence it is that all these Creatures haue this sence of smelling more exquisite then men.

These processes arising out of the marrowey substance of the braine in his Basis [tab. 17, fig. 1, and 2 F. tab. 14, fig. 19. D P] neare the opticke nerves [tab. 17, fig. 1, 2. G] do passe betwixt the braine, (whereto they are tyed by the mediation of the *pia mater*) the wedge bone & the bone

Why beastes

then men.
Their origi-
nall.

AA 1, 2. The braine.

BB 1, 2. The After-braine.

CC 1, 2, the swelling of the braine which some call the mammillary processes.

D 1, the beginning of the spinall marrow out of the Basis of the braine.

E 1, 2, a part of the spinall marrow when it is ready to yssue out of the skull.

FF 1, 2, the mammillary processes which serue for the sence of Smelling.

GG 1, 2, the opticke nerves.

H 1, the coition or vnion of the opticke nerves.

II 1, 2, the coate of the eye whereinto the optick nerve is extended.

KK 1, 2, the second paire of the sinewes, ordained for the motion of the eyes.

LL 1, 2, the third paire of sinewes, or according to the most Anatomists, the lesser roote of the third paire.

MM 1, 2, the fourth paire of sinewes, or the greater roote of the third paire.

N 2, a branch of the third coniugation deriued to the musculous skin of the forehead.

O 2, a branch of the same to the vpper iaw.

PP 2, another into the coate of the nosethrills.

Q 2, another into the temporall muscles.

R 2, a branch of the fourth coniugation crumpled like the tendrill of a vine.

S 2, a branch of the same reaching vnto the vpper teeth and the gummies.

T 2, another of the same to the lower iaw.

V 2, a Scurcle of the branch *T*, to the lower lip.

XX 2, another surcle from the branch *T*, to the rootes of the lower teeth.

YY 2, the assumption of the nerves of the fourth coniugation vnto the coate of the tongue.

Z 1, 2, the fourth paire vulgarly so called which are spent into the coates of the palat.

a 1, 2, the fift paire of sinewes which belong to the hearing.

q, the Auditory nerve spread abroad into the cavity of the stony bone. * a hard part of the fift coniugation about the * which

bone of the forehead vnto the *Sinus* or cauities of the spongy bone, [tab. 14, fig. 19, HF] which cauities are couered with the *dura meninx* diuersly perforated and are made to receiue these productions. To each of these processes saith *Fallopins* reacheth a manifest hole from the ventricle, from which hole the passage is open to the spongy bone. This passage in a man is very narrow, so that it cannot be discerned, but when the head is very greene or new. In Oxen it is very large. Through these passages and productions aire & vapors attracted or drawne in respiration through the nostrils as it were by pipes and channels, are carried vnto the brain that it might iudge of odoriferous objects. *Varolius* is of opinion that from these productions there is no free passage vnto the ventricles themselves; although *Fallopins* was vicerly of another minde. They are like to nerves in their passage, colour and vse, and therefore do well deserue to be called the *Nerves of smelling* as *Archangelus* stileth them. But *Vesalius* counteth them to be the first paire or coniugation of the braine, yet because they neuer attaine through the thicke membrane and cauity of the skull, neither haue as other nerves any propagations deriued from them: therefore neither *Herophilus* nor *Marinus* nor *Galen* himselte, nor many amongst the *Neotericks* or new writers haue vouchsafed them the name of nerves; wee stand not vpon words and therefore passe from them vnto the nerves of the eies.

Their vse.

How they may be called nerves.

CHAP. XVII.

Of the nerves of the Eies, or of the first and second Coniugations.

¶ Lbeit in a particular discourse hereafter following wee intend more districly and carefully to prosecute the Nature and diuarcations of nerves in generall and euery one in particular; yet because all the nerves of the head haue their originall from diuers partes of the substance of the same: Wee cannot chuse in this place but make some mention of them though it be the briefer.

The first coniugation therefore of the nerves of the braine are the Opticks, [Table 15, fig. 7 1, and 2, G] larger and softer then all other simple nerves. Larger because they bee sensibly perforated, softer because they arise out of the Center of the Basis, whence proceeding forward with a slow course they are vnited aboue the saddle of the wedge-bone [Tab. 17, fig. 1, H, table 14, fig. 19, O] and so make a common body. After being againe separated [tab. 14, fig. 19, MN, tab. 17, fig. 1, aboue H] they passe obliquely forward through their proper holes [table 4, fig. 10, B] the one to the Center of the right eye, the other to the Center of the left [tab. 3, lib. 8, fig. 8, a, or together with the membrane fig. 2, a b c.]

The opticke nerves.

They consist of a double substance, the one marrowey the other membranous. The marrowey is soft like the substance of the braine, which you shall perceiue to yssue if it bee hard pressed, and of this marrowey substance dilated in the orbe of the eye is that coat made which of the similitude of a net is called *Retina tunica* [Tab. 17, fig. 1, and 2, I] and this compasseth the glassy humour like a spheare

Their double substance. Marrowey.

They haue two membranes from the two Meninges of the braine. The thinne membrane inuesteth them frō their original to their out-let from the skull; the thicke Meninx is added to them, from thence to the eye; and so the thicke membrane degenerateth into the horny coat, the thinne is consumed or spent in the *Vnea*, & so the Animall spirit is transported through the continuation of this nerve vnto the *pupilla* or Apple, which is the hole of the grapy membrane.

Their membranes.

They are called therefore Opticke nerves from their action, because they communicate to the eye the sence of seeing.

The second coniugation is of the nerves which moue the eyes, [tab. 18, fig. 1, and 2 K, tab. 15, fig. 20, G] which is distinguished from the former onely by a little and thin bone, & riseth from the the Basis of the braine [tab. 25, fig. 1, e] a little behinde the former as *Vesalius* saith. This paire is smaller and slenderer by much then is the opticke, as also harder because it was to be inserted into the muscles. It yssueth by a proper hole of his owne [tab. 4, fig. 10, G] which is the second of the wedge-bone, where after it is diuided into notable branches which are sent into the muscles. In some bodies (though it be but seldom) they send small twigs to the temporall muscles; whence it is that sometimes if that muscle be offended, the eie also suffereth with it, and so on the contrary.

The 2. coniugation of the mouing nerves. Their frame.

Note this.

Their vse is to afford to the muscles the facultie of Motion, as also a drawing power to their membranes. Now the reason why when one eie is moued to the side the other also necessarily followeth, is, because these nerves are continued one with another in their originall.

Their vse. Why both eies moue together.

CHAP. XVIII.

Of the third and fourth Coniugations of the Nerves of the Braine.

The 3. Coniugation,

HE third Coniugation [tab. 19, fig. 1, and 2, L. tab. 15, fig. 20, H] is sent vnto the Muscles of the face, and is commonly called the smaller roote of the third paire, but it deserueth, wee thinke, to bee a particular coniugation, because it is not ioyned with the following paire [tab. 15, fig. 20, I. tab. 19, fig. 1 and 2, L. with M] neyther in his beginning nor in his progresse.

His Original,

Issue,

4. Branches.

It ariseth from the lower and backer part of the marrow of the Braine. It is very small and perforateth the *dura Meninx* at the side of the basis of the Braine where it is fastned to the second coniugation [table 19, Fig. 1, K] and so with it yssueth into the orbe of the eye by the hole common to them both [tab. 3, Fig. 8, G] Then it is diuided into foure branches: the first [tab. 19, Fig. 2, N] ascendeth vpward by the fat of the eye and yssueth at a hole of the forehead bone proper vnto it [tab. 3, Fig. 8, A] and so passeth into the skinne of the Forehead to which it giueth motion, as also to the vpper eye-brow.

The second descendeth [tab. 19, Fig. 2, O] and passeth through a hole of his owne, bored in the fourth bone of the vpper law [tab. 3, Fig. 8, B] and so is dispersed into the Muscles of the vpper lip, into those that mooue the wing of the Nose outward, into the tip it selfe and some of the gummies.

The third branch [table 19, Fig. 2, P] passeth through the second hole of the vpper law [tab. 3, Fig. 8, C] and attaineth into the Cavity of the Nosthilles and is spent into their coate, [table 19, Fig. 2, the lower P] and affordeth a small surcle to the membranous Muscle which contracteth the wing of the nose.

The fourth branch [tab. 19, Fig. 2, Q] being led through the Fissure which is betwixt the bone of the vpper law and the Wedge-bone [tab. 3, Fig. 8, D] is spent into the inner part of the temporall muscles.

The fourth Coniugation,

The reason of his originall.

The Fourth Coniugation are the Nerves of Tasting, Tab. 19, Fig. 1, and 2. M. Tab. 15, Fig. 20, I] it beareth on the former in his progresse but not in his originall. It proceedeth not out of the backparts of the braine because they are hard; not out of the sides because their way would not haue bin safe; but out of the basis yea the very Marrow of the Braine [tab. 25, fig. 1, char. 3] aswell for security as because of the Situation of the tongue.

Where it yssueth.

It hath three branches.

It yssueth at the first hole of the wedge-bone [tab. 3, fig. 9, Q] and presently sendeth a Surcle out of it like the crumpled Tendrill of a Vine, in which the Animall spirit maketh some stay. Afterwards, it is by two branches vnited to the Nerue of Hearing, [tab. 19, fig. 1, 2, bc] & so is disseminated into the muscles of the face, the Temporall, the grinding Muscles of the Cheekes and to the skinne of the face.

A second branch it also parteth with [tab. 19, fig. 2, S] which affordeth surcles to that part of the Gummies wherein the grinding Teeth are fastened, yea vnto the teeth themselues.

TABVLA. XIX.

FIG. I.

FIG. II.

A third branch also sprowteth out of the back-part, [table 19, Fig. 2, T] which is inserted into the muscles that lurketh within the mouth, and passeth through the inner hole [tab. 11, lib. 8, fig. 2, F] of the lower Jaw, and there offereth surcles to the Rootes of the lower teeth of the same side. [table 19, Fig. 2, XX] and by their helpe the teeth haue sense, whereas the other bones haue none.

How the teeth haue sense.

Finally, the Trunke it selfe [table 19, Fig. 2, T] passing through the muscles lurking in the mouth together with the Trunke of the other side attaine to the sides of the tongue and are consumed in his coate to make it a conuenient Organ of Gustation.

CHAP. XIX.

Of the Nerues of hearing, or of the first Coniugation of the Braine.

THE first Coniugation [Table 20, Fig. 1, and 2, Tab. 15, Fig. 20, M] ariseth out of the Marrow of the Braine lengthened, where it ioyneth with the *Cerebellum*. [Tab. 25, Fig. 1, i] There his originall seemeth to be out of two Surcles or Nerues, the one softer the other harder, which together perforate the membrane and passe to the stony bone.

The first Coniugation.

His 2. Surcles.

His out-gate.

This Nerue passeth through a notable writhen hole thrilled in the stony-bone, which they call the first hole of the Temple bone, where it meeteth with that cavity which is compared to a Connyborough and prepared for the Organ of hearing. Afterward the harder part falleth into the cavity where the *Tympanum* or the Drum is placed.

The softer part [Table 20, Fig. 2, a] which is indeed *Nervus auditorius* the sinew of hearing, accompanieth the former, and when it attaineth to the extremity of the aboue named cavity it is dilated like a membrane [tab. 20, Fig. 1, 2, d] and becommeth the speciall Instrument of hearing, and in that place remaineth haply after the same manner that wee said before the Organ of smelling was extended.

The true Organ of hearing.

CHAP. XX.

Of the sixt, seauenth, and eight Coniugations of the Sinewes.

THE sixt Coniugation [tab. 21, fig. 1, and 2, e, tab. 15, fig. 20, N] taketh his beginning of a few fibres a little below the originall of the Nerue of hearing.

That the sixt Coniugation is not one but two Nerues.

These Nerues being instantly vnited doe make one notable Nerue as some haue thought, but indeed they are neuer so vnited but that they remaine two Nerues contained or held together in one membrane, and passe out at one hole, [tab. 4, Fig. 10, b] which is counted the 1. hole of the *Occipitium* or Nowle-bone. The one of those is the forwarder and the lesser: the other the backwarder and the greater. The lesser runneth directly to the muscles of the tongue, and for the most part is spent in the mouth; the greater as soone as it is issued out of the Skull sendeth a branch backward [tab. 21, fig. 2, f] which is diuersly distributed into the *Muncks-hood* muscle of the shoulder blade. The trunke it selfe descending is tyed to the seauenth Coniugation, [tab. 21, Fig. 2, H] and at the sides of the throttle is increased with a branch from that seauenth Coniugation, [table 21, fig. 2, i] with which notwithstanding it is not mingled but onely colligated or tyed: after it sendeth surcles to the muscles of the *Larinx* or throtle, [tab. 21, Fig. 2, g] as also some other smaller to the muscles of the Chops, thence it descendeth to the Chest, where wee will leaue it till another time.

where it issueth.

The course of it.

The seauenth Coniugation [table 21, Fig. 1, h Fig. 2, H] moues the tongue, and is the hardest of all the sinewes proceeding out of the Scull, for it ariseth iust at the place where the marrow of the braine falleth out of the Scull. [tab. 21, Fig. 1, 2, E] It ariseth of many Roots somewhat distant each from other, which ioyning together into one doe passe out of the Scull at an oblique hole bored in the bone of the *Occipitium*, and for more security is ioyned by strong membranes with the sixt Coniugation, yet not mingled therewith. For this seauenth paire keepeth his owne body and so runneth downward to the roots of the tongue, where the most part of it [tab. 21, Fig. 2, Z] is loosened into many fibres which giue motion thereto. Other parts of it are deriued to the muscles of the bone *Hyois* and the Throtle to giue them motion;

The seauenth Coniugation.

His originall.

and course.

motion; some surcles also it sendeth [Tab. 21, fig. 2, 4] to those muscles that arise from the appendix called Styloides.

The eight
Coniugation,

The eight Coniugation [Tab. 21, fig. 1, 2, d, Tab. 15, fig. 10, L] proceedeth out of the marrow of the braine above the Auditory Nerue betwixt the second and third Coniugations.

It perforateth betwixt those 2. paires the thicke Meninx and attayneth into the orbe of the eye through the hole that belongeth to the second coniugation, and is almost wholly spent into that muscle of the eye which draweth it vnto the vter corner.

CHAP. XXI.

Of the Nerves proceeding from the spinall marrow properly so called.

Auing acquainted you with those coniugations of finewes which belong vnto any part of the braine or his productions containd within the Skull, it remaineth now to give you a short viewe of those nerves which are deriued out of the spinall marrow containd in the rack-bones of the Chine. These therefore are accounted to bee 30. paires, all proceeding out of distinct the seuerall parts; that is to say, out of the racks of the neck, the chest, the loines and the holy-bone.

Seauen or 8.
paires of the
Necke.

The Coniugations of the Necke some account seauen, others eight, dispersed into the outside of the whole head and the muscles thereof.

The first Coniugation yssueth betweene the Occipitium or Nowle bone and the first rack-bone, and is diuided into two little branches, a forward and lesser, [Tab. 22, H] and a backward and greater [Tab. 23, F].

The second Coniugation of the Necke hath two originals, a forward [Tab. 22, N] and a backward which is the larger, [Table 23, I] which is diuided into two branches, a thicker [Table 23, K] and a thinner, [Tab. 23, above B].

The 3. paire [Tab. 22, character 3] breaketh out of the common hole betweene the second and the third spondels or racks, and is diuided into two branches, one forward [Tab. 22, P] which is subdivided into foure Surcles. The first at [Tab. 22, Q] The second at [Tab. 22, and 23, R.] The third at [Table 22, S and Table 23, KL] The fourth at [Tab. 22, and 23, T.] Another backward, [Tab. 22, and 23, O] diffeminated into the muscles which are common to the head and the necke.

The fourth Coniugation [Tab. 21, Char. 4] falleth out of the common hole of the third and fourth vertebra, and is diuided into two branches, the first forward and greater, [Tab. 22, and 23, X] which is diuided into three Surcles, the first at Tab. 22, y] the second at Tab. 22, a] the third at Tab. 22, b] The second branch is the lesser and more backward, [Tab. 22, and 23, v] and is spent in the muscles of the Necke and the membranous muscles of the Cheekes.

The fift Coniugation [Tab. 22, char. 5] falleth out vnder the fourth rack-bone, and is diuided into two branches, one forward and another backward, the forward [Tab. 22, and 23, d] hath three Surcles, the first at Tab. 22, a d] the second Tab. 22, e] the third Tab. 22, and 23, f] The backward branch [Tab. 23, a] is distributed as is the backward branch of the fourth paire.

The sixt Coniugation [Tab. 22, char. 6] falleth out vnder the fift racke, and is likewise diuided into a fore and hinder branch: the fore branch at Tab. 22, f] the hinder branch at Tab. 23, k.]

The seuenth Coniugation [Tab. 22, char. 7] yssueth vnder the sixt racke bone of the Necke, and is ioyned with the sixt paire of the Necke and the first of the Chest [Tab. 22, f.] for more security, and the greatest part of it passeth into the arme, which sometimes sendeth a branch to accomplish the Nerue of the Midriff. The backer branch [Tab. 23, e] is the lesse, and is bestowed vpon the muscles lying vpon the necke and vpon the square muscle of the Cheeke, which first suffereth convulsion in the disease called *Spasmus Cynicus*, or the Dog laughter.

Twelve paire
of the Chest.

And thus much of the Nerves proceeding from the spinall marrow contained within the vertebra or spondels of the necke, which we sayde were seauen Coniugations. It followeth now that we should intreate of the nerves proceeding from the marrow of the rack bones of the Thorax or Chest. Of these, there are (as some thinke) but cleauen Coniugations, others resolue of twelue, all which after their outlet are diuided into two branches, one greater, the other lesser, one passing forward, another reflected backward.

The first Coniugation [Table 22, character 8] is shewed betwixt the seuenth bone of the Necke and the first of the Chest. It hath two branches, the first greater sendeth certaine pro-
paga-

pagations to the shoulder blade [*table 13, aa*] and to the first rib: [*tab. 22, y*] The second lesser [*table 23, u*] is disseminated into the adjoining muscles.

The second Coniugation [*tab. 23, char. 9*] yssueth betwixt the first and second bone of the Chest; then it distributeth a branch backward, [*tab. 23, b*] & after is ioyned with a branch of the former Coniugation, [*tab. 23, f*] & so passeth into the arme; that which remaineth of this Coniugation followeth the course of the first rib, and maketh an intercostall Nerue.

The third Coniugation as also all the other nine [*table 22, from char. 10, to 20*] of the Chest are distributed after the same manner. For after they fall out of the sides of the *vertebra* they are diuided into two branches, one forward and another backward; the forward branches are called Intercostales, that is, *betwixt the ribbes*, [*table 22, m*] for from them many branches are disseminated into the Intercostall muscles, [*table 22, 00*] and the characters of the left side into the muscles lying vpon the Chest, [*table 22, 00, 11, n*] as the great and lesser *Saw*, the pectorall and the broad Muscle; [*table 22, mu*] and are strangely reflected to the vessels thereabout. The backward branches leane backward to the spines or sharpe points of the *vertebra*, and are deriued into the muscles which moue the backe of the Chest, and into the skinne of the backe, but their distribution is not in all men alike.

The third and all the rest.

Finally, the two last coniugations of the twelue do send Surcles [*Tab. 22, at the sides of the 18, and 19. Characters*] to the head of the sixt muscle of the thigh.

From the spinall marrow contained in the racks of the loynes doe arise five coniugations greater then the former, deuided like-wise after their out-gate into a forward and a backward branch, and from their backward branches [*Table 23, char. 52, and 53*] send surcles into the muscles which grow to the *vertebra* of the Loynes.

The nerves of the Loynes, five paire.

The first Coniugation [*Table 22, char. 20*] as also al the rest yssue out of the holes of the *vertebra* vnder the *Peritonaeum*, and is diuided into two branches, a greater and *anterior* partly ascending to the *Diaphragma*, partly to the muscles of the *Abdomen* or paunch; and a lesser and *posterior* which is reflected into the muscles which leane vpon the *vertebra* of the Loynes.

The second Coniugation [*table 22, char. 21*] runneth vnder the sixt muscle of the thighe and riseth to the top of the haunch bone, but the forward branch is distributed to the sixth internall Iliacke, and the first bender of the legge. It sendeth also a small long nerue [*table 22, char. 49*] accompanying the spermaticall vessels of the same side euen vnto the Testicle.

The third coniugation [*table 22, char. 22*] yssueth also vnder the Lumball muscle; the fore-branch passeth neare the haunch-bone and is deuided into two propagations, one going to the knee the other accompanying the veine called *Saphena*; but the back branch is reflected and disseminated into the muscles lying vpon the loynes and into the skinne. So likewise from all the foure-branches of the three first coniugations certaine shootes [*table 22, at the sides of the 20, 21, 22. Characters*] doe attaine to the costall nerue, and are ioyned therewith.

The fourth coniugation [*table 22, char. 23*] which is the biggest of all the coniugations of the loynes accompanieth the veines and arteries to the groine, and distributeth certaine surcles to the forward muscles of the thigh and the leg.

The fift coniugation [*table 22, char. 24*] is parted in twaine as are the former. The fore-branch and the greater passeth through a hole betwixt the *Coxa*, the share-bone & the branch-bone and sendeth diuers shootes to the muscles of the thigh, the yarde, the necke of the wombe also and the bladder; but the backe-branch is reflected to the muscles that leane vpon the *vertebra* of the loynes and into the skin thereabouts. Furthermore, these coniugations are tyed one vnto another, the first to the second, the second to the third, the third with the fourth, and the fourth with the fift, as is shewed in the first figure of the 22. Table.

To conclude, out of the marrow conteyned in the *vertebra* of the *Os sacrum* or holy-bone do proceed sixe coniugations.

The nerves of the Os sacrum.

The first [*table 22, char. 25*] yssueth betwixt the last of the loyne and the first racke of the holy-bone, and is diuided into a fore-branch and a hind-branch; the fore-branch sendeth a surcle [*table 22, character 23*] into the inside of the haunch-bone, from which certaine shootes are offered to the muscles of the *Abdomen*, and the seuenth muscle of the thigh. The backe-branch passeth in a like course as do the back-branches of the other coniugations and a shoot beside into the muscles [*table 23, char. 54*] produced from the haunch-bone, specially into the first mouing the thigh, from whence it is consumed into the skin.

The five other Coniugations [*table 22, from the 26. to the 30. charact.*] are produced after another manner; for before they yssue they are double on either side; one proceeding forward and another backward. Of the fore-branches the three vppermost runne to the legge, the

The other five.

Table 22. and Table 23. Because the same Characters belong to them both, we have set them together.

Table 22. sheweth the Racks of the spine and the nerves yssuing there from on the fore side.

Table 23. sheweth the same Racks and Nerves on the back side.

TABVLA XXII. & XXIII.

A 1, 2. The spinall marrow as it goeth into the racke-bones. *BC 2.* The seaven vertebrae or racke-bones of the necke: Character from 1, 2, to 30. in the 15. table do shew the racks of the whole spine. *CD 2.* amongst these the twelue racks of the Chest. *DE 2.* The five Racks of the Loynes. *E 2.* The holy bone. *F 2.* the hinder branch of the first coniugation of sinewes. *G 1, 2.* the distribution of the same branch into the muscles of the head. *H 1,* the foreward branch of the first coniugation. *I 2,* a small branch of the hinder propagation of the second paire which is distributed vpward. *K,* a thicker branch of the same nerve. *L 2,* the coition or coniunction of the branch of the third paire, with the branch of the second paire marked with *K.* *MM 1, 2,* the second paire distributed vnto the skinne of the head as farre as to the necke. *N 1.* The anterior branch of the second paire. Character 3. in the first Table sheweth the third coniugation and the third rack-bone. *O 1, 2.* The hinder branch of the third paire reflected first backward, then forward vnto the muscles: and such a reflection there is in all the nerves vnto Character 24. *P 1.* the anterior branch of the third paire parted into foure. *Q 1,* the first going vnto the muscles. *R 1, 2.* The second ioyning with the fourth paire. *S 1,* The third commixed with the branch *K.* *T 1, 2.* The fourth branch going to the muscles of that place. Character 4. in 1, the fourth coniugation of the fourth rack-bone. *V 1, 2.* The Posterior branch of the 4. paire. *X 1, 2.* The anterior branch of the 4. paire parted into three. *Y 1.* The first admitting the branch *R.* *a 1,* the second going to the muscles. *b 1,* the 3. reaching to a part of the first paire marked with *e.* Character 5. in 1, the 5. paire. *c 2,* the posterior branch of the 5. payre. *d 1, 2,* the anterior branch of the 5. paire. *e 1,* this portion maketh the nerue of the midriffe. *f 1, 2,* a branch of the nerue *d* creeping along the top of the shoulder, vnder which are certaine surcles attaining to the shoulder-blade. *g 1, 2,* a surcle of the nerue *f* deriued to the skin on the top of the shoulder. *h 1, 2* a surcle of the nerue *f* going to the second muscle of the arme. *i 1, 2,* another branch inserted into the same muscle and the skin. Character 6. in 1, the sixt paire. *k 2,* the posterior branch of the same sixt coniugation. *l 1,* the anterior branch of the same coniugation. *m 1,* a surcle of the same nerue appointed to make vp the Sinew of the midriffe. *n 1, 2,* the nerue of the midriffe made of three surcles. *b, b,* and *m.* *oo 1, 2,* the insertion of

of this nerve into the midriffe. *p. 2*, A branch of the sixth coniugation running to the cavity of the shoulder blade. *q. 1, 2* The coniugation or implication of the branch *l*, with the branches neighbouring about it. Char. 7. in 1, The 7. coniugation of sinews. *r. 2*, The *Posterior* branch of the 7. paire. *s. 1*, The congresse or meeting of the 7. coniugation with the branches that are neere it. *tt. 2*, Surcles of this nerve deriued to the muscles of the shoulder blade and the arme. Char. 8. in 1, The 8. coniugation or the first paire of the Chest running about the first rackbone of the Chest. *u. 2*, The *posterior* branch of the 8. paire. *x. 1, 2*, The coition or coniugation of the 8. paire with the 7. *y. 1*, A branch of the 8. paire reaching to the top of the breast. *aa. 2*, Surcles proceeding from the 8. coniugation and deriued to the muscles in this place. char. 9. in 1, The 9. paire of nerves. *β. 2*, The *Posterior* branch of the 9. paire. *δ. 1*, The *anterior* branch of the same coniugation. *ζ. 1*, Surcles from this branch to the distances or spaces of the Chest. Char. 10. to 20. in 1, The paires of sinews deriued to the distances betwixt the ribs. *nn. 1*, Surcles of the intercostall sinews going to the roots of the ribs and increasing the *Costal* nerves. *θ θ. 1*, Branches from the intercostall sinews deriued vnto the muscles which lye vpon the Chest. *11. 1*, Branches going to the pectorall muscle or the first muscle of the arme. *κ κ. 1*, Other branches going to the lower side of the same muscle. *λ λ. 1*, Branches going to the oblique muscles of the *Abdomen*. *μ μ. 1*, Others deriued to that muscle of the arme which is called *Latissimus*. *ν. 1*, A branch passing vnto the *Pap. o o. 1*, Branches from 18. and 19. to the beginning of that muscle of the thigh which is called *Lumbalis* or the sixth muscle of the thigh. *π π. 1*, The first nerve of the arme distributed into the skin. *ρ. 1, 2*, The second nerve of the arme. *σ σ. 1*, From this doe nerves passe to the first muscle of the cubite called *Biceps*. *τ. 1, 2*, The third nerve of the arme. *υ. 1, 2*, A branch of the same going to the skin of the arme. *φ. 1*, A small branch deriued to the second muscle of the cubite called *Brachialis*. *χ. 1*, Others passing to the skin on the fore side of the arme. *ψ. 1*, The congresse or coniugation of the third nerve with the second. *ω. 1*, The 2. and the 3. nerves after their coniugation doe heere creepe downeward. *1. 1*, a nerve deriued vnto the second muscle of the *Radius* which muscle is called *supinator longior*. *Δ Δ. 1*, The vpper branch of the 2. nerve, running to the wrist and to the first joint of the thumbe. *Θ. 1*, The middle branch of the 2. nerve. *Α. 1*, The progresse of the same euen vnto the hand. *Ξ. 1*, The lower branch of the 2. nerve. *Π Σ. 1*, Two branches of the same nerve going to the inside of the hand. *Φ. 1, 2*, The 4. nerve of the arme. *τ. 2*, From hence do proceede nerves to the muscles which extend or stretch out the cubite. *Ω. 2*, A branch going to the skin of the arme on the backside. *32. 2*, Branches deriued to the outward skin of the arme. *34. 2*, The by partition of the fourth nerve at the cubite. *33. 2*, A branch creeping along the outside of the cubite euen vnto the wrist. *35. 2*, The vpper branch of the foresaide diuision. *36. 2*, Surcles belonging to the thumbe, the forefinger and the middle finger on their out sides. *37. 2*, The lower branch of the foresaide diuision. *38. 2*, Surcles heerefrom to the muscles arising out of the externall bunch of the shoulder bone. *39. 40. 41. 2*, Three branches going to the muscles which spring from the bone called *Vlna*. *42. 2*, The end of the branch, *37*. neere the joint of the wrist. **. 1, 2*, The fift nerve of the arme. *43. 1*, Surcles of the 3. and 5. nerves to the inside of the cubite. *44. 1*, A branch of the 3. nerve going to the palme of the hand and the fingers. *45. 1*, A branch of the 5. nerve to the inside of the hand. *46. 1*, A surcle of the branch *45*, led to the outside of the hand. *8. 1, 2*, The 6. nerve of the arme. *47. 1*, The end thereof next the joint. *48. 48. 1*, Surcles from the 6. nerve vnto the skin. Char. 20. to 24. 1, Nerves proceeding out of the racks of the loynes. *49. 49. 1*, A branch going into the Testicles from the 20. paire. *50. 50. 1*, The nerves belonging to the muscles of the *Abdomen*. *51. 1*, Surcles from these to the broad muscle of the arme called *Latissimus*. *52. 52. 2*, The backward branches proceeding out of the racks of the Loynes. Char. 25. to 30. The coniugations or paires of sinews proceeding out of the holy bone. *53. 1*, A branch of the 25. paire going to the inside of the *Coxendix* or hip-bone. *54. 55. 2*, A branch attaining to the outside of the *Coxendix*. **. 2*, Hence proceedeth a nerve communicated to the yard. *56. 2*, The end of the spinall marrow. *57. 1*, The first nerve of the leg. *58. 1*, Branches heerefrom to the skin. *59. 1*, Other branches heerefrom to the muscles. *60. 1*, The 2. nerve of the Leg. *61. 1*, Branches heerefrom to the skin. *62. 1*, A branch descending to the top of the foot. *63. 1*, Branches from *61*. compassing the knee. *64. 1*, A branch of the 2. nerve going to the muscles. *65. 1*, a branch heerefrom going to the 5. muscle of the thigh called *Triceps*. *66. 1*, The nerve of the Leg. *67. 1*, A surcle creeping to the hole of the share-bone. *68. 1*, A branch allowed to the skin on the inside of the thigh. *69. 1*, A portion of the 3. nerve going to the muscles. *70. 1*, A portion hereof communicated to the 2. muscle which bendeth the leg or *Tibia*. *71. 1, 2*, The 4. nerve of the leg. *72. 1, 2*, A branch hereof communicated to the skin of the thigh in the backpart. *73. 1*, Another to the muscles which arise from the *Coxendix*. *74. 1*, A branch allowed to the 4. muscle of the *Tibia* or leg and to the skin. *75. 1*, Surcles from the 4. to the heads of the muscles of the foot. *76. 1*, The diuision of the 4. nerve in the Ham into 2. Trunkes. *77. 1*, The outward trunk. *78. 78. 1*, A branch heerefrom to the skin of the leg or *Tibia* on the outside as farre as to the little toe. *79. 1*, Another branch inserted into the muscles. *80. 1*, A branch dispersed into the skin of the fore side of the leg from the branch. *79. 81. 1*, A part of the branch *79*. going to the muscles of the foot. *82. 1*, The inner trunk of the 4. Nerve. *83. 83. 1*, A branch creeping along the inside of the leg vnder the skin. *84. 1*, A branch of the trunk. *82*. disposed vnder the skin to the back-side of the Calf of the leg. *85. 85. 1*, A branch of the trunk. *82*. creeping along the fore side of the leg to the vpper part of the foot. *86. 1*, A branch of the trunk *82*. passing along the backside of the legge and distributed to the muscles. *87. 1*, The remainder of the inner trunk allowed to the toes.

the two lowermost are diuersly distributed into the muscles of the fundament and the bladder and parts thereabouts. But the back-branches [*tab. 23. char. 54. & 55.*] are distributed into the muscles on the backside of the hanch and holy bones, and into the skin of the buttocks.

Finally, the end of the spinall marrow [*tab. 22. and 23. char. 56.*] proceeding from the holy bone sendeth one propagation on either side, which is sometimes diuersly diuicuated and disseminated into the fourth muscle of the thigh, and the skin betwixt the buttocks and the fundament. Notwithstanding in Dogs and Apes there are three coniugations proceeding out of the Coccyx or rump-bone.

Wherefore to summe vp all, we must remember that the spinall marrow hath 30. paire or coniugations of sinews; seuen belonging to the marrow of the necke, twelue to the marrow of the backe, siue to the marrow of the loynes and six to the marrow of the holy-bone: all

The vse of
this chapter.

Table 24. sheweth the Braine together with the After-braine, the spinall marrow and the Nerves of the whole body.

TABVLA XXIV.

- A, That part of the braine that is next the noſethrills.
 B, That part which is at the ſide of the ventricles.
 C, The back part of the braine.
 D, The *Cerebellum* or After-braine.
 E, The Mammillary proceſſe in the right ſide.
 F, The originall of the opticke nerve.
 G, Their coniunctions.
 H, The coare into which the optick nerve is extended.
 I, The ſecond paire of the ſinews of the braine.
 K, The leſſer roote of the third coniugation. (opinion:
 L, the thick roote of the ſame coniugation according to the common
 M, The fourth coniugation of the ſinews.
 N, The leſſer roote of the fiſt paire.
 O, The bigger roote of the ſame paire.
 P, The ſmall membrane of the eare which they call the *Tympany*.
 Q, The lower branch of the bigger roote of the fiſt coniugation.
 S, The ſixt paire of ſinews.
 T, The ſeuenth paire.
 V, The beginning of the ſpinall marrow out of the middle of the ba-
 ſis of the braine.
 X, The right ſinew of the midriffe cut off.
 Y, A branch from the fiſt paire creeping to the top of the ſhoulder.
 Z, The fiſt nerve of the arme from whence there goeth a branch to
 the ſkin.
 A, The ſecond nerve of the arme, and a branch therefrom into the
 fiſt muſcle of the Cubite.
 B, The third nerve of the arme and a branch going to the ſkin on
 the outſide.
 C, A branch from the 3. nerve to the 2. muſcle of the Cubite.
 D, The congreſſe or meeting of the ſecond nerve with the third.
 E, A ſmall branch from the 3. nerve to the 2. muſcle of the *Radins*.
 F, The diſtribution of the ſecond nerve into two branches.
 * The leſſer branch of this diuiſion lengthened out to the ſkin as far
 as the thumb.
 a, The place of the ſpinall marrow where it iſſueth out of the braine.
 1, 2, 3, &c. Thirty paires of nerves ariſing from the ſpinall marrow
 are here noted by their Char. that is to ſay, 7, of the neck, 12, of
 the Cheſt, 5, of the loynes, and 6, of the holy-bone.
 b, The thicker branch of the 2. nerve diuided into 2. parts.
 c, Branches of the 3. nerve ſprinkled here and there.
 d, Nerves from the third paire to the thumb, the forefinger and the middle finger. ee, The 4. nerve of the arme. f, The paſ-
 ſage hereof through the inſide of the ſhoulder. g, A tripartition of this branch where it toucheth the Cubite. hh, A branch
 diſtributed from the 4. nerve to the outward ſkin of the Cubite. i, the vpper branch of the diuiſion of the 4. nerve. kk, A
 branch of i, reaching to the outſide of the hand. ll, the lower branch of the diuiſion of the 4. nerve paſſing through the back-
 ſide of the Cubite. m, the 5. nerve of the arme. n, Branches of this nerve diſperſed heere and there. oo, A branch of the 5.
 nerve reaching to the inſide of the hand and the fingers. p, A ſurcle of the branch o, deriued to the outſide of the hand and
 the fingers. qq, the 6. nerve of the arme and the courſe thereof vnder the ſkin. rr, the intercoſtall nerves there cut off where
 they are together with the ribs reflected forward. ſſ, branches on each ſide running backward. tt, Nerves attaining vnto
 the Cheſt. uu, the commixtion of the nerves rr, with the deſcending branch of the 6. coniugation of the braine. xx, Nerves
 from the loynes led vnto this place. y, A branch going to the teſticle here cut off. z, A nerve reaching to the 1. muſcle of the
 thigh. e, the 1. nerve of the leg. aβ, A ſurcle of the former nerve deriued to the ſkin at a and inſerted into the muſcles at β.
 γ, the 2. nerve of the leg. δδ, A nerve from the former, allowed vnto the ſkin as low as to the foot, and paſſing along the
 inſide of the leg. ε, a branch of the 2. nerve running vnto the muſcles. ζ, the third nerve of the leg. η, a ſurcle thereof vnto
 the ſkin. θ, another ſurcle vnto the muſcles. ιι, the 4. nerve of the leg. κκ, the anterior propagations of the nerves proce-
 ding from the holy-bone. λ, the end of the ſpinall marrow. μ, a branch from the 4. nerve inſerted into the muſcles ariſing
 from the *Coxendix* or hip bone. ν, another branch going to the ſkin of the thigh on the backſide. ξ, a propagation deriued
 to the 4. muſcle of the leg and to the ſkin of the knee. οο, nerves attaining to the heads of the muſcles of the foote. ππ, the
 diuiſion of the 4. crurall nerve into two trunks. σ, a branch from the trunk π, diſperſed into the outward ſkin of the leg. τ,
 a ſurcle of the trunk π, deriued to the muſcles. υ, another ſurcle to the ſkin of the leg on the foreſide. φφ, a branch of the
 trunk σ, to the ſkin of the inſide of the leg and of the foot. χ, a ſurcle of the trunk σ, to the hindmoſt ſkin of the leg. ψ, a
 branch of the whole trunk σ, led along to the forward part of the leg and the foot. ω, the deſcent of the trunk σ, into the
 foot.

which it is very necessary a Physition and Surgion should know, that he may be able to apply Oyntments, Cataplasmes and such like to the proper parts of the spine, when the nowle of the head, the face, the neck, the hands, the parts of the Chest, the muscles of the *Abdomen*, the wombe, the bladder, the fundament, the yard or the legges are depriued of sence or motion or both together.

CHAP. XXII.

Varolius his manner of dissecting the Head.

Here is in the body of man so great variety of all manner of parts, that it is impossible to follow the trace of nature by humane diligence so neerly that a man shal not sometimes wander out of his way or be at losse. It is therefore no wonder if the ancient and first Anatomists (men questionlesse very oculte and sharp sighted) did not yet attaine to the exquisite knowledge of all particulars, but left many things to be found out and perfected by their Successors. Nay we assure our selues that no proccesses of time, diligence of inquisition or helps of other mens labours shall euer be able to bring Anatomy to such perfection, but that there will be place left for them that come after to finde out something neuer before discovered; so like is this little world of mans body to the great globe of the Vniuerse, wherein every day new Countries and Nations, yea populous and rich states and Common-wealthes are by traouellers found out. An instance hereof in the Art we haue in hand is *Constantinus Varolius*, who in the yeere 1570. inuented a new manner of dissection of the braine, which how it is accomplished as we haue partly learned by his Epistles written *An. 1573.* partly by our owne dissection saith *Banhsine*, for these 24. yeeres together, we wil here relate, because it doth better exhibite the true originall of the spinall marrow and the nerues proceeding there from, as also the structure of the ventricles for our better satisfaction in the causes of the diseases of the head and the explaining of some passages in *Hippocrates* and *Galen*.

Varolius his
intention.

The difference betwixt these 2. Administrations is; that in the former, the vpper parts of the skull and the Meninges of the braine being remoued, the containd parts are layd open to the view. But in this which is full of labour and difficulty, the bones of the head are on euery side remoued; and the parts contained within the skull yet covered with both the membranes hauiug the eyes, the coniugations of the sinews and the spinall marrow ioyned thereto; are at one view represented and the Section begun at the basis of the braine. But for this Administration the head must be greene & not waterish, otherwise we shall loose our labour: you must therefore take the head of a man newly cutte off, or for want thereof a Calues head will serue the turne, because all the particulars may be therein discerned.

How admini-
stred.

Of the Spinall Marrow.

First of all we must begin at the *Spinall Marrow* which they say ariseth from the lower Basis of the braine at the great hole of the *Occipitium* or nowle bone. [tab. 25, Figure 1, from D to E] This is established within the skull in his proper seat and is compassed or inuested with the membranes: wherefore after the thicke Meninx is remoued, the other called *Pia mater* is also to be taken away, which is transparant and strong, and by whose mediation the forepart of the marrow is tyed to the braine and the hind part to the After-braine. It also detayneth or establisheth the *Spinall Marrow* that it be not reflected backward, which haply is the cause why Anatomists haue not knowne his true originall; for if you take it vp with a hooke and lightly remouue it with a knife from the parts vnder it, and bend the spinall marrow somewhat forward [tab. 25, fig. 2, ab] then will his originall shew it selfe to be not in the *Occipitium* or where it was first tyed to that thin membrane, but ascending somewhat vppward and in the forepart of the braine.

The admini-
stration of the
spinal marrow

This Marrow therefore consisteth of foure roots, whereof the two greater [tab. 25, fig. 2, bc, sheweth the trunk reflected, Charact. 4. and 1. shew the trunk in his owne seate] do issue out of two parts of the braine in the place wherein the ventricles are reflected [tab. 25, fig. 2, fg] from the forward prominence or swelling of the braine vnto the middle, and whereabout the Opticke nerue [tab. 25, fig. 2, cd] passeth without the ventricle.

The 4. roots
thereof.

The other two roots are two short trunks of the *Cerebellum* [tab. 25, fig. 2, Charac. 6.] arising

Where ioined
on

on either side out of the vpper part thereof, which are ioyned to the two greater productions of the Braine euen now spoken of, [tab. 25, fig. 2, betwixt the two Characters 2, and 3,] and so of 4, are made 2, [tab. 25, fig. 1, E] which afterward do accomplish the spinall Marrow, from which all the nerues of the whole body haue their originall as diligent inspection doth sufficiently prooue.

Galen acknow-
ledgeth the
truth of this.

And the same Galen affirmeth in the 13. chap. of his 8. Book *de vsu partium* and in many other places where he saith, That all the nerues which are attributed to the spinall marrow do arise from the After-braine, so that according to his Anatomy the spinall marrow is ioyned to the *Cerebellum*.

He is taxed by
Columbus.
Redeemed by
Varolius.

Some there are (and Columbus among the rest) who heerein taxe Galen, affirming that no nerue proceedeth from the *Cerebellum*. But, saith Varolius, Galens opinion may be after some sort maintained to be true; but those that find fault with him affirme that which is absolutely false, because the spinall marrow ariseth out of 2. roots of the brain whence 2. paires of sinews are produced, and out of 2. roots of the after-braine which are ioyned to the former and do together fulfill or accomplish the spinall marrow; and so all the nerues of the spinall marrow do arise out of the *Cerebellum*.

Why the ori-
ginalls of the
sinews grow
into one.

And verily that this should bee thus, it was profitable yea necessary; for the principles or originalls of all things had neede to be firme and stable. Now by how much any thing is more single and simple, by so much without doubt it is more solid and firme; wherefore it behooued that the originall of all the sinews should be but one simple and single originall. For if all the Arteries and Veines be reduced to one originall, the Arteries to the Heart, the Veines to the Liuer; it is agreeable to the wisdom of Nature that the Nerues also should proceede from one originall; because these are 3. common Organs or Instruments of the body through which the Animall, Vital and Naturall Faculties are by the helpe of spirits transported together with the Vitall and Naturall blood. And this both Hippocrates and Plato seeme to haue knowne. Hippocrates who in the beginning of his Booke *de Natura Osim* writeth, that the Originall of the Sinews is from the *Occipitium* which is the seate of the After-braine. And Plato in *Timaeo* speaking of all the Sinews writeth, That God disposed the Nerues about the lower part of the Head, and compassed them with a spinall Marrow, which is of a substance like vnto theirs.

Hippocrates
and Plato in-
nuate so much.

Why the spinall
marrow ariseth
out of the cen-
ter of the
braine.

Now the Originall of the Spinall Marrow was to be out of the middle part of the Braine, [table 25, figure 2, b c, and Character 4. do manifestly shew it] because through it as it were through a common water-course the spirits which are perfected in the midst of the Braine were to bee deriued into other Riuerets and so into the whole body. Wherefore their beginning was to bee placed in the center of the Braine, neere the Store-house or shop of the Spirits, whence they might receiue them as it were with a full streame; like as Anatomy teacheth vs, that the Arteries and the Veines do arise out of the middle of the Heart and the Liuer.

Obiection.

It will be objected, that this Trunke which heere we call the Spinall Marrow ought not to haue that denomination till it haue attained into the *Vertebra* or racke-bones of the Chinc, and therefore it is improperly sayd that the Opticke Nerues doe arise from the Spinall Marrow. Wee answere, that we haue before sufficiently satisfied this doubt in the 15. chapter of this Booke, yet for further contentment (if they will be contented with reason) we answere by instance; doe not the nerues of the Sight, Hearing and of the rest of the senses receiue their names from the Organes to which they are destinated before they touch those Organes? yea whilst they remaine within the scull? So also this Marrow may bee called the Marrow of the Backe, or the Spinall Marrow before it enter into the Spine. For whilst it remaineth within the Scull it is diuided from the Braine, and in it may be obserued proper Fibres belonging to it selfe alone.

Answered by
instance.

Of the After-braine or Cerebellum.

After we haue done with the spinall Marrow we must come vnto the *Cerebellum* [tab. 25, fig. 1, BB, fig. 2, Char. 8, 9, 10,] bared from the Membranes, which beside two processes called *Vermiformes* which are parts of the substance thereof, and beside the two lateral parts which resemble two bowles closed together, of which we spake sufficiently before in the 14. chapter of this Booke: there remaineth yet another processe thereof to be exhibited and manifested vnto you.

This

Table 25. Figure 1. sheweth the Braine taken out of the Scull separated from the Dura Meninx and inuverted^s whose right side exhibiteth the Originall of the Spinall marrow and the seven Coniugations of the Sinews of the Braine, according to the ordinary received opinion: but the left side sheweth their true originals.

Figure 2. sheweth the Braine inuverted, and the parts thereof in the Basis distracted, as also the Originall of the Spinall Marrow out of the Braine and the After-braine, the largeness of the ventricle, and the Originall of the Opticke Nerue out of the Marrow.

TABVLA. XXV.

- AAA**, The Braine.
BBB, The After-braine.
CC, The swellings of the braine commonly cald the *mamillary* pro-
cesses.
D, The beginning of the marrow of the back, as it is commonly be-
lieued.
E, The termination or end thereof in the Scull.
F, The originall of the Organes of smelling according to the vulgar
opinion.
H, The originall of the opticke Nerues, as it is commonly received.
I, The coate into which the Opticke Nerue is inserted.
2, The second paire of sinews.
3, 4, 5, 6, 7, The coniugations of the sinews, whose originall *Vesalius*
himselfe attributteth to the beginning of the Spinall Marrow.
8, A branch of the third coniugation as Anatomists doe beleue:
which passeth forward, but we take it to be the 3. coniugation.
9, A brāch of the 5. coniugation according to *Vesalius*, but we esteem
it to be a coniugation of it selfe, and therefore cal it the 8. paire.
10, 11, 12, 13, The barke or shell of the Braine; for 8, 9, 10, 11, is the
very marrow of the Braine it selfe, and these two are not continu-
all but onely contiguous, or touching one another.
ab, The whole Optick nerue, and at *b*, is the reflection of the nerue to
the backpart of the Spinall Marrow.
c, The coition or concourse of the Optick Nerues.
de, A part of the 2. nerue not comonly known, whose original is at *e*.
f, g, h, The Marrow of the Braine lengthened and determining in the
Spinall Marrow.
k, The transuerse proceffe of the After-braine which is called the
Bridge.
ll, The auditory Nerue arising out of this proceffe.
lm, The passage of the Organ of smelling lurking betweene the vp-
per and middle prominence of the Braine, & at *l*, is his originall.
n, The middle prominence of the Braine diuided from the rest of the
Braine.
o, The beginning of the backward prominence of the braine from
whence the middle was dissected.
p, The intercussation which the Optick Nerue maketh with the nerue
that moueth the eye.

The Second Figure.

- 1, 2, 3**, The halfe of the Spinall marrow drawne to one side,
4, 5, The coniunction of the same marrow with the ventricle. **6**, A portion of the Spinall marrow growing out of the Af-
ter-braine. **7**, The Optick Nerue reflected in the backpart of the spiaall marrow and entering into the cavity of the ven-
tricle. **8, 9, 10**, The left side of the After-braine from which the right side is remooued. **11, 12**, A slit going vnto the 2. ven-
tricle, which slit is formed partly by the body of the Arch, partly from the inner part of the spinall marrow. **13, 14**, The
coniunction of the right and the left sides of the braine by the Callous body. **a**, The right part of the Spinall marrow refle-
cted vpward to his owne side, that so the originall thereof which is in the cavity of the ventricle might be perceiued. **bc**,
The beginning of this marrow as it respecteth the hollownesse of the ventricle. **de**, The Optick Nerue reflected about the
roote of the Spinall Marrow. **e**, the first originall of th Optick Nerue. **f, g, h**, the whole cavity of the ventricle, **f** sheweth the
Anterior, **g**, the middle, and **h**, the Posterior cavity hollowed in the Braine. **ik**, the complication of vessels cald *Plexus cha-
roides* about the roote of the spinall marrow in the ventricle. **lm**, A portion of the Basis of the Braine which together with
the spinall marrow maketh the cleft which entreth into the ventricle. **no**, the length of the callous body which ioyned to-
gether the two sides of the braine. **pqr**, Portions of the braine reflected backward that the cavity of the ventricle might
better be perceiued.

This proceffe is a very notable one, [tab. 25, fig. 1, k] arising on either side out of the Cere-
bellum neere the trunks whereof the spinal marrow is amassed, & runneth ouerthwart forward
and downeward, by the mediation whereof this After-braine imbraceth the fore-part of the
Spinall Marrow after the same manner that the transuersall or ouerthwart muscles of the

The proceffe
called the
Bridge.

Larynx,

FIG. I.

FIG. II.

Larynx, making the 3. paire of common muscles doth imbrace the backpart of the beginning of the *oesophagus* or gullet and thence are called *oesophagi*: and this proceſſe is diſtinguiſhed by a courſe of ouerthwart fibres with a kinde of eminency from the right fibres of the Spinal Marrow.

This proceſſe *Varolius* calleth *pontem cerebelli*, the bridge of the After-braine, from the ſimilitude it hath with a bridge, becauſe vnder it the ſpinal marrow runneth as a ſtreame runneth vnder a bridge.

How the auditory nerue ariſeth out of the Bridge.

Two pretty queſtions reſolued.

Galen injured by the *Necroticks*.

Varolius.

At this proceſſe the *nerue of hearing* hangeth and hence ariſeth, [*tab. 25, fig. 1, i*] ſo that we may boldly aſſure that the *Cerebellum* is alſo the firſt originall of the ſenſe of hearing. And this beginning of the auditory nerue teacheth vs the cauſe why more from the infancy are deafe then deſtitute of any other ſenſe; for becauſe they proceed from the After-braine and run no long courſe, they are eaſily filled and choaked with *Mucous* and ſlimy excrements; and this is the reaſon, as ſaith *Cassius* in his 17. Probleme, why children from their infancy looſe their hearing of both eares together, whereas vpon an accidentall diſeaſe it is more vſuall to haue one alone vitiated.

Seeing therefore almoſt halfe of the ſpinal marrow and this proceſſe or bridge from which the auditory nerue ariſeth doe proceede from the After-braine; *Varolius* thinketh that *Galen* hath great wrong to be taxed by the late Writers, when as they affirme againſt him that no nerue hath his originall from the *Cerebellum*: for ſaith he, ſome nerues ariſe only from the brain and not from the After-braine as the optick ſinews; ſome from the After-braine only, and not from the brain as the auditory nerues; ſome from them both together as the nerues of the ſpine: but no nerue ariſeth immediately out of any of the two principles but all out of their owne principles eyther by the mediation of the ſpinal marrow or by the mediation of that tranſuerſe proceſſe which we called the Bridge.

Of the Nerues of the eyes.

The common received originall. The true originall.

Why Cauterics at the necke helpe the eyes.

How to demonſtrate the Opticke nerues.

The moving nerues.

Why both eyes moue together.

Next followeth the nerues of the eyes, and becauſe there are two payre of them, the one called *optici*, the other *motorij*, becauſe they moue the eyes; we will firſt ſpeake of the *opticks*. They ſay they ariſe out of the baſis of the braine but toward the forepart, [*tab. 25, figure 1, i*] whereas indeed a great part of them proceedeth from farther off, [*tab. 25, fig. 1, from p to b*] and lurking in a certaine ſpace formed betwene the braine and the beginning of the ſpinal marrow, they runne out toward the *occiput* where they ariſe [*tab. 25, fig. 2, ſheweth their originall*] out of the beginning of the former trunks of the ſpinal marrow, [*tab. 25, figure 2, b c*] where they reſpect the cavity of the ventricles of the braine, [*tab. 25, fig. 2, g*] and in the backpart thereof they are reflected toward the middeſt. [*tab. 25, fig. 2, d e*] Wherefore ſeeing the originall of theſe nerues is almoſt in the *occipitum*, it followeth (as alſo we finde it true by daily experience) that Cauterics applied to the *Occipitum* are of great vſe in the diſeaſes of the eyes: which out of queſtion hapneth becauſe the originall or beginning of the opticke ſinewes being depurated and confirmed, the viſible ſpirits haue freer recourſe vnto the eyes.

If you would demonſtrate theſe ſinews you muſt remoue the *Pia mater* at that place where the Opticks are commonly ſaide to ariſe; but carefully that you hurt not the nerue, and then you may perceiue that the braine there is onely contiguous; then draw the braine lightly forward from the marrow till you finde the Opticks there lurking, and if you thruſt a probe without violence between them and the parts to which they adheare, you may lift them from the ſubieſted parts till you come to their originall, and withall you ſhall perceiue where the ſpinal marrow taketh his beginning out of the braine. They ſay commonly that the moving nerues [*tab. 25, figure 1, Chara. 2*] haue their beginning nere the Opticks, a little more outward; but if you cut a part of the braine toward the midſt you ſhall perceiue them diſtinguiſhed from the braine to attaine to the middle of the head and to paſſe vnder the Opticks after they haue made an intercuiſſion, [*tab. 25, fig. 1, d*] that is, haue croſſed one the other, and do ariſe at the inner part of the beginning of the ſpinal marrow, [*tab. 25, fig. 1, e*] and in their originall are ſo vnited that they touch one another in one corner, which haply is the cauſe why both the eyes are together moued to the ſame ſide.

That the reſt of the coniugations of the ſinewes of the brain do yſſue from the Spinal marrow, *Vesalius* is content to affirme, excepting onely the third. *Columbus* acknowledgeth that third with all the ſubſequent coniugations to ariſe from the ſaid marrow, and for the two firſt paires we haue euen now proued their originall: it remaineth that we proceed to the inſtruments of ſmelling.

The

The Instruments of Smelling or the Mammillary processes.

The instruments of smelling or the *anterior* processes of the braine which proceed outward betwixt the optick nerues vnto the fissure of the spongy-bone scituated at the top of the nose, are commonly esteemed to arise out of the basis of the braine [tab. 25. fig. 1, F] neere the conjunction of the optick nerues [tab. 25. fig. 1, C] But the truth is, that Anatomists hitherto haue shewed only the one halfe of these instruments; for beside that they doe shew [tab. 25. fig. 1, from m, forward] they proceede as much farther [tab. 25. fig. 1, from m, to l,] lurking betwixt the forward and the middle swelling of the braine; for their progresse is backward, and by how much they reach further, by so much is the distance more betwixt them. They are also by little and little attenuated, growing thin vntil they determine into a sharp point at the sides of the braine almost at the utmost limit thereof [tab. 25. fig. 1, at n] which is about the holes where the aire beateth into the eare, for this is the place of their original. And hence haply it is that if the smelling be intercepted, the hearing also is somewhat affected; for we see that when vpon a cold or murre (as we call it) the nose is stopped and the smell hindered, the hearing also is somewhat offended: we also manifestly perceiue that when we sneeze or blow our nose or retaine our breath by shutting vp our nostrils, the hearing is also instantly interrupted, and those that loose their smell doe very easily become deafe: it may also be that from this sympathy that Probleme of Aristotle the 5. of the 11. Section, and the 23. of Cassius, Why those that be deafe do speake through the nose may be alloyed.

Their common receiued originall.

Their true originall.

Of the sympathy between hearing and smelling.

Of the Ventricles of the Braine.

These things being thus demonstrated, and the eyes with the optick nerues being drawn each into their own side, you must lengthwise cut into 2. parts the bridge of the *Cerebellum* and the spinall marrow, then must you remoue the *Cerebellum* quite away, and one part of the spinall marrow so denided lengthwise as we said before must be drawne to his own side, and one side of the braine both before and behind must be cut to shew the magnitude and figure of the ventricles thereof, for this Administration sheweth a great difference in the scite, magnitude, forme, number and vse of them from the common demonstration.

How we must proceed in this kind of section.

The receiued opinion is that there are 4. ventricles, *Arantius* in his obseruations accounteth six, 4. acknowledged by the ancients and vnder these 2. other; but indeed and truth by how much the number is increased, by so much is the error the greater, there being in truth but 2. for the braine both of man and beasts being double, as 1. *Hippocrates* obserued in his Book of the *Falling sicknes*, and after him *Aristotle* in the 10. chap. of his 4. Book de *Historia animalium*, it seemeth equall that each part should haue a ventricle. For those 2. which they place in the forepart of the braine are as well seated in the middle and in the hind-part as they are before: for hitherto scarce their 4. part hath beene demonstrated, their magnitude being answerable and proportionable in respect of their forme to the magnitude of the whole braine, and the swelling prominences thereof: neither is it to be doubted but that the cauities of the braine while the creature is alieue are farre larger then after he is dead, because after death the braine that was stretched and as it were extended with spirits, when those spirits are vanished falleth into it selfe and so the cauities are lessened and contracted.

Hippocrates Aristotle.

The magnitude of the ventricles.

Now the brain is on either side long, and where the 2. sides the right and the left do regard each other it is plaine and depressed, in other parts it hath sphericall or round productions or prominencies answerable to the hollownes of the bones wherein it is contained.

The *anterior* or forward prominence filleth the cavity formed by the forehead bone, a part of the spongy bone, the bone of the *sinus* or side of the head, and the wedge-bone, the middle and lower prominence filleth on both sides the cavity formed by the backpart of the wedge-bone, the forepart of the stony-bone and the bone of the temples.

The anterior prominence.

The *posterior* or backward prominency filleth the cavity made by the vpper part of the *occipitum* and the latter part of the wedge and stony-bones. And to these prominences the cavity of the ventricles is answerable; for from the forward prominences there runneth a notableosome or hollownes, euen vnto the latter or backward; which *Sinus* or hollownesse is so farre distant from the out side of the braine in the backpart as it is in the forepart.

The posterior.

But when it attaineth vnto the angle or corner which is in the vpper part of the stony-bone, it is reflected to the middle and lower prominence of the braine, and after the same manner

is excavated or hollowed in that prominence or production as it is in the *Anterior* or *Posterior* parts.

But why is the ventricle thus figured? why did Nature neglect the round figure and reflect it thus into it selfe? *Mercurialis* maketh answer; That as in a pond or Lake wherein water may rage, men do frame out some oblique angles, or corners wherein his direct & impetuous course might be broken: or as it was in that Haven into which *Æneas* put in a storme, against the sides whereof *Virgil* saith:

omnis ab alto

Frangitur, in-que sinus scindit sese unda reductos.

The waues are broken from the Mayne,

And in the Creekes are cut in twaine:

So Nature to interrupt the violent motion of the spirits, least they should offend the wals as it were the shores of the ventricle, cut out these angles or set out these Peeres against which or in which their violence might be broken.

Furthermore the braine, which without the compasse of the ventricles is very thicke (considering the ventricles as they are commonly demonstrated;) if you haue a respect to these two ventricles as we exhibite them, is farre thinner then it is in others parts, & like a shell compasseth these 2. cavities, which truly might be called but one ventricle were it not distinguished by the interposition of that body which is called *Corpus callosum*; [tab. 25. fig. 2. mmo] and these only are the ventricles of the braine. Now what those parts are which are commonly called the 3. and the 4. ventricles it remaineth that we shew vnto you.

What are the
3. and 4. ven-
tricles com-
monly so cal-
led.

The whole braine as also the spinall marrow is diuided into two parts, and is only ioined in the middle and lower part by that Callous body we spake of euen now, [tab. 25. fig. 2. mmo] which is nothing else but the braine in that part conioyned. For where the right and the left parts were to be ioined they are bent a little outward, afterward growing white they are reflected to the middest and so vnited. This vnion hath a kinde of conuexity or embowed figure proportioned to the conuexity of the brain, which also is as long as the sagital suture or seame. Some think that it is harder then the other parts, but we thinke it is as soft as the braine it selfe, and is very white like the inward parts or sides of the ventricles. The interior part of this vnion is ordinarily called *Fornix* or the Arch.

The *Corpus*
Callosum.

The Arch of
the Braine.

The 2. Trunkes produced from the braine being become round do touch one another, and so bend somewhat forward; but againe returne backward toward the hole of the *Occipitium*; and because they are round bodies they make betwixt themselves in their first contaction a light angular or cornered cauity vpon which the Basis of the braine being vnited doth leane it selfe, so that from the mutuall touch of the bodies before spoken of, that space is formed which they call the 3. ventricle, which to say truth is without the braine and formed not by any intention of Nature but of necessity, because of the coniunction of these bodies.

The third
ventricle.

In the vpper part hereof towards the sides there appeare 2. long slits or fissures which run almost through the middle circumference of the trunkes of the spinall marrow, and so passe into the ventricles of the braine, and by the way of these fissures the ventricles haue an outlet vnto that they call the 3. ventricle. And because the foresaid trunkes do reach as farre as to the Saddle of the Wedge-bone where the Tunnell is, therefore it is commonly said that the *Anterior* passage of the 3. ventricle reacheth vnto that part.

The fourth
ventricle.

The 4. ventricle so called, is a *Sinus* or hollownes betwixt the lower part of the *Cerebellum* & the vpper trunkes of the spinall marrow, where the same spinall marrow is caued or hollowed like a writing pen. This *Sinus* or bosome is made of the 2. trunkes proceeding out of the *Cerebellum* for the framing of the spinall marrow, & is lengthened out of the distance of both those propagations of the After-braine. For before they bee vnited with those two other greater trunkes which arise from the braine it selfe, they passe along about them a litle distant one from the other. So that this cauity like as the other, ariseth rather vpon necessity of the position of the parts then from any foresight or intention of Nature; because like as the third so also this fourth ventricle is situated without the braine and the *Cerebellum*.

The funda-
ment of the
Braine.

That hole which is called the latter *foramen* of the 3. ventricle, which some make to be like vnto the fundament and will haue to enter into the 4. ventricle; is nothing else but a space made by the contaction or mutuall touching of the 4. trunkes of the spinall marrow where the trunkes of the *Cerebellum* are bent downeward and adheare or cleaue to the Trunkes arising from the braine.

The buttocks
and Testicles.

Here appeare foure orbicular prominences commonly called the Buttocks and the Testicles of

of the braine, which they commonly affirme to be within the braine though indeed they are without. And these *Varolius* thinketh to be the true originals of the spinall marrow: and that the buttocks are nothing else but portions of the roots of the spinall marrow proceeding out of the *Cerebellum*, like as the Testicles are small portions of the roots proceeding from the Braine.

The buttocks
and Testicles.
The true ori-
ginals of the
spinall marrow
after *Varolius*.

Concerning the vse of the ventricles, the common opinion is, that they are the receptacles or receptacles of the Animall spirits as the left ventricle of the heart is the place of the vitall spirit. But although we wil not deny that there may be many vses assigned to one and the same part: (and therefore *Galen* in the 10. Chapter of his 8. Booke *de Usu partium*, was of opinion that the vpper ventricles did serue for the preparation of the spirits and also for the expurgation of superfluities,) yet we are of opinion that these ventricles are the receptacles of the phlegmatick humor which is ingendered in the braine, which through the *infundibulum* or Tunnell is conuayed to the phlegmatick glandule and so purged away. For the ventricles haue no where any outlet but only at the Tunnell: but for the Animall spirits we thinke that they are disseminated through the whole substance both of the Braine and of the After-brain. And this we shew first by the testimony of *Hippocrates*, who when he had deliuered that man consisted of 4. humors, and did assigne to euery one their proper place he saith; That the place of the spirits and of the blood is in the heart, of yellow choler in the Liuer, of blacke in the spleene. And if the place of phlegme be in the braine there must of necessity be a cavity which may containe it; such as is the ventricle in the heart and the bladder of gall in the Liuer. Now beside these two ventricles there is in the braine no cavity at all.

The vse of the
Ventricles.

Galen.

That the ven-
tricles receiue
the phlegme.

Hippocrates
his 1. reason.

Secondly, it is proued by the generall vse of Glandules which is to sucke vp and consume superfluous humidity. Whereas therefore in these ventricles there are Glandules found in that complication or web of vessels therein disposed; it followeth that phlegme is therein gathered, which distilleth out of that texture or web into the ventricles and there is heaped together; (for they are not able to consume so great a quantity) otherwise both the glandules should be in vaine added by nature, and their vse and commodity assigned by *Hippocrates* should be idle and of no vse.

2. Reason.

Furthermore it is acknowledged by all men that the phlegme doth distill from the braine through the Tunnell vnto the Pallat. Now the beginning of the Tunnell is in the ventricle, neyther is there any passage from any part of the braine vnto the Tunnell vntlesse it be out of the said ventricles.

3. Reason.

Fourthly, it is proued by an argument taken from necessity: because this phlegmaticke excrement did require great and large cavities. For if there had beene no conuenient place wherein a notable quantity thereof might bee stabled or heaped together; wee should haue beene troubled with continuall spitting and spawling (euen as they in whose bladders the vrine is not collected and retained doe continually awoyd their water by drifling or drops) and so our speech and other noble actions interrupted. And hence it is that in sleep a great quantity of this phlegme being collected, after we awake we auoide it plentifully in a short time. Now this quantity because it could not be contained within the *Dennes* or hollow cavities of the nose behooued to haue some other receptacle in the braine wherein it might bee reserved till convenient time of euacuation.

4. Reason.

Many instan-
ces from our
sence.

We do also sensibly perceiue that if a man be desirous to spit and therefore suck the vpper part of his Pallate; he shall gather great quantity of this phlegmaticke excrement into the cavity of his mouth and thence spit it forth. But if he againe instantly strue to spit he shal auoid a lesse quantity; and so lesse and lesse till by sucking he can gather no more spittle. But after a short interim or interposition of time the excrement will againe fall into his mouth; which is a most euident signe that this matter is in some notable quantity collected or gathered together before it be auoyded as it is in the vrine and the excrements of the belly.

What we con-
clude.

Wee conclude therefore that these cavities of the ventricles do receiue the foresaid excrements, because those glandulous complications doe enter into them; and out of them only are the passages by which the moysture is auoided.

Mercurialis opposeth on this manner. How may it be that so thicke, cold and obscure or dull a humour so contrary to the Spirits should bee collected in that place where the Spirits themselves which are pure and subtile bodies are as it were in an Ouen baked and perfected? Moreover, the causes of an Apoplexie, Epilepsie or Falling sicknesse, and the *Incubus* or Night-Mare, are by all Physicians acknowledged to bee, when as Flegme or Melancholie, or Crasse and thicke winde is retained in the Ventricles, which stopping them vp cyther wholly

Mercurialis
his obiections.

Hippocrates

wholy or for the most part, do strangle the spirits therein contained, which (as *Galen* saith in his 3. Book *de Locis affectis*) *Hippocrates* signified in darke and obscure words in the end of the second Section of the first Booke *Epidemion*, where he writeth, *That the disease called Melancholia hapneth when the humour falleth into the seate of the minde, and the Epilepsy when it falleth into the body of the braine.*

Plato.

Plato also consenteth with *Hippocrates* in *Timaeo* where he writeth, that the falling sicknesse happeneth when Flegme mingled with Melancholy catreth into the diuine caviities of the braine. *Varolius* maketh answer on this manner. For the causes of the Apoplexy, Epilepsy, and *Incubus*, although I sometimes read in *Hippocrates* as in the 9. Text of his Booke *de Glandulis*, that the Apoplexy is occasioned by the *Corrosion* of the braine, and in the 19. and 20. Text of his Booke *de Flatibus*, that the Epilepsy is caused when the blood is disquieted and defiled in all the veines, as also when the same veines are obstructed. And that I read in *Galen* in the 7. Chapter of his 3. Book *de Locis affectis*, that he doubted whether the Epilepsy were made by an obstruction of the ventricles of the Braine, of the Spinal Marrow, and therefore that I willingly graunt that these diseases may haue these causes: yet I conceiue that it will not abhorre from reason to thinke that the ventricles (though the Animall spirits be contained in them) are sometimes so fulfilled with a viscid humor or thicke wind, that the first root of the Spinal marrow may be compressed by the aboundance thereof, so that the transportation & affluence of the spirits thereunto may be interrupted and intercepted, and consequently the whole body deprived of Sense and Motion. Like as the Bladder in the suppression of the Vrine being beyond measure distended lying hard vpon the guts, the auoyding of the excrements is hindered.

Varolius his
Answer to
Mercurialis.The causes of
the Apoplexie.
Hippocrates.
Galen.Do not con-
tradict *Varo-
lius* opinion.Another satis-
faction.This opinion.
Confirmed
by Dissection.

And if this answer will not please the Pallate, I will say with *Galen* in the place before quoted, that the Epilepsy and such like diseases do proceede by the obstructing or immuring of the Spirits, which happeneth when the beginning of the Spinal Marrow is choaked by an vnnaturall confluence of humours vnto it. And this opinion is confirmed by the Dissection of the Heads of such men as dye Apoplecticall, in the Ventricles of whose brains there is not found any greater quantity of excrements then is commonly found in other men.

Another
Obiection.
Answered.

Furthermore, they Obiect that in the Epilepsie, the Apoplexy and the *Incubus*, the Animal spirits residing in the Ventricles of the Braine are strangled or their out-gate hindered. *Varolius* answeres that these diseases happen not from any humour or winde atteyning any way vnto the Ventricles, but by reason of a great quantity and notable thicknesse, or sudden eruption. Wherefore euen as the excrements descending by the Pallate and the Nose do not offend the taste or the smell if they passe through those Organs moderately and according to Nature, but do either hinder or vterly intercept their Operations if they exceede the Measure and Proportion of Nature in quantity or in quality: so wee thinke wee are to conceiue of the excrements accruing vnto the Ventricles of the braine or receding therefrom.

That the spi-
rits are in the
substance of
the braine.
Galen.

Now that the Spirits are dispersed through the substance of the braine, wee prooue by the testimonie of *Galen* in the 13. Chapter of his eighth Booke *De Vsupartium* where hee sayth, That the Animall spirit is in great quantity conteyned in the body of the braine, as also of the *Cerebellum* to which hee attributeth the Originall or beginning of the Nerves of the whole body, and therefore he inferreth that it is necessary it should be filled with the aboundance of spirits.

The conclu-
sion.

If therefore the *Cerebellum* which hath in it no cavity at all doth yet conteyne in his substance plenty of spirits which flow from it to so many nerves removed by so great distances therfrom, why may we not beleuee that after the same manner yea a great dealc rather the spirits may be conuayed without manifest caviities out of the braine to a fewer nerves and those not far distant from it but euen at hand? Seeing therefore that the Animall spirits can ebbe and flow without any sensible passage, why may wee not ascribe that vnto the substance of the braine which others haue ascribed vnto the Ventricles because they haue not duely obserued them?

Of the web or complication called Plexus Choroides.

Of the Plexus
Choroides.

Finally, the complication or web of vessels which they call *Choroides* or the Net which is in the Ventricles of the braine [tab. 25, fig. 2, ik] seemeth to be altogether glandulous or kernelly

nelly, so that both in substance and colour it may be likened to the Pine-glandule we spake of in the 12. Chapter; yet if you handle it nicely and mark it diligently, you shall find that it is nothing else but a heape of broade and long membranes growing out of the *Pia mater* of the braine, at the one side whereof through out their whole length hangeth a little thicke vessell full of excrementitious moysture, through which exceeding small vessels are deriued: and if wee compare little things with great, it is like a gut tyed vnto the mesentery, yet for the proportion of it, there are more glandules then in the mesentery of the lower belly. And this manifestlie appeareth in their heads whose braines are very moyst and therefore saith *Varolius*, it were more agreeable to their nature to cal them glandulous then *Net-like complications*.

What it is.

And if any man doubt whether the substance of them be such as we haue said, we remit him vnto his owne ocular inspection, there being no argument of greater validity. For saith *Varolius* in all carkasses which we haue opened, we haue found these glandules ful of such a muddy moysture as we finde in the rest of the glandules of the body. Albeit *Archangelus* doe thinke that such excrements are onely found in diseased braines.

That it is glandulous.

The vse of this glandulous complication seemeth to be; that like other glandules it might sucke vp the superfluous moysture of the braine, for that is the office of the glandules in the whole body: yea *Hippocrates* himselve in the second Text of his Book *de glandulis*, proueth by an induction of the particular glandules of the whole body, that when the body aboundeth with superfluous humidity it is thereof exonerated and discharged by the glandules; yea hee proceedeth so far as to say that the whole substance of the braine is glandulous.

The vse of this complication.

Now concerning the rest of the parts of the braine of which in this new demonstration or dissection we haue made no mention, you must conceiue of them as their histories are described before.

But if a man be desirous in this kinde of Section to demonstrate or exhibite to the spectators all the parts, then must he proceede in this order. After he had taken away all the bones of the head by sawing them through the length aboue and beneath, before and behind, he must first make demonstration of the *Sinus* or vessels of the *dura meninx*. Afterward turne the head and at the Basis of the braine separate the *Meninx* from the spinall marrow, yet must he leaue portions of the *Meninx* about the nerves that they be not broken, for then you cannot follow them to their originall.

How this must be accomplished.

Vnder the membrane which inuesteth the spinall marrow there appeareth a texture or web of vessels diuersly crossing one another, which they commonly call *Rete mirabile*, the Wonderfull Net; then the flegmatick glandule commeth in sight which is almost square, and the neck of the Tunnel which are scituated without the thick *meninx*. From hence our eye passeth vnto the membrane of the spinall marrow and the marrow it selfe; which being lifted vp we behold the buttockes, the testicles, the passage into the fourth ventricle and the fourth

How the particular parts of the brain arise.

ventricle it selfe, all which are without the braine. Wee see also the After-braine, the processes thereof, the Auditory Nerue, the mouing Nerves of the Eye together with the Opticks, the Organs of smelling, the two ventricles of the braine together with their passage into the Tunnell, as also the Callous body, the Arch, the Complication called *Choro-*

roides, and the Pine-glandule. And thus much

concerning *Varolius* his new way of disse-

cting the head, which we haue added

as an accomplishment to this

Book of the braine, because in-

deed after this manner all

the parts thereof are

best shoune and

to best purpose.

Now we pro-

ceed to the

Contro-

uersies.

A Dilucidation or Exposition of the Controuersies concerning the Braine and the Parts thereof.

QUEST. I.

Whether the Braine be the Seate of the Principall Faculties.

A division of
the Animall
Faculties.
The common
sense.

THe Animall Faculties are by the Physitians distinguished into Faculties of *Sense*, Faculties of *Motion*, and *Principall* Faculties. The sensitive Faculty is double, one Externall whose object is Singular or one; the other Internall whose object is common or manifold: this Internall Faculty, the Philosophers call the *Primarie* or *Common sense*; and this is it which alone maketh the differences of *Images* as we call them or *Abstracted Notions*. She sitteth in the substance of the Braine as in a throne of Maiesty beholding the *Formes* or *Ideas* of all things vnder her feet. This is she that discerneth betwixt sweete and bitter, and distinguisheth white for sweete. This common sense *Aristotle* compareth to the center of a circle, because the shapes and formes received by the outward senses are referred or brought hereunto as vnto their Iudge and Censor.

The Imagina-
tion.

After this inward sensitive Faculty do follow the principall Faculties, and first of all the *Imagination* which conceiueth, apprehendeth and retaineth the same *Images* or representations which the *Common sense* receiued; but now more pure and free from all contagion of the matter, so that though those things that moue the senses be taken away or otherwise doe vanish, yet their footsteps and expresse Characters might remaine with vs. And this conception or apprehension we call *Phansie*. By this *Phansie* that supreme and soueraigne *Intellectuall* power of the Soule is stirred vp and awaked to the contemplation of the *Ideas* or *Notions* of vniuersall things.

The Intelli-
gence.

The memory.

Finally, all these are receiued by the *Memory*, which as a faithfull recorder or Master of the Rolles doth preserve, store vp and dispose in due order all the forenamed *Notions* or abstracted formes. And these are the principal faculties according to the Philosophers and the Physitians, concerning which we haue three things to enquire.

3 Questions.

The first, whether the Braine be the seate of them all. Secondly, whether in the Braine these diuers faculties haue diuers Mansions. And lastly, whether these principall faculties do result or arise out of the temperament or from the conformation of the Braine, that is, whether they be *Similar* or *Organicall* actions.

Diuers opini-
ons.
Herophilus.
Xenocrates.
Erasistratus.
Empedocles.
Moschion.
Blemor.

Concerning the seate of the Reasonable Soule, the opinions of the Philosophers and Physitians are verie different. *Herophilus* placeth it about the Basis of the Brayne. *Xenocrates* in the top of the Head. *Erasistratus* in the Membranes of the Braine. *Empedocles*, the *Epicures* and the *Egyptians* in the Chest. *Moschion* in the whole Body. *Heraclitus* in the outward motion. *Herodotus* in the Eares. *Blemor* the Arabian in the Eyes, because the Eyes are the discoverers of the Minde, and so fitted and composed to all the affections and affects of the same, that they seeme to be another Soule, for when we kisse the Eye we thinke we touch the soule it selfe.

Strato Phys-
icus.

Prouerbe.

Strato the Naturalist thought the Soule inhabited in the Eye-browes, because they are the seate of *Pride* and *Disdaine*, and therefore the Poets were wont to call *Pride* the Eye-brow, and we commonly say of an insolent man, that we see pride sitting vpon his browe. Moreouer from the haire of the browes the Physiognomers gather signes of the disposition of the Minde

minde. For if they bee straight it is a signe of a soft and flexible disposition; if they bee inflected neere the nose they are a signe of a scurrulous Buffon; if they bee inflected neere the temples they argue a scoffing Parasite; if they bend all downewards they are an argument of an envious inclination. The *Peripateticks* and *Stoicks* doe all of them place the faculties of sense and vnderstanding in the heart, because say they that that is the principle or beginning of motion, is also the originall of sense: But the heart is the principle of all motion, because it is the hottest of all the bowels and a liuing fountaine of Naturall heate. Moreover, in passions of the minde, as Agonies, Feares, Faintings and such like, the Spirits and the Heate returne vnto the Heart as vnto their Prince. And for this they bring the authority of diuine *Hippocrates* in his golden Booke of the Heart, where hee saith, *The Soule of a man is seated in the left ventricle of the heart, and from thence commandeth the rest of the faculties of the Soule, and it is nourished neither with meate nor drinke from the belly, but with a bright and pure substance segregated from the blood.*

Strato his Thy
slogomy of
the eye-brows.

The opinion
of the *Peripa-
teticks*.

Hip. authority.

We with *Hippocrates*, *Plato*, *Galen* and Physicians, do determine. That the braine is the seate of all Animall faculties, for if the braine be offended, wounded, refrigerated, inflamed, compressed, or after any other manner affected, as it is in a Phrensie, *Melancholia*, *Caros*, *Catoche*, or *Epilepsie*, we may discern a manifest impeachment of all the Animall functions, which if we desire to cure, wee apply our remedies not to the heart but to the braine. But if the heart were the seat of the principall faculties then in all affections or notable distemper thereof, all the functions should bee interrupted, because the action is from the Temperament. But in a *Hecticke* Feuer in which there is an vtter alienation of the Temperament, the voluntary and principall faculties remaine sound and vntainted. When the heart is violently moued as in Palpitation, neither is the voluntary motion of the parts depraued nor reason it selfe. Who will deny that the vitall faculty is oppugned by a pestilent aire, the byting of a venomous creature, or by taking of poyson: but all those that are so affected do yet enioy their sense and reason. If (saith *Galen* in his 2. Booke *de placitis Hippocratis & Plat.*) you bare the heart and presse it, you shall perceiue that the creature will not be hindred in his voice, his breathing or any other voluntary action.

The opinion
of the Physi-
cians.

That the brain
is the seat of
the Animall
faculties.

And whereas *Hippocrates* placeth the Soule in the heart, haply he speaketh after the manner of the common people as he vseth oftentimes to doe; now the vulgar imagined that the soule was in the heart. So he calleth the *Diaphragma* or Midriffe *opis* the Minde, when as notwithstanding those Vmbles haue no power whereby the creature doth vnderstand any thing, as he teacheth in his Booke *de morbo Sacro* or the Falling sicknes.

Hippocrates
Expounded.

Or we say that by the soule in that place he vnderstandeth the chiefe instrument of the soule, to wit, the Heate. So in his 1. Booke *de Dieta* he commonly vseth the word Soule for Heat, as when hee saith *That the Soule of man is encreased euen vnto his death.* And againe in the same Booke *The Soule creepeth into a man being mingled of fire and water.* Where by the Soule I vnderstand the heat throughly dewed or moystned with the in-bred and primigeny moysture and the spirits. And that in his Booke *de Corde* by the Soule he vnderstandeth the heart, those words doe declare, where he saith, that the Soule is nourished by the most pure and defecated blood. Now in his first Booke *de Dieta*, he writeth that the Soule cannot be altered neither by meates nor drinks. Which place because it is as bright as the Sun in his strength and worthy to bee written in golden Letters, we wil here transcribe. *The causes of all those things whereby the Soule is altered, are to be referred to the Nature of the passages through which it penetrateth. For as the vessels are affected whereinto it retyleth and to which it falleth and with which it is mixed, such is their condition; and therefore we cannot alter them by dyet, for it is impossible to alter or change the innisible Nature.*

Hip. oftenseth
the word soule
for heate.

An elegant
place of *Hip.*
concerning
the immorta-
lity of the
soule.

In his Booke *de morbo Sacro*, he affirmeth, that in the heart there is no wisedome or intelligence, all saith he is in the power of the Braine. From the Braine we vnderstand, doate and grow mad, as it is hotter, or dryer, or colder.

Galen in his 3. Booke *de Placitis Hip. & Plat.* conuinceth by many arguments that the brain is the seate of all the Animall faculties. And in the fourth Chapter of his third Booke *de locis affectis* according to the opinion of the vulgar he accounteth that man foolish that wanteth braines. For the further confirmation of this opinion we will adde an elegant argument of *Philo.*

Galen.

Wherefoener the Kings Guard is there is the person of the King whom they doe Guard; but the garde of the Soule, that is, all the organs and instruments of the Sences are placed in the head as it were in a Citadell or Sconce; there therefore doth the Soule keepe her Court,

Philo his argu-
ment.

there is her residence or Estate. If therefore the sensatiue faculty be placed in the Braine, the Intellectuall must be there also, because as saith the Philosopher the office of the Intellectuall faculty is to behold and contemplate the Phantasmes or Images which by the Senses are represented vnto it. We resolute and conclude therefore that the braine is the seate of all the Animall faculties as well Sensatiue as Principall.

QUEST. II.

Whether the Principall faculties haue distinct places in the Braine.

What a principal faculty is.

The opinion of the Arab. that they haue distinct seates.

The first argument.

The second.

The third.

Histories

Being therefore the Principall faculties are there: Imagination, Reason and Memory; and that their seate or habitation is resolute to be the braine: let vs now enquire whether they haue distinct & particular mansions provided for euery one of them. *Galen* in his Book *de Arte parua* defineth principall functions to be such as issue onely from a principle: and in the 2. *de locis affectis* he addeth. Which are accomplished by no other part as by an Organ and Instrument. And yet more plainly in the 7. Book *de placitis Hip. & Plat.* Which are only in the braine and thence doe proceed, not receiuing their operation from any other Organs of sense or motion.

The whole Schoole of the *Arabians* hath imagined certaine mansions in the braine, and assigneth to euery particular faculty a particular seate; & this is *Auicenna* his opinion, *Fen. 1. primi, doctrina, 6. Cap. 5.* As also *Auerroes* in his Canticles, his Book *de memoria & reminiscencia* and in *Colliget.*

They place therefore the Phantasie in the forward ventricles, Reason in the middle, and Memory in the hinder ventricle: and this opinion may be established by many arguments on this manner. Almost all the senses are placed in the forepart of the head, wherefore because the Imagination is to receiue and apprehend the species and representations of sensible things it must be placed in the forepart.

By the Imagination the Intellectuall power is stirred vp and abstracteth the Images of things from those Imaginations, and therefore it must bee situated next vnto the Phantasie; and because that is the most immediate Instrument of the reasonable Soule, it was fitte it should reside in the safest and most honourable place which is the middest, that is, the third ventricle.

This Intellectuall faculty commendeth those abstracted formes of things vnto the Memory, which it layeth vp as it were in a Treasury, and therefore the seate of the Memory must be in the hindmost and driest part of the braine which is the fourth ventricle.

Againe, the Imagination being a conception of Images, and accomplished onely by reception and simple apprehension, requireth the softer substance of the Braine wherein such sensation might be made. The Memory desireth the harder substance of the Braine that it might be able the longer to retaine those Notions which it storeth vp. Ratiotination is best pleased with a substance of a middle nature betwixt the softer and the harder. Now the forepart of the braine is the softer, the hinder part the harder, and the middest of a middle constitution; & therefore the Imagination is in the forward ventricles, Ratiotination in the middle, and Memory in the hindmost.

Thirdly, that these principall faculties are disclused or separated by their mansions these things doe demonstrate; because if one of them be offended yea or perish vterly, yet the other may remaine vntainted or vnaffected. For it oftentimes happens that the Imagination is viated & yet the Intellectuall faculty not at all deprauid. For the confirmation of this we haue many elegant Histories in *Galen*, as in the 3. chap. of his Book *de Symptomatum differentiis* and the 2. chap. of his 4. Book *de locis affectis*. *Theophylus* being otherwise able to discourse very well, had yet an Imagination that there were Fiddlers in the corner of his Chamber and continually cried to haue them thrust out. Another being Phreneticall lockt the doores of his Chamber to him and carried all the vessels to the Windows, where giuing euery vessell his proper name he asked those that passed by, whether they would command him to cast them out. *Thucydides* reporteth that when the plague was so hot throughout all *Gracia* and *Peloponnesus* that many which recovered did so vterly forget what they had known before, that they did not remember their Parents or familiar friends. In these men therefore only the Memory was offended; in *Theophylus* onely the Imagination, and in him that was Phreneticall onely the Intellectuall faculty or vnderstanding.

More-

Moreover, vnlesse the principall faculties had seuerall seats, why were there diuers ventricles or cauities made in the braine? And why is one of them more noble then another, vnlesse it be because it is the seat of a more noble faculty.

The 4. argu-
ments.

We will also adde an argument taken from the secrets of Physiognomy. They that haue a large Nowle or backpart of the head are said to haue happy memories: but when the forepart and the forehead doth set outward, the Imagination is the stronger. On the contrary, those that want both these processes are euen by the common people esteemed foolish Idiots: and this is the Philosophy of the Arabians concerning the seats of the faculties. Let vs now come vnto the Greek Family. *Galen* the Prince of this Sect conceiveth that the principall faculties are all established in one place, occupied about the same Images or Notions, do vse the same instrument, to wit, the braine; but their manner of working, saith he, is diuers. In the 8. Book *de vtu partium*, vnder the name *inymoria*, hee comprehenderh the three principall faculties and teacheth that they reside in the whole braine; and in the same book he saith that the principall faculties haue their residence or residence not only in the ventricles but also in the whole body of the braine.

The 5. argu-
ment.

The opinion of
Galen against
the Arabians.

For to what other purpose should the substance of the braine haue beene made so large and ample. In his third Booke *de Placitis Hippocratis & Platonis*, hee saith, that if one of the ventricles be offended, all the principall faculties are therewith affected. And this is confirmed by daily experience and the euent of things. For in the *Epilepsy* or falling sicknesse there is an intercepion of the minde and all the senses, and yet this obstruction doth not occupy all the ventricles. The Phrensie is an inflammation of the braine and his membranes. Now wee observe in this disease that sometimes Reason alone is peruered, sometimes the Imagination, sometimes the Memory: yet who will euer say that in the phrensie one ventricle onely is inflamed? In that kinde of *Melancholia* which proceedeth immediately from the braine and is a cold and dry distemper of the whole substance thereof, yet sometimes I say in that disease onely one faculty is depraued, sometimes the Reason sometimes the Imagination. Wherefore the principall faculties are diffused through all the ventricles & through the whole marrow of the braine. And though they are distinct one from the other, yet doe they exist together in the same particle of the subiect, for one and the same Soule performeth the offices of these different faculties by the vse of diuers meanes and a difference of Tempers. So in one and the same particle of a bone there are diuers faculties included, a drawing, a retaying, an assimilating and an expelling faculty. One of which, though it be affected when as oftentimes the rest are not tainted, yet a Physition will not therefore say that they are discluded in their seats and subiects. As therefore in the stomacke diuers faculties are offended by diuers distempers, the retaining faculty especially by a moyst distemper and the assimilating by a dry, yet are not these faculties separated in diuers parts of the stomacke: so with *Galen* wee think and determine concerning the principall faculties, that the whole substance of the braine is the seat of them all promiscuously disposed therein, which substance if it bee somewhat dry a man shall haue a faster Memory, if somewhat moyst his Imagination or fantasie will be the better.

Obiection.

Answer.

They that follow the opinion of the Arabians doe obiection vnto vs that *Galen* is on their side, for in his Booke *De Oculis*, he placeth the phantasie in the forepart of the braine, Reason in the middest, and Memory in the hinder part. Wee answere that we thinke that Booke is not *Galen* but a bastard falsely fathered vpon him. They adde further that when the imagination is offended *Galen* applyed his remedies to the *Sinciput* and forepart of the head, because there is the seat of the Fantasy. But they doe not consider that *Galen* doth the very same almost in all diseases of the head, as the *Caros*, the *Apoplexy*, the *Phrensie* and *Melancholia*, in the twelfth of his Method and in the second Booke *De Medicamentis secundum locos*, and that not by the reason of the diuersity of seats, but that the force of the Medicine might sooner penetrate into the inner parts of the braine. For that which is applied to the forepart of the head pierceth deeper and sooner because of the thinnes of the skull in that place and the opennesse of the Coronal suture.

A 3. obiection
made.
Places of *Gal.*
for the Arabians.

That place of *Galen* in the second Chapter of his fourth Booke *de locis affectis* seemeth to make more for their purpose, where he writeth. *If when the forepart of the braine is offended, the third ventricle be affected by consent, then will the understanding be depraued.* He seemeth therefore to say that the vnderstanding is not vitiated vnlesse the third ventricle be offended. Again, in the 27. Commentary vpon the first Section *Porrhys*: *If a humor be fastned and stablisch in any part of the braine, those symptomes wil follow which are agreeable as well to the nature of the part*

Answers to
those places.

as to the humor, as for example. If the humor be established in the forepart it will breede a Phrensie in which the Imagination is offended. Hee addeth further. When the matter is transported in the braine out of one part into another, the disease will continew to be of the same kinde, but the symptoms will alter according to the part affected, as sometimes the Imagination will be offended, sometimes the Reason. We answered, that we thinke all the principall faculties are contained in the whole braine, but wee doe not deny but that one faculty is more manifest in one ventricle then it is in another, as the spirits are in this cavity more thin, perfect and better laboured then they are in another.

Obiection.

Finally they obiect, if the principall faculties be not seuered in their places and habitations, why is one ventricle more noble then another? For *Galen* in the 5. chap. of his 3. Book *de locis affectis*, and in the 8. *de usu partium* preferreth the hindmost ventricle to both the rest and the middle to the foremost. And againe in the 6. chap. of his 7. Book *de placitis Hip. & Plat.* hee writeth, that the wounds of the fore ventricles are dangerous, of the middle more dangerous, and of the hindmost most dangerous of all, which seemeth not to happen by reason of the structure, temperament or substance of the braine, because all these are in all places of the brain alike, but by reason of the faculties contained in the ventricles.

Answer.

Some answer that the 3. and 4. ventricles are more noble then the foreward, not because there resideth in these more noble faculties, but because in them the Animall spirit attaineth a further perfection; so that by how much the Liuer is more noble then the stomacke, the Heart then the Lungs, and the left ventricle of the Heart more excellent then the right, by so much and for the same respects the backward ventricles of the braine are more noble then the foreward.

The conclusion
of the ques-
tion.

We conclude therefore with *Galen*: that all the principal faculties do promiscuously inhabite in the same part of the braine together, that they vse the like corporeall Instrument, that is, the substance of the braine, yet they worke after a diuerse manner according to the variety of the Temperament and the Medium.

QUEST. III.

Whether the principall faculties doe depend upon the Temperament of the Braine or upon the Conformation, that is, whether they be similar or organical actions.

That the fa-
culties proceed
from the con-
formation.

Authorities.
The 1. reason.

The second.

The contrary
opinion.
Authorities.
Hippocrates.

Plato.

IT is a most obscure question whether the braine do vse reason and apprehend phantasmes because it is of such a temper, or because of the admirable structure it hath. Some haue conceiued that these faculties are performed only by the Conformation, which their opinion they confirme by authorities and by arguments. *Galen* writeth in his 7. Book *de placitis*, that the cause of wisdom in man is the variety of the structure of the braine and the magnitude thereof. The figure of the head according to *Hippocrates* and *Galen* if it be naturall, that is, sphericall or round, somewhat long, bunching somewhat out before and behind and depressed or flatted on the sides, is a signe of a wise man; and contrariwise a sharpe and Turbinated head like a sugarloafe, which they call *rogon* such as was *Thyr fies* head in *Homer*, is an argument of a dull or stolid foole. Again, all the principall faculties perish when the conformation or structure is vitiated although the Temperament be not yet vitiated, as in the Apoplexy, the Epilepsy and in wounds of the head when the ventricles of the braine are eyther stuffed or compressed. For in the cracking of the Scull, how can the Temperament of the Braine in a moment be altered, or else in the oppletion or filling of the ventricles by any humor? It appeareth therefore that the principall functions are performed only by the structure and conformation of the Braine, and that conformation being vitiated they are presently intercepted.

On the contrary there are others who thinke that the next & immediate cause of these principall faculties is the temper of the marrowy substance and of the spirits of the braine. Let vs heare *Hippocrates*, *Apollo* his eldest sonne and the pillar of the family of Physitians, in his first Book *de diata* teaching the same thing in plaine words. When in the body the dryest part that is the fier, and the moistest part that is the water, are equally tempered, then is a wise man borne.

And these are the words of the diuine *Plato* in *Theateto*. The soule is not wel disposed in a dense or muddy braine, neither yet in a soft or hard braine; for softnes makes men of quicke apprehension

but then they are forgetfull withall, hardnes makes better memories but dulnes of capacity & densi-
contayneth dusky and obscure phantasmes or images. Galen in his 8. Book *de usu partium* saith, *It* Galen.
is better to thinke that the understanding followeth not the variety of composition, but a laudable
temper of that body wherewith we understand: for the perfection of the understanding is not so much
to be attributed to the quantity of the spirits as to the quality. The same Galen in his Book *de Arte*
parua, referreth the causes of wit or capacity to the thick or thin substance of the braine.

This wit he calleth *αγχιμας*, that is, a working capacity, which is defined *ευσοφία*, that is, a
promptitude or readines of Inventing and coniecturing. In the same Book *ευσοφία*, that is, a
facility of learning sheweth a soft and moyst substance of the braine, and *δυσσοφία*, that is, an
ineptitude to learne, a dry and a hard braine. Those that are light witted and inconstant in their
opinions are for the most part of a hot braine, because heate is full of motion. But those that
are obstinate are of a cold braine because cold is sluggish, to which if you adde drought, then
will such men become stubborne and refractory, and hence it is for the most part that the
Authors and fautors or defenders of Schismes and Sects are Melancholy. Galen in his Booke
intituled *That the manners of the mind follow the temperature of the body*, calleth the Soule a con-
sent of qualities, and doth not distinguish it from the temperament.

In his Commentary vpon the 6. Book *Epidemion* and vpon the 6. Aphorisme of the 2. Se-
ction, as also in the 6. chap. of his Book *de locis affectis*, he sty leth the temperament of the brain
the *Minde*. For so he expoundeth that Aphorisme of Hippoc. Melancholy men become Epi-
lepticall and Epilepticall men Melancholy; as the humor ascendeth into this or that part so is
there a transmutation made of these diseases. For if the humor be transfused into the body &
ventricles of the braine then they become Epilepticall, if into the minde they become Melan-
cholicall; where by *Minde* he vnderstandeth the Temperament. For the disease called *Melan-*
choly is a cold and dry distemper of the braine. But when Galen called the Soule a Temper, he
doeth not conceiue that that Temper is the forme of a reasonable man, but the *forma medica*,
because that onely falleth into the Physitions consideration.

Galen calleth
the Soule a
temper.
how & why.

For that which can neither be preserued when it is present nor restored when it is absent,
that doth not at all belong vnto the Physition: but the intellectuall Soule can neither be pre-
serued being present nor restored being absent; onely the Temperament may be maintained
when we haue it, or restored when it is lost. The Temperament therefore only is the Physicall
forme of a man, because the Physition considereth a mans body not as it is Natural consisting
of Matter and Forme, but as it is subiect to sicknesse, and againe liable to Physicke. And from
hence some men doe imagine that it is sufficiently prooued that the principall faculties of the
soule are not exercised by the structure or conformation but by the temper of the braine.

Our opinion concerning this question is, that the efficient cause of all the functions is ney-
ther the Temper alone, nor onely the wonderfull structure of the braine; but the intellectuall
Soule which notwithstanding admitteth both these causes: one Organically which is the ampli-
tude or largeness of the braine and of the ventricles and the plenty of the spirits: the other si-
milar which is the Temper of the marrowy substance and of the spirits. From hence we gather
that *Raticionation*, that is, the vse of Reason is neither absolutely an Organically action because
it is impaired in those that are Melancholicall and Phreneticall, when the structure of the
braine is not at all violated; neither yet purely similar, because the braine is offended when his
ventricles are compressed or stuffed vp, all be the Temperament be not offended.

What wee re-
solue of.

Furthermore this *Raticionation* is neither inchoated nor perfected by the Temperament a-
lone, neither yet performed by any particle of the brain; but is an action mixed or compoun-
ded of an Organically and Similar, such as is the action of the heart and the stomacke. For the
heart indeed is moued and hath his pulsation from an ingenite faculty and proper Temper of
his own: But it could neither haue been contracted nor distended vnlesse it had been excaua-
ted or hollowed into ventricles.

QUEST. IV.

Of the vse of the braine against Aristotle.

IF euer that great interpreter of Nature Aristotle the Prince of the *Peripateticks*, doe
lesse sufficiently acquite himselfe, it is in the matter of Anatomy, and more especially
in that he hath written concerning the vse of the braine in the 7. chap. of his 2. Booke

The vse of the
braine after
Aristotle.

Aristotle
confuted.

A very strong
Argument.

The true vse
of the braine.

What Auerrhoes
opinion is.

But confuted.

Where these
questions are
disputed.

depart. *Animal*. where he cannot be redeemed from palpable absurdity. The braine, saith he, was only made to refrigerate the heart. First, because it is without blood and without veines; and againe because a mans braine is of all other creatures the largest, for that his heart is the hottest. This opinion of *Aristotle*, *Galen* in his 8. Booke *de v'su partium* confuteth by these arguments. First, seeing the braine is actually more hot then the most soulerie ayre in Summer, how shall it refrigerate or coole the heart? Shall it not rather be contempered by the inspiration of ayre, which it draweth in and as it were swalloweth from a full streame? If the *Peripateticks* shall say that the externall ayre is not sufficient to refrigerate the heart but that there is also required an inward bowell to assist it: I answer, that the braine is farre removed from the heart and walled in on euery side with the bones of the Scull. But surely if Nature had intended it for that vse, she would either have placed it in the Chest or at least not set so long a necke betweene them. The heele, saith *Galen*, hath more power to coole the heart then the braine: for when they are refrigerated or wet, the cold is presently communicated to the whole body, which hapneth not when men take cold on their heads. Beside, the braine is rather heated by the heart, then the heart cooled by the braine, because from the heart and the vmbles about it, there continually arise very hot vapors, which being naturally light do ascend upward. Adde hereto this strong Argument which viterly subuerteth the opinion of *Aristotle* and the *Peripateticks*. If the braine had beene onely made to coole the heart, what need had there bin of so admirable a structure? what vse is there of the 4. ventricles, the Chambered or Arched body, of the webs and textures of the Arteries, of the pine-glandule, of the Tunnel, of the Testicles and Buttocks, of the Spinal marrow and of the manifold propagations of the sinews?

Finally, if this were true that *Aristotle* affirmeth, then should the Lyon which is the hottest of all creatures (witness his continuall disposition to the Ague) haue had a larger braine then a man, and men because they are hotter should haue larger braines then women; which things because they abhorre from reason & sense, we doubt to not affirme that the brain was created for more noble and diuine imployments then to refrigerate the heart. The body therefore of the braine was built for the performance of the Animall, Sensatiue, Motiue and Principall functions, and it is hollowed into so many ventricles and furnished with so many textures and complications of vessels; for the auoyding of his excrements, for the preparation and perfection of the Animall spirits; besides, the Nerves serue as Organs to lead out the same Animall spirit together with the faculties or motion and sense vnto the senses and the whole body. *Auerrhoes* (*Aristotles* Ape and where occasion is giuen, a bitter detractor from Physitions) endeauoreth to excuse *Aristotle* and saith, That the braine doth therefore refrigerate the heart because it tempers the extreame heat of the vitall spirits. But let vs grant that the braine tempers some spirits, yet it will hardly temper the spirits of the heart and of the large arteries, if it at all temper those spirits which are contained in the substance and membranes of the braine; which spirits so tempered seeing they do not returne vnto the heart, how shall they temper the heat of the heart? *Alexander Benedictus* in the 20. chap. of his 4. Booke seemeth to follow the opinion of *Auerrhoes*. *Albertus Magnus* a man better stored with learning then honesty, although he be a *Peripatetick*, yet in this point he falleth from his Maister *Aristotle*, and saith in his 12. Booke *de Animal*. that the braine by his frigidity doth no more temper the heat of the heart then the ficcity or driness of the heart doth temper the moysture of the braine.

Whether the braine be the originall of the sinews?

Whether the Nerves be continued with the veines and Arteries?

Whether the Nerves be the Organs of sense and motion?

Whether the Nerves of motion differ from the Nerves of sense?

Why the sense may perish, the motion being not kindered, or on the contrary?

Whether the faculty alone or a spirit therewith doe passe by the Nerves?

By which part of the Nerue the inner or the viter, the spirit is derined.

All these questions and difficulties with their resolutions you must seeke for in the third part of our book of the vessels. The rest of the questions we now prosecute.

QUEST.

QUEST. V.

Whence it is, that when the right side of the Head or Braine is wounded or enflamed, a Convulsion falleth into the opposite parts.

WE haue a double Probleme heere to discusse. The first, how it commeth to passe, that when the right side of the head is wounded or enflamed, it oftentimes falleth out that the left parts of the body suffer Convulsion. The second, why one part of the braine being smitten or obstructed, it sometimes happeneth that the contrary side of the body is resolu'd or becommeth Paralyticall.

Both these questions haue in them many difficulties. For the affects or diseases almost of all the parts are communicated *ἁρτίῳ*, that is, by rectitude, not *ἀντιῳ*, that is, by Contrariety, because the right side with the right, and the left with the left are *ὁμοῦ*, that is, haue a similitude of substance. And therefore when the Spleene is affected the left side is pained, and when the Liuer is offended the right. And in the 2. Section of the first Booke *Epidemion*. The paines of the sides, as pleuresies and such like are *ἐκείῳ*, that is, on the same side; so also is the Tension or swelling of the *Hypochondria*, the tumor of the spleene & the bleeding at the nose. We will first therefore entreate of Convulsion and then of the Palsy.

That the opposite parts suffer Convulsion *Hippoc.* first of all men taught vs in his Booke *De vulner. Capitis*. By opposite parts he vnderstandeth the parts sometimes of the head alone, sometimes of the whole body. Of the head alone, whereas he writeth that the veines which runne through the temples are not to be opened, because there is daunger of convulsion, of the right side if the left veine be opened, and on the contrary.

Of that convulsion which affecteth the rest of the parts of the body, hee maketh mention in the same Booke. If (saith he) the Bone be purulent, then will Pustules arise in the tongue, then the patient wounded will dye idle-headed, and for the most part the other side of his body suffereth Convulsion, for if the right side of the head be wounded then will the Convulsion occupy the left part of the body, and on the contrary.

In the 5. Booke *Epidemion* he telleth of a wench whom he calleth *Puella Omilæ*, who had a bruise on the right side of her head in the middle of Summer and suffered convulsion on the left parts. *Antonius* had both his hands conuelled when hee was stricken with a stone in the middle of the *sciniput* or fore-part of the head about the mold.

In the 7. *Epidemion*. In the history of the sonnes of *Phanius* and *Euergetus* who were wounded in their heads. In such (saith he) it happeneth that they fall to vomiting and suffer Convulsions, and that in the left parts if the right side be wounded, and in the right if the left. Wherefore I gather out of *Hippocrates* these two things. First, that Convulsion doth not alwayes follow but onely when there is suppuration made, or whilst it is suppurating, or when there is a great inflammation. Againe, that all that are wounded doe not suffer Convulsion but the most, so that it is not perpetually or vniuersally true, that if one part bee wounded, the contrary part is conuelled.

To assigne the cause of the 1. convulsion it is not hard; for if the right temporall Muscle bee wounded or resolu'd, yet doth not a convulsion properly so call *primarily* and of it selfe fall vpon the opposite Muscle, but onely by event, because all the muscles are either *Antagonists* that is *Aduersary*, or *Congeneres* that is a *Kin*: if they bee *Congeneres* then the resolution or section of one causeth the convulsion of the other: but if they be contrary or *Aduersary* so that their motions succede one the other, then one of them perishing the other is necessarily taken away. For if the muscle which extendeth a part be cut, the part will indeed be bent, but it will so alwayes remaine; because it can no more be extended, and so the convulsion is accidentary and improperly so called.

But the nature of the other convulsion which is of the rest of the parts of the body not of the head alone, is much more obscure, notwithstanding *Hippocrates* in the places before quoted seemeth to acknowledge the cause to be the malignity of the *pneuma* or matter, which launcing the Membranes which are of an exquisite sense and pricking the original of the sinnew stirreth vp a depraued motion. Now there passeth from the wounded part into the sound part sometimes a breath alone, sometimes a portion of the malignant *ichor* or humor. The breath vapoureth a way thorough insensible passages, but how the *ichor* or thin humor should passe from the wounded part to the opposite side it is not easy to declare.

The affections of the parts are communicated according to Rectitude.

That the opposite parts are conuelled *Hip.* authority.

Many histories

Two things gathered out of *Hippocrates*

Why one temporall muscle is conuelled when the other is wounded.

The cause of opposite convulsion is a malignant quality.

How the Ichor
is carried out
of the sound
part into the
offended.

Instances.

Hippocrates.

Puella Omileas.

Two obscure
questions.

How the Ichor
passeth into the
opposite part.

Why the woun-
ded part is not
conuulsed.

It must needs bee either transmitted, or must fall downe, or be Propagated or finally Expressed. No man will say it is transmitted out of the wounded part into the sound, because the weaker part doth not vse to exonerate it selfe into the stronger; neyther doth it fall downe because all such sinking downward is perpendicular, that is, directly downward, for it followeth the motion of the humour, which motion seeing it dependeth vpon the Elementary forme, as Philosophers conclude it must be right and simple: wherefore it is eyther propagated or expressed, and both these I heere acknowledge. It is propagated if it abound in quantity; if the substance of it bee very thinne, if the quality bee verie sharpe: so Choler which is of Temper exceeding hot and raging when it breedeth an *Erysipylas* or Saint Anthonies fire in the inward parts, diffuseth it selfe sometimes euen to the outward parts also. So saith *Hippocrates* in a Squinsey of the *Larynx* or throtle, both the necke and top of the cheest are very red, *per erysipylas*, that is, by consequence or succession. What therefore shall hinder the diffusion of a thin Ichor through the whole membrane if the inflammation be come to his height? But if there bee not that plenty of Ichor that it can bee propagated, yet may there be made an Expression of it out of the right side into the left; and often there is from lower parts to the vpperward a *basitis*, that is, a Compression. Now Expression is made by compression, compression by suppuration, which whilest it is a making doeth distend the neighbour parts, because the working or boyling humour occupieth a greater place; and hence come paines and Agues in the time whilest the *Pus* or Matter is in confection, and therefore *Hippocrates* saith that conuulsion is especially then induced when suppuration is a making.

In *Puella Omileas* it is likely that the Ichor was not diffused, but expressed out of the wounded part into the part opposite. It may happen that a very little as it were droppe of the Ichor may moue a conuulsion, as also a venomous vapour, by goading the membranes of the nerues which are of most exquisite sence. Wherefore the humour which breedeth the conuulsion is oftentimes expressed or propagated from the diseased into the sound part, neither is it necessary alwayes that an Ichor should be expressed or propagated, it is sufficient if a malignant ayre breath out of it.

But heere wee obserue two things very obscure and intangled. First, how the Ichor can passe out of the wounded side into the contrary, seeing that the braine is distinguished into the right side and the left by a proper midriffe of his owne and that exceeding thick, which is a duplication of the *Dura Meninx* called the Sythe, because it is like a Mowing Sythe or Sicle? The other why when as the same acrimony of the *Pus* or quitture pricketh the membrane of the wounded part, it doth not stir vp conuulsion in the same but in the opposite part.

The dissolution of the former is fetched from Anatomy. The hard Membrane which toucheth the Skull in the vpper and Exterior part is wholly continuat and lined (as it were) or smeared ouer with a watry humour; betwixt it and the bone of the Skull is the purulent matter gathered, which may bee both Expressed and Propagated out of the right side into the left by the continuity of the Membrane, and furthered by the orbicular figure of the head.

A small portion of the Ichor expressed out of the affected into the sound side, sometimes by reason of the tenuity sweateth through the membranes into the marrow of the braine, and out of it into the nerues; whence comes their inflammation: sometimes by the outside of the membranes it falleth into the spinall marrow which is inuested with the same membrane, where goading the originall of the nerues it procureth a conuulsion by sympathy or consent, so that when the membranes are vellicated or enflamed a conuulsion sooner ensueth then if the internal or marrowy substance of the nerues were affected.

But why is the conuulsion not in the wounded but in the opposite part? It is obserued that sometimes when the right side of the head is wounded the right parts of the body are also conuulsed, sometimes the opposite parts only, oftentimes both together when (sain *Galen*) the inflammation toucheth the originall. It is not therefore perpetually true, that when one part of the head is wounded the opposite part is conuulsed, but because it hapneth so for the most part, let vs enquire the reason thereof.

The conuulsion is in the opposite not in the wounded part, because the purulent matter which is expressed or diffused out of the wounded into the sound part hath no issue but is there stabled or gathered and breedeth an inflammation; and from thence comes the conuulsion: but the *sanies* or matter which gathereth in the wounded part hath free egress by the wound and

and by the section of the bone, and so the Membrane is not affected. And this haply Hippoc. meaneth when in the history of that wench he said, that the left parts suffered convulsion because the contusion was on the right side. We may also assigne another reason of this convulsion and that very probable. The wounded part is not conuelled but the opposite, because the faculty of the wounded part is extinguished and dissolued, and the temperament which is the cause of all actions is notably depraued; wherefore though the faculty bee prouoked yet it answereth not, neyther doth any motion follow such prouocation, but the contrary part answereth the motion. Hippocrates. Another reason of it.

Now that vpon a suppuration or notable inflammation the part is almost mortified Hippoc. is witnesse in his booke *de vulneribus capitis*: but the opposite part hauing a quick sense is presently contracted and draweth into consent with it all the nerues of the same side; and so convulsion followeth *κατ' ἑν* by a rectitude of vessels. And this our coniecture the place of Hippoc. about named maketh good. For when the convulsion falleth vpon the opposite part then the case is desperate, pustules arise in the tongue, & the patient dyeth in a *delirium* or light phrensy. Hippocrates

QUEST. VI.

Why when the right side of the head is wounded or obstructed, the opposite part is resolved or becommeth Paralyticall.

Concerning the Palsy the difficulty is greater, the knot harder to cleare, namely, why when one part of the head is wounded or one of the ventricles of the braine obstructed or compressed, the opposite parts are resolved or become Paralyticall? That it is most true the examples are infinite, and all Physitions both ancient and moderne in their writings do agree vpon it. Hippocrates maketh mention of this kinde of Palsy in his booke *de vulneribus capitis* and in *Coacis praxionibus*. Those (saith he) that become impotent of wounds in their head do recover if an Ague without horror ouertake them, otherwise they become apoplecticall in the right parts or in the left; that is, paralyticall. For Hippocrates often calleth the leg taken with the Palsy *Crus Apoplecticum*. In the history of the sonnes of Phanius and Euergetus in his 7. booke *Epidemion* he writeth that they become impotent (if the wound be in the right part) on the left side, and on the right side if the wound were on the left part. Aretaeus in the 7. chap. of his 1. Booke *de Causis & signis diuturnorum morborum* is of the same minde. If (saith he) the head be wounded at first on the right part, the left side is resolved; if on the left, the right side. Salicetus setteth this downe for a Catholike or vniuersall Theoreme or *Maxime*. Whensoever any man is wounded in the head so that a Palsy happen thereupon, if the wound be in the right part of the head, the left side will be paralyticall and contrariwise. The same hath Iohannes de Vigo obserued: and Hollerius in his *Commentaries in Coacas praxiones Hippocratis*. And we also saith Laurentius, haue obserued the same. That the opposite parts are resolved, prouoked by authorities. A story out of Hippocrates.

Wherefore that it is so, there is no controuersie, all the question is, why and how it commeth so to passe, and that indeed is much disputed. Some imagine that the nerues in their originall are so implicated that the right nerues run along the left side, and the left along the right side, intersecting themselves in manner of a Saint Andrewes Crosse, which intersection is called *χιασμός*, and therefore it is, say they, that when the right part is obstructed or otherwise affected, the left side is conuelled or resolved, and on the contrary, because the originall is affected. And this is the opinion of Cassius and Aretaeus. Cassius thought that the nerues doe so take their originall from the Basis of the braine, that those which arose from the right part were carried into the left, and those which arose from the left side into the right, crossing one another ouerthwart. Aretaeus is of the same opinion. The right nerues, saith he, do not proceede directly into the right parts vnto their terminations; but as soone as they spring vp they cut ouer to the other side crossing one another like the letter X, which the Gracians call *χιασμός*. But the leuity of this opinion needeth no confutation. For ocular inspection which we call *αυτοψία* reacheth vs that all the nerues which arise out of the marrow of the braine are altogether distinguished and separated in their originall, progresse & insertion; excepting only the opticks which in the middle of their iourney do meet & that necessarily, that they might passe directly to the apple of the eye; that they might not grow flaccid or loose in their long iourney being very soft; that the simple and single object of the eye might not seeme double: and finally that the formes and Images of visible things might be vnited. Only therefore the optick nerues do meet, Divers opinions show this palsy commeth The first. Of Cassius and Aretaeus that the nerues crosse one another. Confuted. χιασμός. None but the opticks doe intersect.

meet, yet so that they neuer intersect or crosse one the other. We haue also of late obserued, saith *Laurentius*, that the nerues of the second coniugation haue beene continuall in their originall.

As for the nerues of the spinall marrow, the right are separated from the left, neuer cutting one ouerthwart another. It is therefore absurd to referre the cause of the convulsion and palsy which hapneth on the aduerse side to the intersection of the nerues and their Crosse permutation as *Aretæus* would haue it, because it is a meere fable.

The 2. opinion
that the spirits
passe by the ar-
teries which
intersect.

Some conceiue that not the Nerues, but the Veines and small Arteries of the Braine are implicated first in the Basis of the Braine, then in those two labyrinthian textures, the one called *Choroides*, the other *Rete mirabile*, so that they are diuaticated out of the right side into the left, and out of the left side into the right. They thinke therefore that when the Ventricle on the right side of the Braine, and the parts thereof are obstructed or compressed, the left side is conuelled or resolued because the entercourse of the Spirits is intercepted by the oppression or obstruction of their common fountaine, and at length by stopping of the way of the Spirit which they perswade themselves is communicated to the whole body by the Arteries not by the marrowey and inward substance of the Nerues. I cannot but acknowledge this conceit to bee very ingenuous and seemingly true if it were not that it is contradicted by the principles of Anatomy. For to winde vp the matter in a few words, this opinion taketh these two positions for good. First, that the Vessels doe intersect or crosse one another, and againe that the Animall Spirits are conuayed by Vessels not by the marrow of the nerues; which, how dissonant they are from the truth may thus be demonstrated by the two common and most competent Iudges of all Controuersies, reason and sence.

Confuted.

The diuatica-
tion of the ves-
sels of the
braine.

All the vessels which irrigate or water the whole body of the braine and his membranes are propagated from the internall Iugular veine and from the arteries called *Carotides* and *Cervicales*: now we are taught by *Autopsia* or ocular inspection, that the diuatication of these is on this manner.

The Sinus or
duplication of
the Dura Ma-
ter.

The right Iugular veine powreth the blood into the right sinus of the *dura mater* as it were into a Cisterne, and the left into the left; out of the *conuergent* or *Concourse* of these two ariseth the third Sinus, which running through the length of the sagittal suture is conuayed to the top of the nose, and from this many small veines are diuersly dispersed into the *pia mater*: the fourth Sinus concaued between the braine and the After-braine determineth at the buttocks of the Braine.

These Sinus as it were riuers substituted by Nature instead of vessels, doe disperse the blood on all hands, and from them as out of a presse, the blood arriuing vnto them from the Iugular veines, is expressed into the whole body of the braine. The Iugular veines therefore doe meete and vnite themselves in the third and fourth Sinus of the *Dura mater*, but yet are neuer so implicated that the right doe passe vnto the left side, or the left vnto the right; there is no intersection of these vessels, no *χιασμός*. Neither is there any intersection of the right *Carotidall* or *sleepy arteries* with the left, because they doe not powre vitall spirits into those Sinus or duplications of the membrane as the veines doe the blood, neither are the right implicated with the left, but each artery maketh his owne texture, the right artery the right texture and the left the left.

The arteries of
the braine doe
not intersect.

These textures or complications which are manifest in the vpper ventricles and called *Plexus Choroides* doe neuer so intersect themselves that the right should passe vnto the left, the left vnto the right parts, for the vpper Ventricles are disseuered by their proper wall or distinction.

Experience.

And if they say that the *Carotides* are implicated in the basis of the braine at the sides of the buttocks and there intersect themselves. I will indeed confesse that the arteries of the same side are implicated, that is, are contorted manifold like the tendrilles of a Vine crumpled vp together for the better preparation of the spirits: but that they intersect themselves and from the right side passe vnto the left, that I constantly deny. For the holes of the buttocks do stand off one from the other, through which the arteries ascend to the basis of the braine, and from them *κατ' ἑξῆς* or by a right line to the vpper ventricles: which he that will not otherwise beleue may thus proue by his owne experience. Put a hollow Probe of Bugle into the right *sleepy artery* and blow it, and you shall perceiue that the arteries of the right side will bee distended more then the arteries of the left. Let vs therefore cleare our conceits of this mist and cloud of error concerning the intersection of the vessels which *Autopsia* it selfe conuinceth to be a forged conceite.

Befide

Beside experience we have good reason also against it: for if we admit this interfection of the vessels, then it will necessarily follow, that whensoever the right parts are stuffed or compressed the left parts shall be resolved; because the course of the spirit is intercepted. But wee finde it often to fall out, that when the right Ventricle is obstructed the parts of the same side are resolved. But let vs for disputation sake admit (though wee doe not grant it) that those small Arteries and the complications of them do intersect one another, must it thereupon needs follow that when the vessels are compressed the Palsye should seize vpon the contrary side: The Arteries are onely conceptacles of the Vitall spirits. Those Vitall spirits do onely conferre their helpe to the cherishing, rowzing vp, and restoring of the in-bred heate of the particular parts, but affoord no helpe at all to Motion or Sense. Now in the palsy the part lieth though the Motion and Sense be both of them quite intercepted. Wherefore by the Arteries the Animall Spirit is not conueyed which is the Author of all Sense and Motion.

Reason.

The arteries do not conuey the animall spirits.

I know well that when the Iugular Veines and the Carotidall Arteries are obstructed, the Caros Apoplexy and Lethargy do follow; whence the Carotidall artery is called *Lethargical & Apoplectical*, and Hippocrates vseth to call that kinde of Apoplexy, *τὸν ἐκ τῆς ἀρτηρίας*, the inter-ception of the Veines: but this Apoplexy hapneth but by accident and is curable, wherein access is denyed to the vitall spirit which ministrerth matter to the Animall. But the Question in this place is of a true Palsy which happeneth vpon the exolution, made faction, and (that I may vse the Arabians word) Mollification of the Nerues, or when the wayes of the Animall spirits are shut vp or intercepted. These wayes are the Nerues, which albeit they haue no conspicuous cavity, yet is their inward substance altogether spongy, through which the Animall faculty and those impetuous spirits which Hippocrates calleth *τὰ ἐνδομυῖνα* do easily finde their way.

A light kinde of apoplexie whence.

Many learned men there are, who will not admit of this truth, and especially among the late writers *Rondeletius* striueth to proue that the Animall spirit is conueyed through the arteries not through the marrowy substance of the nerues: the only vse of the marrow he acknowledged to be, that like flockes it may sustaine and strengthen the smal and slender vessels. *Argenterius* also thinketh that the spirits neuer forsake the Arteries.

Rondeletius opinion that the animall spirits passed through the arteries.

It was an old opinion of *Praxagoras* as *Galen* remembreth in the seventh Chapter of his first Booke *De Placitis Hippocratis & Platonis*, that the Nerues were continued with the Arteries, and that the Nerues were nothing else but Arteries become now slender and small. But the weakenesse and insufficiencie of this opinion is hence conuined, because the Inter-costall Arteries are small and threddy, and the Arteries of the braine which make the two textures thereof as fine as haire, and yet no man euer durst call them Sinews. But of this we shall haue better occasion to dispute in our Booke of the vessels. In this place it shall bee sufficient to haue said that the Animall spirits cannot passe by the Arteries, because they were destined and ordained by Nature for the transportation of the Vitall spirits: now two spirits distinct in forme and kinde as wee vse to say, cannot bee conueyed by the same Vessels. When the Opticke Nerue is obstructed the action of the sight perisheth, are there then any small Arteries intercepted? Or is their interception the cause of blindness? Nothing lesse, for the part should bee vterly extinguished if it were no more illustrated with the beames of the Vitall spirits. Wherefore when the marrowy substance is affected, when the spondils or racke-bones are luxated the body is often resolved, because the marrow of the Nerue is pressed, by reason of which compression the passage of the Animall Spirit is intercluded.

Praxagoras opinion out of Galen.

Confuted.

That the animall spirits passe not by the arteries.

Diuers arguments.

In those that are afflicted with the Stone, the legge on the same side becommeth stupified, the Nerues and Muscles which are ordained to bend it being compressed by the Kidnie lying thereupon. As for those small Arteries which run thorough the Membranes that couer the Nerues they minister the Spirit of life vnto the Nerues, not the faculty of Sense and Motion. Againe, the Arteries of the Braine doe not essentially differ from Arteries, but other where the Arteries neyther engender nor containe Animall spirits, therefore not in the Braine.

Adde hereto, that the forme of every thing is stamped vpon the aliment and the spirit, onely by the substance of the part: now in those complications there is onely a power to prepare and as it were to delineate the spirits, their forme they haue onely from the Marrowy substance of the Braine. Finally, as the Braine by reason of this Marrowy substance is called the Braine, and this Marrow is the principall part of this noble Organ the seate of

of

of the Memory, Reason and Discourse: so I thinke that the chiefe part of the nerue is the marrow thereof, which carrieth the commandement of the Sensatiue and Motiue faculty, not only by irradiation but by a corporeall spirit. And therefore it is that *Galen* in his 8. Booke *de usu partium* calleth the braine *Nervum amplissimum & mollissimum*; A soft and large nerue; and againe he calleth a nerue *Cerebrum durius & resiccatum*, A hard and dried Braine. But if (as *Rondeletius* conceited) the inward part of the nerue had beene only ordayned for the establishing and sustaining of the small arteries ioyned to their membranes, then certainly is the Marrowy part of the nerue the basest and most ignoble.

Let therefore the opinion of *Galen* and of the ancients remaine with vs as current and canonicall, to wit, that the Animal spirits passe through the marrow of the nerves not through the arteries.

The cause of
the palse in
the opposite
part.

These things being thus established, it remaineth that we discover the cause of the Palsie which happeneth on the contrary side to the wounded or affected part. When the right part of the Head is wounded a portion of the *Ichor* may fall *anti ēv* by *Refirude* into the right fore ventricle; now out of it into the third (which is common) there is a manifest passage, (this ventricle *Galen* calleth the middle either because it is in the very center of the Braine, or else because it is situated betwixt the 2. vppermost and the 4. ventricle which is the lowest) and the humor contained in that ventricle is as it were in the center of the Braine. Wherefore if it follow the Motion of the Elementary forme it must fall into a lower place: now the sound part is alwayes the lower, because the patient euer leaneth or lyeth vpon the sound side not vpon the fore side for auoyding of paine. What therefore should hinder but that the humor may fall out of the 3. ventricle into the 4. and from thence into the spinall marrow on the opposite part vnto that which is wounded, and so that part become Paralyticall or resoluē? The Braine is not as some haue dreamt diuided from the top to the very bottome; the vpper ventricles determine into a common cavity into which they thrust down their superfluities. This common cavity is directed into the 4. ventricle which is common both to the after-braine & the spinall marrow. It is not therefore against our Anatomical principles or grounds, that *Matter, Flegme and Blood*, may be transmitted from the right ventricle to the 3. and from hence through the 4. ventricle into diuers parts of the spinall marrow, now into the right side and now into the left as either of them is lower or weaker.

Another reason.

Another reason also may be brought of the palse in the sound part not in the affected, because Nature vseth to auoid the excrementitious humor by the wound, as sometimes by a flux of blood, sometimes by quitture, sometimes by Medicines which draw away and exhaust the humor either sensibly or insensibly, so that the affected part is wel purged by some or more of these meanes; but the opposite part which is not expurged is easily affected either by sympathy or when the matter is transmitted or falleth vpon it.

Another?

Some think that almost all the spirits do flow to the part wherein the tumor or inflammation is, whence it is that the opposite part being defrauded of them is resoluē.

QUEST. VII.

What is the Nature of the Animall Spirit, what is the manner of his Generation and the place thereof.

WE haue sufficiently proued by strong Arguments that to Motion and Sense is required not onely an influence of a faculty but also of a corporeall spirit. Now what name we shall giue this spirit, what his nature is, what is the manner and place of his generation we will breifely declare.

What is the
animall spirit,
Galen.

Galen calleth this spirit euery where *Animalem* the Animall spirit, because the Soule vseth it as her immediate Organ for the performance of all the animall functions of sense and motion and those which we commonly call principall.

This spirit in the 17. Chap. of his 6. Booke *de Usu Partium* he defineth to be an exhalation of pure blood. Some thinke it to be a part of the liuing braine, yea both a Similar and an Organicall part: Similar as it hath a certaine and designed temper, Organicall as it is thin, lucid, subtile, pure and moueable.

This Spirit some haue thought doth not differ in kinde and Nature from the Vitall but onely in accidents, as in temperament, place, the originall *à quo*, and the manner of diffusion.

tion. For the Animall spirit is moyster and more temperate, the Vitall hotter. The Animall commeth from the braine, the Vitall from the heart; the Animall is dispersed through the nerues for Motion and Sence; the Vitall through the arteries to maintayne the life.

We are of opinion that these two spirits are of a diuerse forme and kinde, as Chylification is diuerse from Sanguification. For the Organs are diuers, the faculties diuers, diuers is the manner of Generation: and as the Aliment by a new concoction receiue a new forme and so a new denomination, so it is with the spirits. *Galen* in a thousand places distinguisheth this Animall from the Vitall spirit, whatsoever some new Writers say to the contrary. In the 5. Chapter of the 12. Booke of his Method: *The Animall spirit* (saith he) *ariseth out of the Brain as out of his fountaine.*

The demonstration of the Vitall spirit is not euident, but yet it is agreeable to reason that it is containd in the heart and the arteries. And if there bee any Naturall spirit, that is included in the Liuer and the veines. In the 7. Chap. of his 3. Booke *de locis affectis* *Galen* saith, *The Epilepsie* hapneth in the Braine when the humour hindreth the Animall spirit which is containd in the ventricles thereof that it cannot haue yssue out. In the 10. Chapter of his 16. Booke *de usu partium*. The complications of the arteries doe nourish the Animall spirit contained in the braine, which differeth much in Nature from other spirits. In the third Chapter of his 7. Booke *de placitis Hip. and Plat.* The spirit which is contained in the arteries is indeed Vitall and so is also called; that which is containd in the braine is Animall, not that it is the substance of the Soule, but because it is the Soules first and most immediate instrument. The same also hee writeth in the 4. Chapter of his 9. Booke *de usu partium*. In the 8. Chapter of the 9. Booke *de placitis Hip. & Plat.* and in the 5. Chapter of the ninth Booke *de utilitate respirationis.*

By all which places we may gather that *Galen* made a difference betweene the Vitall and the Animall spirits. And truely that there should be an Animall spirit it was very necessary; first to conuay vnto the parts the faculty of Motion and Sence which is not fixed in them; and againe that we might bee more apprehensie of outward accidents. For seeing that the Organs of the Sences ought to bee affected on the sudden by sensible things, it was fit they should not be altogether solide, but houed and fulfilled with spirits that they might the sooner be altered. Moreouer these spirits doe transerre the species or formes of all outward things perceiued by the outward Sences vnto the braine as vnto a Censor or Iudge. The same spirits doe conceiue in the braine the images of those outward thinges, so that the Animall spirit may be called the place and promptuarie of the species or formes. So in the *Vertigo* or *Giddinesse* neither the thing it selfe, nor the Image of it, nor any thing beside the spirit is rowled about, and yet notwithstanding all things seeme to him that is so affected to runne round. Wherefore this spirite is necessary both for motion and sence. As for the principall faculties, to the performance of all their functions the braine vseth the ministry and helpe of this spirit; so that it worketh both within the braine and without the braine: within the braine it helpeth the principall faculties; without the braine it conferreth Motion and Sence. Now it is not onely abiding in the ventricles but also in the pores and in the whole marrowey substance of the braine, so that in the pores and substance it is communicated to the principall faculties: In the ventricles it serueth more immediately for Sence and motion.

Furthermore this spirit which is the immediate Organ of Sence and Motion and of the principall faculties, is indeede of one kinde notwithstanding it is esteemed manifold according to the variety of the objects and instrumts where about it is imployed; which thing *Aristotle* elegantly hath taught vs in the last chapter of his 5. booke *de generatione Animalium*.

The spirit saith hee in Naturall things is like the hammer in the Art of the Smith, that is to say, but one instrument, yet profitable for the performance of many offices. *Aetnarius* compareth it to the beames of the Sunne, which though they bee all of one kinde yet they become vnlike when they light vpon different colours.

It remayneth now that we should manifest vnto you the Matter of the Animall spirit, and the manner of his generation.

The matter of it is double, Ayre and the Vitall spirit.

The Ayre is drawne in by the noethrills; the Vitall spirits are conuayed through the Arteries called *Carotides* and *Cervicales* into the basis of the braine. With this Ayre the spirit is nourished, and therefore *Galen* acknowledgeth a double vse of Respiration, to witte, the conseruation of Naturall heate and the Nutrition or Generation of the Animall spirits. Now if the passage of these two matters to the braine be intercepted, then will there be no generation

Yy

The vital and animal spirits differ in form & kinde.

Diuers places in *Galen*.

The necessity & vse of the animal spirit.

How the animal spirit is manifold.

The matter of the animal spirit.

tion of Animall spirits. If the *sleepy* arteries be bound an *Apoplexy* ensueth, if *Respiration* be prohibited, the Creature dyeth instantly and is deprived of Sence and Morion.

Containe places of *Galen* concerning the Animall spirit reconciled.

Galen concerning this poynt seemeth to differ from himselfe, but wee will reconcile those different places well enough. In the 5. Chapter of his booke *de usu Respirationis* he saith, that in a living creature he tyed the *Sleepy Arteries* and yet the creature perished not: therefore it followeth his Animall spirit was nourished onely with Ayre not with the vitall spirit. In his third booke *de placitis* and in the ninth booke *de usu partium*, he writeth that the Animall spirit may bee cherished and sustained with the vitall conueighed by the Arteries and maketh no mention at all of the Ayre.

Wee answer, that the Animall spirit may bee for a little time sustained if it bee deprived of cyther of his Aliments: for there is stored vp a supply against time of need in those two complications or textures called *Plexus Choroides* & *Rete mirabile*, but long that supply will not maintaine them.

Where the Animall spirit is prepared.

The preparation of this spirit is made in those Labyrinths of the small Arteries, their coction or elaboration (as some think) in the ventricles; and finally, their distribution into the whole body of the braine and into the sinewes.

They therefore are in an error who do conceiue that this spirit attaineth his proper forme and specifical difference in those textures. For all the complications of vessels as well in the braine as in the testicles and other parts are ordained onely for preparation, but the forme and difference of a thing is supplied by the substance of the part, both to the Aliment and to the spirit.

Where labored and perfected.

Wherefore we conclude, that in those complications the spirits are prepared, that in the ventricles they are boyled and labored, but receiue their vitermost perfection in the substance of the Braine.

QUEST. VIII.

Argenterius his opinion concerning the Animall spirit confuted.

Argenterius an acute Scholler indeed, but whose pen especially against *Galen* yeeldeth too much gall, in his booke *de somno et vigilia*, and in his Commentaries in *artem medicinalem* auoucheth, that there is but one spirit and that Vitall, neither will hee be brought to admit any Animall spirit at all. And first as his custome is, he inueigheth bitterly against his Maister *Galen* accusing him sometimes of leuity and inconstancy, sometimes of ignorance. Of inconstancy in his assignation of the matter and the place of the generation of the Animall spirit. In the matter, because sometimes he writeth that it is made of the ayre we breathe in, sometimes of the vitall spirits, sometimes of blood. In the place of generation, because hee assigneth it sometimes to bee generated in the Textures or complications of the Braine, sometimes in the forward ventricles, sometimes in the backward, sometimes that it is contained in the body and substance of the braine.

Argenterius accuseth *Galen* of inconstancy.

He vnderstandeth not *Galen*'s meaning.

But *Argenterius* his wit was too nimble to fasten vpon the depth of *Galen*'s iudgement, which if he had well attended he should not haue found repugnancy in him. For the most remote matter of the Animall spirit is blood, the neerer matter is vitall spirit, the neere of all is ayre inspired or breathed through the *mammillary* processes, and conueighed not into the textures but into the vpper ventricles. And as the matter, so also the place of their generation is manifold; for they are prepared in the Textures and vpper ventricles, boyled in the third and perfitted in the fourth or in the substance of the braine. Finally, they are diffused into the nerues, and from them conueighed into the body.

Galen accused of ignorance.

He accuseth *Galen* of ignorance, because from the *Net-like texture* he gathereth that there is an Animall spirit, because sayeth *Argenterius*, neither is the Texture conspicuous in a man, neyther is there alwayes required a complication of vessels where there is any spirit generated. For in the heart where the vitall spirit is abundantly generated there is no such admirable web of vessels.

But defended.

But *Argenterius* was so headily transported with a desire of contradiction, that hee did not obserue the tenor of *Galen*'s Argument; for he neuer concludeth that therefore there is an Animall spirit because in the braine the vessels are intangled and interbrayded one with another, but hee saith that this spirit is irrigated or watered and nourished by that which

that

that Net-like web supplyeth vnto it as we haue read in the 5. chapter of the 12. booke of his Method, and in his 7. booke *de placitis. Hip. et Plat.* and the third chapter. But let vs yeelde that *Galen* meant as *Argenterius* vnderstandeth him: shall wee therefore conclude that hee hath written absurdly? Nature is not wont to create any such texture vlesse it be for a new elaboration, but in the braine there appeareth a notable texture which we call *Choroïdes*, therefore in the braine there is preparation of a new spirit. *Argenterius* will obiect that in the left ventricle of the heart the vitall spirit is generated, and yet in the heart there is no complication of vessels.

Obiection.

We answer, that such Labiryntes were not necessary in the heart, because the necessity of the vitall spirit is greater then that of the Animall. And therefore there is a greater proportion of them required then can be confected in so narrow vessels. For the Animall functions are not perpetuall, and beside when a man sleepest they are also at rest. But for the vitall, the soulder we sleepest the stronger they are.

Answer.

Furthermore, all the parts of the creature haue not sence, as bones, gristles, and ligaments, yet all of them do liue. Wherefore because there is a greater exhaustion of vitall spirits their restauration must be *abrupt*, that is, sudden and plentifull. Adde hereto that the vitall spirit doth not onely serue for the accomplishment of the vitall function, but also is the matter of the Animall spirits: and therefore it is necessary that their generation should be in greates abundance, which cannot be accomplished in small Arteries and narrow cauities. Finally, the heart which is the hottest of all the bowels doth suddenly boyle & generate spirits albeit there be not so precise a contaction of all the parts; which thing the braine being far colder cannot performe, and therefore in the brain there was greates vse and necessity of complications of vessels and not in the heart. *Argenterius* proceedeth to goade *Galen* farther. Why are the Animall spirits generated in the complications of the Arteries of the brain, seeing the Arteries of the brain do not differ in kind from the arteries of the other parts of the body? Now in the other parts the arteries do not generate Animall spirits; therefore they shall not do it in the brain. I answer, that the Animal spirit doth not attain his forme & difference in the complications, but eyther in the ventricles or in the substance of the brain. In those straights and narrow passages it is only prepared, and attaineth a kind of rudiment or initiation by irradiation from the braine. So in the crooked rings of the preparing vessels the seed hath a delineation from an influence of the testicles. In the mesaraicks the blood is prepared by a vertue beaming from the Liuer: neyther did *Galen* euer acknowledge any other vse of those complications then the attenuation of the vitall spirit and the preparation of the animall.

Obiection.

Answer.

Fourthly, that there is no animall spirit he thus proueth. If in the brain a spirit were contained, then our sensation and cogitations should be perpetual, because the faculties of the soule are euer prest and at hand. I answer that the soule doth not alwayes worke though it haue an Organ; because the Organ is often hindred, as when the naturall heate is drawne inward, for example in sleepest. Again, there is not alwayes a sufficient supply of Animall spirits, and thence it is that the functions doe not alwayes worke, but sometimes rest themselves as in the night, in which time the spirits are redintegrated and refreshed; and this according to Physicians is the onely final cause of sleepest or rest. Fifthly, he obiecteth that though it should be granted that there is an Animall spirit, yet it cannot descend to the feete because it is of a fiery and airy Nature. But this argument is already answered thus: That all the spirits by their proper motion are carryed vpward and outward: but when they are directed by the soule they are diffused and dispersed into all the parts of the body. So the Arme being naturally heavy, is often times depressed by his Elementary forme, yet it is lifted vp againe by the soule; for our naturall heate is by diffusion communicated to all the parts. Sixtly, if there be more kindes of spirits, then (saith *Argenterius*) it will follow that they must be mingled and confounded, which confusion of the spirit, will also enduee eyther a confusion or nullity of the actions. But let vs grant (which yet is not true) that the spirits are confounded, will it thence follow that euery spirit shall not performe his owne office? Why may not the vitall do the offices of life and the Animall supply sence and motion? For these spirits are not contrary, that in the permission they should abate their power and force mutually. Seuenthly, he sayth, that the pupilla or apple of the eye is dilated by the spirit of the arteries which is vitall and not Animall. On the contrary, we thinke that when one eye is closed vp the apple of the other cannot in a moment be dilated by any spirits proceeding from the arteries, because the arteries of bothe eyes doe not meete and vnite themselves as do the optick nerues.

Argenterius. Argument. Answer.

The first answered.

The sixth

answered

The seventh

But there is a great distance betwixt them, and so great as that it is impossible that the Viual spirit together with the arteriall blood should so instantly moue it selfe from one eye to another.

The eight.

Eightly, hee objecteth that the influence of an Animall spirit is not necessarie, a quality onely or beaming light might be sufficient, for nothing that is corporall is moued in an instant. But we know that the Muscles obey the Brain according as our will commandeth them, for we are able in the twinkling of an eye to moue our vtmost ioynts. We answer that the spirit which is the Organ of the soule dooth instantly accomplish the commandement thereof and is euer adrest in the Nerues, and as it is spent repayed by new influence and succession; whence it is that before the exhaustion or expence of the olde a newe is ministrd to supply the roome. Which *Lucretius* in an elegant Verse hath thus chanted:

Answerd.

Ergo Animus cum sese ita commouet ut velit ire

Inque gredi, fert extemplo qua in corpore toto

Per membra atque artus animali dissita vis est:

Et facile est factu, quoniam coniuincta tenetur.

When the Soule listeth herselfe to disport,

The powers throughout the body disioyned,

Into the Ioynts and Members resort,

For the Soule holdeth them alwayes conioyned.

Argenterius
conclusion.

Finally, he concludeth that there is but one influent spirit because there is but one soule, one influent heat, one nourishment of the parts, to wit, the blood and one aire that is inspired. These are *Argenterius* Darts which he casteth against *Galen*, which how light they are and little sa- uouring of Physicke let the learned iudge. True it is that the soule is but one, but that one is furnished with diuers Faculties: there is but one Aliment, but by diuers concoction it recey- ueth a diuers forme, and that one according vnto the diuers substance of the parts is of di- uers sorts.

Our conclu-
sion.

As therefore there are three Faculties of the Soule, the Naturall, Vitall and Animall; three principles, the Braine, the Heart, and the Liuer; three Organs ministring vnto them, Veines, Arteries & Nerues: so are we to thinke that there are three spirites distinct in forme & kind, otherwise all thinges should be one because the common matter of all is one and the same.

Other reasons
to proue there
is no Animall
spirit.

There be other weapons farre keener then those of *Argenterius*, wherewith we may affront the opinion of *Galen* concerning the Animall spirit, which for disputation sake and that the truth may be better cleared we will thus vrge. Whatsoeuer spirit is contained in the Cavity of the Arteries is to bee accounted Vitall. But all the spirits contained in the Braine are included within the Arteries, neyther doe they euer yssue out of them, and therefore the spirits of the Braine are Vitall and not Animall.

The first.

The Minor proposition or assumption is thus confirmed. If the spirits boult out of the Arteries then are they conueyed either into the Ventricles or into the substance of the Braine, when if we admit, then will the spirit become presently condensed. For the scalding Vapors which arise into the Braine from the bowels boyling with extraordinarie heate are much thinner then the spirits and yet are instantly condensed or thickned.

The answer.

Now that the Vapor is thinner then the spirit may be prooued, because the vapour exha- leth outward, the spirits remaining within. To this argument we answer, that the Nature of Spirits and Vapors is diuers. The spirits are retained by the Soule, because they are familiar and as it were of Kin vnto her, but the Vapors are strangers or rather Enemies, and therefore they exhale and are condensed or thickned.

Another Reason.

The second.

If the Spirits of the braine do forsake the Arteries and be transfused into the Ventricles, seeing in the third Ventricle there are two passages, one forward and another backward, why doe they rather passe backward then forward? whereby shall it be conducted after it fall out of the Arteries so that it moue in a right line, and that without any violence but with an easie and gentle motion into the fourth Ventricle. I answer, that it is the Soule that direct- eth the Instruments of the soul, and that it is diffused into this part rather then into the other, because it is the Soules good pleasure so to command.

The third.

Answerd.

Thirdly, it seemeth not consonant to reason that a Spirit should be generated and contay- ned in the Ventricles of the Braine, because those Ventricles were ordained for the expurga- tion of superfluities. I answer, that Nature vseth one part for diuers vses, for as the Nose was primarily created for smelling and the inspiration of ayre, & secondarily for the expurgation of

of the Braine; so it may bee the forward ventricles of the braine were primarily made for the preparation of the spirits, and secondarily to auoide excrements.

Fourthly, that whereas one eye being shut, the apple of the other is dilated: It argueth that the spirits are not transported by the nerues but by the Arteries. For the optick nerues do not touch the apple of the eye, yea betwixt them are interposed many bodies and those very thicke, to wit, the Christalline and the Watrish humors, through which the spirits in such a moment cannot passe. For if it cannot passe through a drop of phlegme in the oppilation or stopping of the optick, which maketh the disease we call *Gutta serena*; how shall it passe the thicknesse of the Christalline humor? The spirit therefore yssueth through the small Arteries, which together with the *grape-like* coate are continued to the *Pupilla*. This reason would urge very much vnlesse Anatomy did teach vs that the opticke nerue when it cometh vnto the Christalline humor doth not there determine but is diffused and amplified into that coate which is called *Reticularis* or the Net. Now the *Net-like* coate passeth euen vnto the apple.

Finally, that there is no Animall spirit may thus be demonstrated. The spirits are those that do conueigh and transport all the faculties, and serue onely for that vse. Now there is no Animall faculty transported from the braine into the body, and therefore there is no Animall spirit. That the Animall faculty is not transported from the braine into the body may thus be prooued.

A faculty is a propriety of the soule, now euery propriety is inseparable from that thing whereof it is a propriety. Wherefore wherefoeuer the soule is, there also shall his faculties be. But we know that the soule is *Tota in toto et tota in qualibet parte*, that is, wholly in the whole and wholly in euery part. Whence it will follow, that the faculty is not onely in the braine but also in euery part of the body, and that as absolute and perfect as it is in the braine it selfe, because the whole soule is absolute and perfect in the least part.

The Philosopher makes answere, that the essence of the soule furnished with all her faculties is indeed euery where; but doth not worke euery where because euery where it hath not Organs. For the Soule doth not moue neyther partaketh all sense without the Animall spirit, as it seeth not without an eye.

We conclude therefore that there is an Animall spirit which receiueh an inchoation in the Textures, an elaboration in the ventricles, and a perfection in the substance of the braine, where also it is the vehicle of the principall faculties, and passing into the spinall marrow and the nerues is the immediate Organ of sense and motion.

QVST. IX.

Whether the braine be moued by a proper & In-bred faculty;
or by the motion of the Arteries.

IT is a very hard and difficult question whether the brain be moued by a proper and ingenit power of his owne, or by some outward violence. That the braine is moued no man in his right wits will deny vnlesse he be vtterly ignorant of Anatomy. For in great wounds of the head wherein the Scull is broken and the membranes are detected, there is a manifest motion to be seene. Againe, in children new borne the forepart which we call the mould of the head doth so conspicuously pant and beate, that the very bones of the Scull which at that time are exceeding soft are moued therewith.

But because among the Philosophers there is a threefold kinde of motion, the first naturall, the second Animall, and the third violent: It is a great question to which of these kindes the motion of the braine is to be referred. It seemeth to some that the braine cannot be the originall of the Animall motion vnlesse it selfe be moued voluntarily; for it were absurd to say that there yssued from the braine into the whole body a power or faculty which doth not reside therein as in the fountaine and originall.

But this opinion hauing no strength of argument to support it, hath also beene little ventilated by the Philistions. For an Animall motion is *proaireticall*, or with choice being intended, remitted or intermitted according to the arbitrement of our will. Now we know that the braine is not moued at our dispose, but according to it owne instinct, and therefore the motion thereof is not voluntary.

No man will say that it is violent; for *Aristotle* in his second booke *De ortu* opposeth that which is violent to that which is according to nature. It remaineth therefore that it is naturall,

The fourth

ued voluntari-
ly.Disproued
That it is not
violent

rall. By naturall I vnderstand not that which is only directed by Nature, but whatsoeuer is not voluntary although it be gouerned by the soule.

Now whether this motion be of the whole braine or onely of the partes, or whether it be moued by an in-bred faculty ora power from without, that is, from the Arteries and the spirits, it is greatly controuerted. *Galen* in the second chapter of his fourth booke *de differentijs pulsuum* saith, that some thinke that the membranes onely do beate, others onely the body of the braine, others both the membranes and the braine it selfe. Some are of opinion that the Animall spirits onely are moued not the body of the braine, which they illustrate by the example of a *Vertigo* or giddinesse wherein all things seeme to runne round, because of an inordinate and Turbulent motion of the spirits. The vulgar opinion is that the braine is not moued by any proper motion of it owne, but by a motion from without, that is to say, from the Arteries. Neither do his ventricles breathe in aer, (as *Galen* would haue it) neyther are they distended and contracted.

The first opinion.

That the braine is moued according to the motion of the arteries Reason 1.

The reasons of this are: first it doth no more becomene a principle of motion to bee moued, then it becommeth a principle of sense it selfe to haue sense, because as *Aristotle* saith, euery instrument of sense must be destitute or void of all the objects of that sense whereof it is an instrument: now the body of the braine hath not sense and therefore it hath no motion.

Furthermore, if the braine doe breathe by a proper power, it would follow that because the substance thereof is soft, and the membranes that compass the ventricles very fine & thinne, it followeth I say, that that membrane must in the dilatation and contraction be violently torne asunder.

Thirdly, the third and fourth ventricles of the braine commonly so called, are of the same substance and temper that the vpper ventricles are of; for the vse of them all are one and the same; but it is granted that the latter ventricles doe not Respire, and therefore neyther shall the former be dilated or contracted.

They vrge further and thinke that this weapon hath a keener edge. In grieuous wounds of the head when the braine is vncovered, the motion of the braine and the arteries doeth not appeare to differ at all, but as one Pulse is answerable to another, so likewise the motion of the braine and the arteries doe accord. Now if the braine did beate by an in-bred power, then must it needes be that sometime the braine and the arteries should not beate alike and at the same instant.

Finally, there is no Attraction, no Expulsion without the helpe of fibres: so the heart hath his fibres, as also the stomacke, the guttes, the veines and the arteries; but in the braine there appeare no fibres at all; Ergo the Motion of the *Diastole* and *Systole* of the braine is not proper and peculiar vnto his substance.

Verily these reasons are so strong that the time hath bin (saith *Lauré*.) when I was conuinced by them and constrained to subscribe vnto this opinion; but looking ouer with a little more diligence the works of *Galen* and considering some passages in his Booke *de Odoratus Organorum*, *de vsu partium*, *de Placitis Hippoc. & Platonis*, with better deliberation, at length I altered my minde, and am now resolu'd that the body of the braine doeth respire by a proper faculty and in-bred Motion.

That the braine doth respire by it owne force.

The authority of *Galen*. Reason 1.

Let vs heare *Galen* disputing in expresse words in the last Chapter of his Booke *de Odoratus Organorum*, Nature, saith he, hath not denyed motion to the braine whereby it might draw Ayre for his refrigeration and retorne the same backe againe for the expurgation of superfluities. Again in the 4th Chapter of the same Booke, It is not impossible that the braine should yeeld vnto it selfe a kinde of Motion (though it be but small) sometimes into it selfe, sometimes out of it selfe, so that it should be lesse when it contracteth it selfe, and more spread when the parts of it are dilated. Thus saith *Galen*.

But it shall behooue vs to establish his authority by reason also and waight of argument. It is most certaine that the Animall spirit is generated first in the vpper ventricles of the braine, which spirit being of it owne Nature ayrie and hot, stood neede of the Inspiration of ayre which was familiar and of kin vnto it, as well for his nourishment as that by it it might be refrigerated: wherefore when we draw our breath inward, the ayre also is drawne into the braine, and when we breath outward, a fumid or smoaky vapour (which is the excrement of the Animall spirit) is thrust out and auoyded.

Hippocrates.

This *Hippocrates* elegantly expressed in his Booke *de morbo sacro* or of the Falling sicknesse. When (saith he) a man drawes in ayre by his mouth & his nose is shut, first of all the breath commeth

to the braine. Now this Inspiration of the ayre into the vpper ventricles of the braine and the Expiration of the same is not made by arteries, but by certaine protuberations or swelling productions of the braine much like the Nipples of a womans Pap, which also are the Organs of smelling. The Motion therefore of the braine which is accomplished by inspiration and Expiration proceedeth from the braine it selfe not from the arteries. Againc, that the ayre is drawne in by these productions may thus be proued.

The ayre and odours doe passe by one and the same way, for no smell can be felt although it be driven violently into the nose vnlesse therewith ayre be drawne in, now odors do passe into the braine by those productions before named, not by Arteries: and therefore by the same productions ayre is inspirated and transported into the forward ventricles.

Furthermore, if the braine do beate by the Arteries and not by an in-bred power for the generation of spirits; why then is not the spinall marrow also moued? You will say haply, that in the marrow of the backe there is not so great plenty of Arteries as are found in the braine it selfe. I answer, it may well be, for there is not the same quantity of matter or substance in the braine and the marrow. But if you compare both bodies together, then will the proportion of the Arteries be as great which runne through the membranes inuesting the marrow. Wherefore the spinall marrow is not therefore immoueable because it wanteth arteries, but because in it there is no generation of vitall spirits as there is in the Braine.

The third argument is on this manner. There is a certaine distance betwixt the body of the braine and the *Dura meninx*; not to giue way to the *Systole* and *Diastole* of the Arteries, for they are not so lifted vp; nor to auoid danger, because the *Pia mater* or thinne membrane is interposed betweene them: the distance therefore is left for the motion of the braine, and so we see that in the heart there is a distance betwixt it and the *pericardium*, least if they had touched one another the motion might haue beene interrupted.

Fourthly, how is it possible that so great a waight and masse of moysture, as the braine is, should bee dilated by a few small arteries? (for so I worthily call them that are sprinckled through the body of the Braine) seeing that the large and notable Arteries of the spleene are not able to moue his rare and smal body? I answer, Anatomy teacheth vs that this bowell is wouen with infinite Arteries, and yet no man euer saide that the spleene was moued vnlesse it be in a tumor or inflammation, and then any part will be moued.

Fiftly, if the motion of the braine be the motion of the Arteries and not of the marrowy substance, then it was ridiculous to say that the braine is moued because the Arteries are onely moued. For so we might say that the stomach, the guts and the spleene were moued because the Arteries do beate euery where. And therefore if we imagine that the marrow of the braine is distended by the *Diastole* of the Arteries, why should we not beleue also that all the rest of the parts of the body do beate, because they haue all proportionably as many Arteries?

Finally, the proceffe called *vermi-formis*, the *Conarion* and the buttocks of the braine doe shew that there is a peculiar morion of the braine which differeth from the motion of the Arteries. For the wormy proceffe being made shorter, openeth the way which is from the third vnto the fourth ventricle, and whilst the same proceffe is extended it shutteth the passage againe least the spirit should returne into the vpper ventricles: so that it seemeth there is the same vse thereof that there is of the valves placed at the mouth of the great Artery: now the opening and shutting of this clift proceedeth not from the Arteries, but from an in-bred power of the braine it selfe. It is therefore more probable to thinke with *Galen* that the braine is moued by a naturall motion and that proper to it selfe for the nutrition of Animall spirits, the tempering of them and their expurgation.

The reason and nature of this motion is on this manner. When the braine enlargeth it selfe it draweth ayre out of the nostrils by the mammillary processes and spirits out of the Textures or complications of the small Arteries. This ayre and those spirits it mingleth in that rest or *interim* which is betweene the two motions: but when in the *Systole* it contracteth it selfe the sides falling together, the inward ventricles are straightned and the Animall spirits powred out of the foremost into the hinder ventricles.

But here ariseth a scruple of no little moment, which is, whether the ayre is deriued to the braine when it is distended or when it is contracted? It should seeme that the ayre is drawn in in the contraction, because when the braine is contracted it departeth a little from the Scull: the Scull because it is immoueable doth not follow the contraction of the braine.

Reason 2.

Reason 3.

Reason 4.

Reason 5.

Reason 6.

The Conclusion.

The reason of the motion of the braine.

A great question.

It is therefore necessary that there must be a vacuitie betweene the braine and the Scull, or else there must be aire drawne in, wherewith the place must be filled.

What we
thinke.

But wee thinke that the aire is drawne into the dilatation of the braine, neither doe wee allow that there is any empiric place left in the contraction, because in the contraction there is an expression of aire and fumed vapours through the sutures. Now let vs giue answer to that which is objected against this our opinion.

The reason of
the contrary
opinions are
answered.
To the first.

They objected first. That the braine is the beginning of motion, and therefore ought not to be moued. We answer, That indeed it must not be moued with the same Motion wherewith it moueth the partes: It giueth to the partes of the body voluntary Motion, but it selfe is moued with a naturall Motion. The braine is moued after the same manner that it hath sense: Now the sense of it is naturall as is the sense of bones or the bowels, whereby it being prouoked, auoydeth that which is offensiu vnto it, as we may see in sneezing and in the falling sicknesse. It is moued for the generation of animall spirits.

To the se-
cond.

Their second argument was, that the ventricles of the braine did not respire, because in that perpetuall distension the thin Membrane of the braine would haue bin broken: But they do not remember that in sneezing and in the Epilepsie, the contraction of the Braine is more violent then the ordinary Motion; and yet in neyther of those is the Membrane broken. In Sternutation or sneezing, the Braine collecteth it selfe and is contracted, the better to exclude that which is offensiu vnto it. For the same that the cough is in the chest, and the hickocke in the stomach, the same is sneezing in the Braine. In the Epilepsie the whole Braine is contracted and corrugated.

To the third.

Thirdly, they obtrude vnto vs: that the backward ventricles do not respire, and therefore that the forward ventricles do not dilate or contract themselues. I answer, first that I know not by what flight or art they can perceiue that the backward ventricles do not moue. But let vs grant that they do not, yet is their consequence not good, for the formost ventricles doe stand in neede of more, at least of more conspicuous Motion then the other, because in the formost the spirit is prepared and purged, in the backward they are contracted when they are pure, sincere and already purged.

To the fourth

Fourthly, the motion of the braine and the arteries doth not appeare to be vnlike one the other. I answer, that they are not indeede vnlike, because their vse is the same, there is the same finall cause of generation of the spirits and of their expurgation.

To the fifth.

Fifthly, they doe not thinke it is moued with any proper motion, because there appeare in the braine no fibres at all. We answer, that the bones doe draw their nourishment, & expell that which is superfluous without the helpe of Fibres. Lastly, there is not the same reason or nature of the heart and of the Braine: for the Heart stood neede of Fibres not for the traction and expulsion of aire but of blood. In the *Diastole* the Heart draweth blood by the right Fibres, and the same blood it expelleth in the *Systole* by the transuerse. But the Braine when it is moued draweth aire with most thinne vitall spirits for the traction whereof there is no neede of the helpe of Fibres. Hence we thinke it is sufficiently manifest, that the Braine is moued by an in-bred facultie, and not onely by the motion of the arteries.

To the last.

Q V E S T. X.

Whether the Braine hath any sense.

That the
braine hath
sense.
The authori-
ty of Hippo-
crates.
Of Galen.

IT is a notable Controuersie amongst Physitians, whether the Brain haue any sense or no. That it hath sense it may bee demonstrated by authoritie, experience and reason. *Hippocrates* in his Booke *De vulneribus capitis*, resolueth that it hath sense where he saith, *That the braine above the finciput doth soonest and especially feele any inconuenience that is either in the flesh or in the bone.* *Galen* in his booke *De plenitudine*. The Braine (saith he) and the spinall marrow are accounted amongst those things which haue sense. And if in a frensie no paine bee felt, it is because the minde is disquieted. Againe in his booke *De Odoratus organo* he attributeth to the braine manifest sense. Moreouer experience and sense do confirme the same. *Galen* in the 4. chapter of the aforesaid booke, telleth a storie of a certaine man whom hee commanded to snuffe vp into his nose, and to receiue at his mouth *Nigella*, Githor Pepperwort finely beaten and mingled with old oyle, who thereupon felt a great gnawing in his braine. Which (saith he)

Experience.

Reason.

is a manifest argument that some of that *Nigella* went into the ventricles of the Braine, and cleaving to the *Pia mater* or thin Membrane, or else haply in the Braine it selfe, was the cause of that paine.

Again, reason seemeth to perswade the same. The Braine is the fountaine and originall of all sense, and therefore it selfe must need be sensible; because by it all other parts haue sense. For it is an axiome in Logicke, *Propter quod unumquodque est tale, & illud magis tale. That for which any thing is such or such, must needs it selfe be more such or such.* Furthermore, vnlesse the Braine haue sense, it could not rouse it selfe vp to the expulsion of that which is offensive: for in steruations or sneezings, and fits of the Epilepsie or falling sicknes, how should the Brain be moued and shaken to exclude and auoyde the humour or vapour by which it is vellicated or goaded vnlesse it felt the affluence thereof.

Contrarily, the opinion of those who determine that the Braine hath no sense, may also be confirmed by authoritie, experience and reason. *Aristotle* in the 17. chapter of his 3 booke *De historia Animalium*; And in the 7. chapter of his second booke *de partibus Animal*: writeth, that the Braine & the marrow haue not *sensum tactus* the sense of feeling. *Galen* in the 8. chapter of his first booke *De causis sympto*. The Braine (saith he) was ordained by nature, not to haue sense but to communicate the faculty of sensation to the instruments of the sense. In his third booke *De causis sympt*: hee calleth the Braine an Organe without sense.

Experience (then which nothing is more certain) conuinceth the truth of this position. For when the Braine is wounded the patient doth not feele although the substance thereof be pressed with a sharpe probe, ne nor if some of it be taken away, which thing is ordinary for Physicians and Chyrurgions to obserue.

Finally, it may be demonstrated by reasons. Euery Organ (saith the Philosopher) must be that is, without any extermall quality. So in the Christalline humor of the eye there is no colour, in the eare no sound, in the tongue no sauour; and the skin which is the Iudge of those qualities which moue the sense of touching, is it selfe of a moderate temper. So the braine is the seate of the common sense and iudgeth of all sensation, and therefore must it selfe be without sense.

Moreouer, the braine ought not to be sensible, for if it were hauing his scituation vppermost, and (like a cupping glasse) drawing and supping vppe the exhalations of the lower parts it would by their affluence perpetually be payned.

Finally, the substance well nigh of all the bowels is insensible, as of the liuer the spleene, the lungs, &c. and therefore the substance also of the braine is insensible.

To this opinion we rather subscribe then to the former, following therein *Galen* in his first booke *de causis Symp*: where he is not of opinion that the braine hath sense, but onely that it can discerne the differences of sensible things.

Those things which are brought to proue the contrary assertion, seeme to me to be very light. *Hippocrates* sayde that the braine did feele those iniuries that were in the flesh and in the bone, that is to say, it is affected and altered by them. So the same *Hippocrates* saith in his Aphorismes that the bones do feele the power of cold, that is, they are altered by cold. Wherefore he vseth y word Sense in that place abusiuely. *Galen* attributeth sense to the braine. It is true, yet not to his marrowy substance which is the fountaine and originall of all the Animall faculties, but to the *Pia mater* or thin membrane which insinuateth it selfe deeply into the conuolutions thereof. As for that logicall Axiome, it is only true in these causes which we call Homogeny, and those also conioyned. For the Sunne being of it selfe not hot, yet heateth all sublunary things. And whereas they say that the braine is shaken in the exclusion of that which is hurtfull, and thence would proue that it is sensible; we answer, that there is seated in euery particullar part a naturall power to expell that which is hurtfull; which power is sometime ioyned with Animall sense, sometimes also it is without the same. So the bones haue a power of excretion, and the flesh almost of all the bowles being insensible, is yet apprehensue of those things that are hurtfull, yea to expell them also and driue them forth. There are in the nature of things certaine *Sympathies* and *Antipathies*.

Fernelius in the tenth Chapter of the 5. booke of his *Physiologia* hath deuised a new and vncouth opinion concerning the motion and sense of the braine: He conceiueth that all motion is from the marrow of the braine, and all sense (saith he) floweth from the Meninges or Membranes: because the body of the braine is perpetually moued, and yet hath no sense at all; on the other side the membranes that incompasse it are of themselves immouable, especially the *Dura mater*, and yet their sense is most exquisite. So in the discase

The contrary opinion.
Aristotle
Galen.

Experience.

Reasons.

Answers to the Arguments of the former opinion.

How the braine apprehendeth that which is hurtfull.

Fernelius new opinion.

ease which wee call *Delirium*, that is, an aberration of the minde, and in the Letargy which are affects of the Braine there is no paine at all: but if a sharpe humor or vapour be transported into the Membranes, then is the patient as it were on the racke.

Furthermore, the spine and all the nerues haue their marrow from the braine and the same inuicted with membranes: all which haue the same power and nature which they receaued from their originall. Therefore the fore-part of the braine is the originall of sense, the back-part the beginning of motion, and the meninges or membranes are the beginning of touching. Those nerues that are fullest of marrow are the instruments of motion, but those are the instruments of touching which are for the most part deriued from the meninges.

Fernelius his
first error.

These are *Fernelius* words, wherein, saith my Author, by the fauer of so great a man, I find some things that cannot be warranted. First, he saith that all voluntary motion floweth from the Marrow because the Marrow is perpetually moued, as if the motion of the Braine and of the Nerues and Muscles were alike. The motion of the Braine is Naturall consisting of a *Diastole*, a double rest and a *Systole* for the generation of Animall spirits, but the motion of the Muscles and the Nerues is voluntary.

Second.

Furthermore, we are not to thinke that the Nerues are so much the fitter for motion by how much they haue more marrow; rather we beleue the contrary, that the harder Nerues are fitter for motion and the softer for sense, because sensation is a passion but motion an action; we know also by experience that the Opticke Nerue which is the softest of all the Nerues hath more Marrowy substance then the Nerue of the second Coniugation, yet the Opticke is the Nerue of Sense, the other the Nerue of Motion.

The authority
of *Galen*.

Add heereto, that Motion should bee rather ascribed to the Membranes then to the Marrow, because the Marrow melteth away, but the Membrane is stretched and contracted: so the Nerues of children are weake and soft and vnfit for motion. To all these let vs add the authority of *Galen* in the the third chap. of his second Booke *de Placitis Hip. & Platonis*, where he saith, that the faculties of Motion and Sense are only contained in the Marrow of the Braine & that the Membranes were made to cloath & nourish the Marrow & for no other vse.

The Braine
hath neyther
sense nor mo-
tion, and yet
is the originall
of both.

We conceiue therefore that this Paradox although it be witty, it will not holde at the Touchstone, and therefore we determine that the Marrow of the Braine is without all sense and Animall motion, and yet is the fountaine and originall of all Animall Sense, and motion. Of Sense, because it perceiueth the representations and receyueth the impressions of all sensible things. Of Motion, because it dispenseth and affoordeth all that power and command for the auoyding of that which is noxious, and prosecution of thar which is profitable; from whence it commeth to passe that when the Braine is il affected the inferior parts haue neither Sense nor Motion.

QUEST. XI.

Of the Temperament of the Braine.

Reconciliation
of *Aristotle* &
Galen.

THE Physitians and the *Peripatetikes* in this do agree, that the braine in the Actiue qualities is cold, in the Passiue moyft. But herein they differ, that *Aristotle* in the seventh Chapter of his second booke *De partib. Animalium* and in the fifth Chapter of his booke *De Somno & Vigilia*, determines that the braine is actually cold and ordained to refrigerate or coole the heart. Contrariwise, the Physitians say that it is Actually hot. For *Galen* in his eight booke *De Placitis Hip. & Platonis* saith, the brain is hotter then the most fowltry aer in summer. Some there are that do thus reconcile *Galen* and *Aristotle*; There is (say they) a double temperament of the braine, the one In-bred, the other Influent: by the In-bred temper, the proper composition and the marrowy substance, the braine is very cold; but by the influent temper it is hot, for it is full of spirits and intertexted with very many small Arteries.

If you respect the in-bred temper, then is the temperament of the braine and the spinall marrow one and the same, because they haue the same marrowy substance. If you respect the Influent temper, then saith *Galen* in the ninth chapter of his second booke *De Temperam.* the braine is hotter then the spinall marrow, as well because there passe vnto it more Arteries, as also because many fumid exhalations do ascend vnto it. Some say, that the braine is simply and absolutely hot; but colde comparatiuely, because it is the coldest of all the bowels. And *Galen* in *Arte medica* writeth, That a hot braine is colder then the coldest heate. In which respect *Hippocrates* in his booke *de Glandulis* calleth the

the braine *μῆλον τοῦ θυμῶν* the *Seate of Coldnesse*. But I cannot approve this opinion. For if the braine be colder then the skinn which is in a meane betwixt the extremes, then it is simply cold and not hot. Now that it is colder then the skinn *Galen* teacheth in his second booke *de Temperamentis*.

It will bee objected, that if the braine bee laide bare it will presently bee refrigerated by the aer, whereas the skinn is not affected therewith. I answer, that the braine is altered by the aer, because it is not accustomed thereto as the skinn is; so the Teeth because they are accustomed to the aire doe not grow blacke as other bones do if they bee layde bare. Or againe, that the braine is hotter to feele to then the skinn, because it is covered with the scull and the membrane and hath many complications of arteries therein. We determine therefore that the Braine of his in-bred temper is colder then the skin, but by his influent temper is hotter. That the Braine should be colde it was very necessary, least a Member set apart for continuall cogitation or discourse should bee enflamed and set on fire. Againe, that the animall spirits which are very fine and subtil might bee retained and not vanish away. Finally, that our Motions and sensations should not be rash or phanaticall as they are in such as are phreneticall, that is, haue their braines inflamed. It may be objected, if the Braine be cold, how then doth it ingender animal and attenuate vitall spirits; for these are the workes of a vehement heate? I answer, that the spirits are attenuated in the textures of the small arteries, and in the strayghtes of those passages: and that the animall spirit is framed not so much by any manifest qualitie such as is heate, as by an in-bred and hidden proprietie.

Objection.

Solution.

Why the
braine ought
to be cold.Objection.
Solutions

But the reason why the spirits of the extreame hote Heart are thicker then those of the very cold Braine must not be referred to the weakenesse of the heate which is the worker, but to the disposition of the matter which is the sufferer. For the heart maketh vitall spirits of thicke blood brought vnto it through the hollow veine: the Braine maketh Animall spirits of subtil and thinne vitall blood and spirits: so a weaker heate boyleth a thinne and easily concocted aliment, whereas a very strong heate will hardly overcome a thicke aliment. It remaineth therefore that in the active qualities the braine is cold.

Why the spi-
rits of the ex-
treame hot
heart are thicke
then the
Animall spi-
rits.

That in the passive qualities it is moyst both by the in-bred and influent temper no man I thinke is vnresolved: for it appeareth euen to the touch. Now it was by nature created moyst, as well for more perfect sensation, (for sensation is a passion; and those things that are moyst do more easily receiue the images and representations of things offered vnto them) as also for the originall and propagation of the nerues which would not haue beene so flexible if the braine had beene hard. Adde heereto that if the braine had beene hard it had also beene heavy and the waight and hardnesse thereof would haue beene offensive to the sinewes.

Why the
braine was
made moist.

Finally, it was made moyst least being a member destined to perpetuall motion sensation and cogitation, it should haue beene inflamed if the moysture had not beene an impediment thereto. But if you compare the two qualities together then we say that the braine is more moyst then cold: for amongst the moyst parts it hath a third place, amongst the cold parts almost the last.

QUEST. XII.

How many and what are the Excrements of the Braine, and by what wayes they are purged.

THE Braine being of a medullous or marrowey substance and by his naturall temper cold and moyst because it is nourished with flegmaticke blood, heapeth together abondance of excrements.

Why the
braine aboundeth
with ex-
crements.

Moreover, being as it were the Chimney of the whole body, or the head of a Still (whose figure also it representeth) it sucketh and draweth from the lower part, all kinds of expirations as *Hippocrates* teacheth in his Booke *de Glandulis* wherevpon it becommeth filled with vapors and as it were drunke with their continuall affluence and so stableth in it selfe a masse of superfluity; so that it aboundeth with excrements as well of it selfe, that is, of it own nature because it is cold and moyst, as also by euent for that it is seated in the vppermost place whither all vapors doe resort.

These

Thicke.

Thinne.

These excrements of the braine, if wee beleue *Hippocrates* and *Galen* are of two sorts, some are thinne and some are thicke; the thinne like vapour or soote doe expire or exhale vpward by insensible passages; the thicke are purged downward by open and conspicuous wayes. With the thinne and vaporious exhalations the braine is cloyed onely by reason of his situation, for all fumes doe arise vpward; and beside all vessels doe determine in the head. But it aboundeth with these crasse and thicke excrements about other bowelles by reason of the cold and moyst temper thereof.

The kinds of thicke excrements.

Of these thicke excrements some are phlegmaticke, waterish and ferous; some are bilious, some melancholy. The waterish are generated of the reliques of the phlegmaticke and crude blood: the bilious or melancholy out of the earthy portion of the Aliment torried by the violence of heate, and therefore they grow bitter.

Argenterius his error concerning the phlegmatick excrements of the braine.

Argenterius is of opinion that that waterish and mucous humour which is auoyded partly by the nose partly by the mouth and pallar, is not the proper excrement of the brayne, because many men and women doe seldome or neuer spit, and as seldome auoyd the moisture by the nose; but saith it is a humour ingendred in the liuer, mixed with the blood and contained in the veines, not generated in the braine vpon the concoction of the Aliment, but is thither conueyed from below: and because through the weaknes of the concoction and cold distemper it cannot bee assimilated by the braine, it returneth back againe as a redundancie or superfluitie and is cast out by the mouth and by the nose. Which assertion of his if it were true, what reason had nature to place in the saddle or seate of the wedge-bone that kernelly and spongie flesh? Was it not appoynted to receiue this very excrement? If this phlegmaticke humor were onely generated in an intemperate braine, what vse were there of the glandule which is found in all braines though most temperate? Nature is too wise and prouident so rashly to frame any part where there shall not be continuall vse thereof. In this opinion therefore of *Argenterius* wee can finde no vse either for the *Tunnell* or the *phlegmaticke Glandule* if the braine be not distempered. Moreover, it is not true that he saith, that those whose braines are temperate doe not spit phlegme or auoyde mucous matter by their nose: for *Galen* in the 13. Chap. *Artis parue* teacheth, that in a braine which is most temperate the excrements that are purged by the nose and by the pallate (such as are waterish and mucous excrements) are in moderate quantity: neither are wee to attribute it vnto perfect sanity when we finde those excrements by the passages not to bee auoyded. Wherefore we conclude against *Argenterius* that those phlegmatick and mucous humors are the proper excrements of the braine, because in the braine they haue peculiar conueyances and channels by which they are auoyded, framed by Nature onely for their euacuation.

Confuted.

Having thus determined concerning the differences of the excrements of the braine, let vs now see by what passages euery of these excrements are auoyded.

By what waies the thinne excrements breathe out.

The thinne and fuliginous excrements arising vpward because of their leuitie, doe expire or breathe out through the Meninges, the Skull and the Skin. Through the Meninges and the Skinne not by any sensible or conspicuous way but by insensible exhalation; for their bodies while a man is aliue are infinitely perforated or at least peruious with many small holes. But these sooty vapors because they could not passe the thicknesse and density of the bones, therefore is the Skull distinguished with sutures or seames, so that it consisteth not of one bone but of diuers ioyned together by those sutures, through which as also through the holes which are thrilled betwixt the tables of the Skull these thinne excrements and fuliginous vapors doe exhale.

The waies of the thicke excrements,

Hippocrates.

But the thicker excrements descending dwneward by the Naturall and Elementary forme, haue manifest and conspicuous passages, concerning which Physitions doe not so perfectly agree among themselves; *Hippocrates* in his Booke *de locis in homine* and *de glandulis*, acknowledgeth seauen wayes by which the humour passeth out of the braine, that is through the nose, the eares, the eyes, the pallar, into the throat and gullet through the veines, into the spinall marrow and into the blood.

Galen.

Galen in his 13. Chapter *Artis parue*, saith, there are foure passages, the pallar, the nose, the eares and the eyes. The same also he saith in the third Chapter of his second Booke *de locis affectis*, and in his first Booke *de sanitate tuenda*: but in his Commentary vpon the 21. Aphorisme of the first Section, hee nameth onely the pallate and the nose, as also in the first Chapter of his 9. Booke *de usu partium*, where hee saith, the passages of the braine which bend downward doe send out the thicke excrements as well by the pallate into the mouth

mouth, as also by the body of the Nofethrils, and these passages are large and conspicuous. In his first Booke *de symp. Causis* and the 8. *de usu partium* he saith, that the pallate alone is the fit way of expurgation when the creature hath good concoction, and that nofethrils do onely serue for the inspiration of aer and odours.

In his Commentary vpon the 24. Aphorisme of the third Section hee writeth, That the expurgation which is made by the eares is not Naturall vnlesse it bee in little children by whose eares we often obserue that their braines are purged.

In his Commentary vpon the 20. Prognost. of the first Section he saith, that the expurgation by the eyes is not naturall. Thus *Galen* seemeth to be of a diuers opinion concerning these passages of the braines excrements. But that we may reconcile these different places and freely professe what truely we are to resolute of; we thinke that the diuers excrements of the braine, Phlegmaticke, bilious and melancholicke are purged by diuers wayes, some of which are ordinary, familiar and accustomed to Nature, others extraordinary and not so conuenient.

The ordinary passages prepared for the expurgation of Flegme are the pallate and the nofethrils; but the pallate especially, because the Noftrils were primarily appointed for smelling. Anatomy teaches vs that out of the third Ventricle of the Braine there is a conspicuous passage to the inward Basis thereof, in whose extremity there appeareth a small portion of the thin Membrane which is first broader then groweth narrower like a Tunnell which the Grecians call *πυλὸν καὶ κοάνη*. The Latines *Peluis* and *infundibulum*. The Basin or Tunnell, through which the Flegmaticke humor is by little and little transcolated as it were through an *Hippocras* bagge. This waterish humor is receiued by a flegmaticke Glandule like a sponge, and afterward distilleth by degrees through the holes of the Wedge-bone into the pallar and mouth. But if at any time (which is not vnusuall) the vpper Ventricles of the Braine grow full of a mucous slime it droppeth through the proccesses which are like to the nipples of a womans paps into the *Os Cribiforme*, or spongy bone, and so into the Nofethrils.

The bilious excrements are continually purged by the eares. Some say that therefore the bilious excrements are throwne out by the eares that the heate and ficcitie thereof might keepe the bones of the eares dry and so more fit to receiue and report the sound. But the Phlegmaticke excrements are purged by the mouth and nofethrils, that those open passages by that humidity might be kept from drying vp. These therefore are the ordinary channels and most familiar to nature by which she purgeth the excrements of the Braine. There are also other extraordinarie wayes by which the Braine oppressed or surcharged with abundance of humor exonerateth it selfe. Such are the eyes, the Spinall Marrow and the Nerues from whence commeth the Palsie. There is also sometime a fall of humors through the Veines and arteries into the *Parotidas* that is the Glandules behinde the eares. But these are not the peculiar excrements of the braine, that is, of the Marrowy substance and of the Ventricles, but rather of the vessels as Veines and Arteries from whence proceed tumors of the glandules, inflammations likewise of the eyes and of the eares.

Now these excrements in a temperate Braine are moderate in their substance, quantity, quality and time of excretion. In the substance, because they are neither too thicke nor too fluid; in their quantity because they do not abound; in their quality because they are neither salt nor sharpe; in the time of excretion when they are auoyded after concoction.

There remaineth one scruple to be resolved, that is, by what wayes the superfluities of the *Cerebellum* and of the fourth ventricle are purged. We say for answer that the excrements of the *Cerebellum* and of the fourth ventricle are very fewe; as well because of the hardnesse of the *Cerebellum*, as also because in the fourth ventricle are contained most subtile, pure and well purged spirits, and therefore those few superfluities are easily dissipated. But the braine it selfe being in quantity very great and of temper very moyste heapeth vp abundance of superfluities which stand in neede of conspicuous passages by which they should be auoyded.

ZZ Quest.

QUEST. XIII.

Of the number and vse of the Ventracles.

Of the num-
ber of the ven-
tricles.

IN the History of the Ventracles of the braine there are many things controuerted which offer themselves to our consideration; and first of all the Anatomists doe differ concerning their number. *Galen* determineth that there are foure, two *superior* which he calleth *anterior ventricles*; the middle which is a common cavity and the backward. *Auicenna* numbrell but three; the vpper, the middle and the hindmost; esteeming the vpper two for one, because they haue the same figure, magnitude, seite, structure and vse. *Arantius* addeth 2. other vnder these which he nameth from the fig. *Hippochampi*; but I think that they are parts of the vpper ventricles, which indeed are so large that in common dissections scarce their third part is shewne. *Varolius* cutting the brain after a new manner sayeth there are but two; but because we haue at large made mention of his opinion in the Historie foregoing, we will not here weary our Reader with iteration thereof, but referre him thither for further satisfaction.

Of the vse of
the ventricles.*Galen* redeem-
ed.

Objection.

Solution.

The opinion
of some new
writers.

Concerning the vse of the ventricles, *Vesalius* taketh *Galen* about the vse of the vppermost two; because he sayth that they are the organs of smelling and that out of these by certain processes the phlegme is transcolated into the spongy bones. Wee answer for *Galen*, that the *anterior* ventricles are therefore called the Organs of smelling, because vnto them are odours brought of which also they iudge. Beside, what should hinder that the flegme (if the braine abound therewith) should not be transported from them by those processes into the spongy bones; seeing we find that sometimes (as in the *Apoplexie*) the phlegme is diffused through the whole body of the braine; and sometimes falleth into the nerues and the spinall marrow as in the Palsie? It will be objected that the sense of smelling would be extinguished if the phlegme should be transcolated by these processes: I answer, that sometimes when the Fluxe is continuall and the humor very abundant the smelling is lost, not so much by reason of the obstruction of the processes, as because the holes of the bone are intercluded.

Some new writers there are who thinke that the *anterior* ventricles were not appointed for the preparation and concoction of the spirits, as well because they are the receptacles of excrements, as also because the Animall spirits did not stand in neede of any sensible cavity. But *Galen* answereth, that Nature hath prepared them to serue both turnes; like as through the spongie bone odours doe ascend and surperfluities or excrements descend. As therefore those things which are auoyded euery day by the pallat and the nostrils do neither hinder the Taste nor the Smell if they be moderate: so it is in the excrements of the braine.

QUEST. XIII.

Which of the ventricles are most excellent.

Of the prehe-
minence of
the ventricles
of the braine.The vpper
ventricles are
the basest.The 4. the no-
blest.

CONCERNING the excellency or *superiority* of the ventricles of the braine some different places in *Galen* are to be reconciled. It is commonly receiued that among the parts of the Braine the ventricles are most excellent, not because they are particular seates of the Principall faculties, but because in them the Animall spirits are generated. That teacheth *Galen* in the third Chapter of his 7. Booke *de Placitis Hippoc. & Platon.* If saith he, you cut the braine any way the creature will not loose sense and motion before the wound pierce vnto some of the ventricle. But whereas there are foure ventricles it may be demanded which of them is most noble.

Galen teacheth that the vpper ventricles are the basest; In his 8. Booke *de vssu partium* and the 10. Chapter: in his 7. *de placitis*; and in his Commentary vpon the 18. Aphorisme of the seuenth Section, by the example of a young man of *Smyrna* a City of *Ionia*, who being wounded into one of the vpper ventricles yet escaped with life. Concerning the third and fourth ventricles *Galen* seemeth to differ from himselfe; for in the fift Chapter of his third Booke *de locis affectis* he yeeldeth the prerogative to the fourth ventricle. The Animall spirit

spirit, sayth he, is containd in the ventricles of the braine, especially in the hindermost, although the middlemost is not to bee contemned: which is as much as if hee had sayed the middlemost is not the noblest. For wee are perswaded by many reasons to esteeme this above the two vpper. In the third Chapter of his 7. Book *de placitis*; A wound in the hindermost ventricle doth most of all offend the Creature; In the second place the wound of the middle ventricle; but least of all if it be in the two vpper: the same thing may bee sayed of sections or bruises of the head. And these authorities of *Galen* are seconded by reason; for it is a perpetuall truth in the body of a man, that by how much the cavity is greater, by so much it is the baser. The fourth ventricle is of all the rest the least and the narrowest, and containeth the Animall spirit sincere defœcated and exquisitely purged: the other do onely prepare the spirit, and therefore the hindermost ventricle is the most noble.

According to
Galen.

Yet *Galen* in many places seemeth to say the contrary, as for instance in the 7. Chapter of his third Booke *de locis affectis*, and in the second Chapter of his fourth Booke, hee preferreth the third ventricle. If, saith he, at any time the whole fore-part of the braine be affected, those things which concerne the vpper ventricle are drawne into consent, and the action of discourse is vitiated; where, by the vpper ventricle he vnderstandeth the third or the middle: but why, I am not able to giue a reason. But if discourse be seated in the middle ventricle, then is it the most noble. In the last chapter of his third Booke *de placitis* expounding the fable which faineth Minerua to be borne out of the toppe of *Iupiters* head: Therefore, sayth he, they faigne her to be borne out of the top, because thereunder is seated the middle ventricle which is the principall of the braine and the originall of wise dome.

Galen seemeth
to say the con-
trary.

Mereouer the wonderfull structure of the third ventricle is an euident argument of the excellency thereof, as also because the wounds of the *Occipitum* are lesse dangerous then those of the *Sinciput* or fore-part of the head. So saith *Hippocrates* in his Booke *de vulneribus capitis*. More escape death that are wounded in the hinder parts of their heads then in the fore-part.

The reason.

You shall reconcile *Galen* if you say, that when he auoucheth the fourth ventricle to bee the most noble, then he speaketh according to his owne iudgement: but when hee preferreth the third he speaketh according to the opinion of other men, especially of *Herophylus*. For *Galen* did not attribute or assigne to the principall faculties particular mansions or habitations in the braine as we haue heeretofore prooued.

Galen recon-
ciled.

Againe, vpon a wound in the *Occipitum* or nowle of the head, the fourth ventricle is sildome offended, because there is much flesh and the thicknesse and hardnesse of the bone to resist the violence of the blow, whereas the bones of the *Sinciput* or fore-part are much more slender and weake.

In the whole history of the head I do not finde that *Galen* seemeth so much to wander out of the way as in the description of the *Rete mirabile* or wonderfull Net, for this in a man is so small that a good eye can hardly discern it. I like rather, saith my Autor, to call the *Plexus Choroïdes* (which is manifest and obuius to euery eye in the vpper ventricles of the braine) *Rete mirabile* or the *Wonderfull Net*, as also some of the new Writers haue

The error of
Galen in the
wonderfull
Net.

done: for in it the vitall spirit is attenuated and the Animall getteth a certaine rudiment. And thus are we come to an end of the Controuersies concerning

the Braine especially the substance thereof. Now let vs proceed

to the second part of the head which is called

the Face and so to the

Senses.

The end of the Seauenth Book and the Controuersies thereunto belonging.

THE EIGHTH BOOKE.
Of the Senses and their Instruments,
as also of the Voyce.

The Preface.

Although in the former Booke we have made mention of the Instruments of the Senses when we described the Coniugations of the Sinnewes of the Braine, yet because there are many other parts in the Head set apart for their vse, wherein the glorious wisdom of our Creator dooth most manifestly shine and in the preservation whereof we are deeply interested, I haue thought good to appropriate this Eight Book vnto the History of the Senses. Now in euery Sense there is a Matter and a Forme. The Forme is the Faculty which is yssuing from the Soule and differing in Name not in Nature as it informeth this or that Matter which is the Instrument. The first of the Senses is the Eye the most precious part of the body; and they are two, that if one should miscarry the other might supply the necessity of Nature. They are set like Centinels or Scout-watches in the top of the Towre, whence they may discern the farther off if any thing approach either hurtfull or behoouefull that we may apply our selues to it or auoyde it.

The eyes,

Galen is of opinion that the Head was placed vppermost in the bodie for the Eyes sake, because the Opticke Nerves stood in neede to be very short. For their security they are scituated in Caues and defenced about with diuers Muniments. Above them hangs a round arched brow to beare off and cast ouer what might fall from the Head, and betwixt them runnes the Nose as a strong wall, vnder them the bones of the Cheeke stand out, and at their side the hard bones of the Temples.

They are immediately couered with soft lids that nothing might impeach the delicacy of the instrument; the vppermost are moouable and very nimble which do shut vp the pupils as well in rest to refresh them, as also when any outward iniury is ready to annoie them; the lowermost are immoouable or at least mooued insensibly. These liddes are againe bearded with haire whereby and wherein small bodies or Motes which happly in their approach are not discerned might be intercepted.

The Eyes themselves haue many Muscles allowed them whereby they are mooued euery way, vpward and downward, to the right and to the lefte and round: they are also by a Muscle sustained and kept stable or firmed whereby the sense is more certaine. Diuers Coats they haue wherewith they are couered, the first called *Adnata*, the second *Cornea*, the third *Vnea*, the fourth *Aranea*. There are also three Humors, the first *Watery*, the second *Glassy* and the third *Christalline* which is the chiefe Organe of the sight, and is assisted by the other parts aboue mentioned. The eye indeede seeth with the *Christalline* humor, but it seeth perfectly and more accomplishedly with the whole Organe or Instrument. The object of this sense are those colours which are in the superficies of other bodies.

The Eares.

Next followeth the Eare, the Instrument whereby the Soule discerneth of all manner of sounds and voyces. The chiefe part of this Organe is a thin and subtle ayre bredde in the eare and seated within the cauity thereof; to which aire the ends of the Nerves of hearing which come from the Braine doe attaine: and as the Opticke Nerue encompasseth the *Christalline* humour, so this nerue of Hearing is thought to encompassse the *In-bred Ayre* and

and spirit, and so the society growes betweene the instrument of the Sense and the inward principle of Sensation. Before this Ayre is a Membrane stretched which we call the *Drum* supported and established with three Bones, the smallest of the whole body, but none formed with more curious Art; the first is called the *Hammer*, the second the *Anvill*, the third the *Stirrop*. Many men haue laboured to assigne to each of these their proper vses and how they conferre to the sense of Hearing, but truth to say, their discourses do rather fill then feede the minds of their Reader.

God hath reserued many secrets in mans body to himselfe, whereof wee iustly thinke this is one; yet we know that they sustaine the Membrane of the Tympane against which the representation of the sound or voice is beaten and communicated to the inbred Ayre. These sounds are admitted to the Instrument by the hole of hearing, a hard & dry entrance full of embowed Meanders and Convolutions, lest the outward aer falling or rushing suddenly vpon the *Drum* should endanger the breaking thereof. Without the Eare there standeth a gristly substance which partly defendeth the hole of Hearing that nothing fall into it, partly catcheth and staith the sound that it passe not by.

The third Sense is that of Smelling, whose Instrument doth not yssue out of the Scull in those Creatures which do respire, but is conteyned within the substance of the Braine: whence it followeth that these 5. are called outward senses, not because they appeare outwardly, but rather because their proper organs doe receiue the species or representations of outward things. The instrument therefore of smelling is a paire of productions issuing out of the forward Ventricles of the Braine, in which the faculty of smelling residing doeth comprehend the odors of things which together with the aer are drawne in thorough the passages of the nose, which is rayed higher in the face of a man then of other creatures, as well for beauty, as because the Braine of a man being large and therefore yeelding abundance of excrements might there-through bee better clenfed. This nose is diuided in the midst by a gristly substance, aswell to breake and diuide the outward ayre which in a great part is drawne in this way to be conueyed into the sharp arteries and so to the lungs; as also to disperse the parts of the object of this sense, that being so diuided it might equally insinuate it selfe through the smal holes of the spongy bone to both the productions which determine on either side.

The Nose.

The fourth Sense is the Taste, the Forme wherof is seated in those Nerues which attaine vnto the tongue and pallat assisted by the spongy flesh of the tongue it selfe. For when any sauour quality or affection imparted to a humor or iuice is applyed vnto the tongue; it stirreth vp the taste, and presently the image or species of that sauour is by the spirit residing in the Nerues conueyed to the principall Sensator; and if it happen that the sauour be represented to the instrument in a hard or congealed body as salt, pepper or such like, it cannot moue the sense before it be melted by the heate, or at least haue communicated his affection vnto the moisture of the mouth, and therefore it is that nothing can affect the taste which cannot be dissolued, neither is he whose tongue is torrifed or parched with extraordinary heate a competent iudge of sauers or Tasts.

The Tongue.

As for the Touch which is the fift and last sense; it is not contained within any proper organ or instrument but equally diffused through the whole body, because the necessity of Nature did euery where require the presence thereof for the security of the life of the creature; and yet notwithstanding it dooth not (as other senses) receiue the impresson of all his owne proper objects. For sensation is a passion: if therefore the Object be of the same temper with the Instrument, the sense is not affected therewith, because it doth not suffer by that which is like vnto it; but all the other senses do apprehend all those qualities which do fall vnder them; for being all vnlike to the instruments they must needs be affected by them. But because this sense hath no particular instrument in the head, we shall onely intreate of it by the way in this place; somewhat we haue spoken of it before in our discourse of the skin, and more we shall haue occasion to say in the booke of the Ioynts and the Vessels. Wherefore we descend vnto our History.

The sense of Touching.

CHAP. I.

Of the other part of the head which is called the Face, together with the vessels and muscles thereof.

The Names
of the face.

 Auing gone through that part of the Head which is covered with a hairy scalfe and therefore by Aristotle in the 7. Chap. of his 1. Book *de Historia Animalium* called *πρὸς ὀφθαλμὸν*; it remaineth that we proceed vnto the other part which is without hayre called in a map *πρόσωπον*; which name it seemeth to haue receiued from the thing it selfe, saith the Philosopher in the 1. Chap. of his third Book *de partibus Animalium*, because a man *πρόσωπον* "οὐρα", that is, looketh forward; for of al creatures only man goeth vpright and looketh directly forward. The Latines call it *Facies*, in the comely conformation and Beauty whereof the elegancy of the humane nature doth most appeare. It is also called *Vultus à voluntatis indicio*, because it bewraith the disposition of the will, and is especially changed according to the variety thereof. We call it the Face or the countenance.

The parts of
the face.

The parts therefore of the Face are two: the vpper is properly called *μετωπὸν* *Frons*, à *ferendo*, because it beareth in it the Passions of the minde, we call it the Forehead whose lowest parts are the eye brows. The second and lower part of the Face beginneth at the eye-brows and reacheth to the bottome of the Chinne, in which there are many parts. Both these parts of the face haue also some parts conteyning and some conteyned. The containing parts are common or proper: common as the cuticle or scarfe-skinne and the skinne it selfe; which in this face, in the fingers ends, in the Yarde and the Cod is most thin. This skin in the Cheekes for the most part looketh red because of the affluence of blood from the ytter branch of the externall Iugular veine; which is disseminated betwixt it and the fleshy membrane. This skin is furnished with hayres; about the eyes for their security; about the mouth in men as an argument of their virility and a peculiar beauty of that sexe; for in a woman those hayres are an especial deformity. Hence also (saith Galen in the 14. Chap. of his 11. Book *de usu part.*) a man becommeth more venerable, especially if when he be growne to a ripe age the haire also do plentifully compasse his mouth on euery side, for which cause also nature hath left the Cheekes and the Nose bare and without haire.

The skinne.

The hayres.

The perfora-
tions of the
face.
Their vse.

This skin of the face is diuersly perforated for the eyes, the eares, the nostrils and the mouth; partly that the sensible objects might haue the freer access; partly to intromit aire and nourishment, and to auoide excrements. And these perforations if their actions be alwayes required are alwayes open. As the nostrils for respiration, the eares for hearing because these two were alwaies necessary. As for those whose functions were not so indefinent, especially in the time of sleepe and for the auoyding imminent dangers, those perforations I say, for more security may be shut as the eyes and the mouth.

The fat.
The fleshy
membrane.

The fat of the face is very little and that that is, is about the Cheekes.

The vessels
and the glands.

The fleshy membrane which in the rest of the body is almost wholly neruous, in the forehead is fleshy and musculous; so close ioyned to the skinne that it can hardly bee separated therefrom. And it is red because of the muscles of the face which grow vnto it. Betwixt this fleshy membrane and the skin the veines before spoken of do runne, where also are many glandules dispersed, as vnder the rootes of the eares in which the disease is bred that wee call *Parotia*, as also betwixt the lower Iaw and the inferior part of the Cheekes where those Tumors arise which we call *Scrophule* or the Kings euill.

The proper
contayning
parts.

The proper containing parts are muscles, bones and gristles which make the frame of the face it selfe. The muscles are, of the forehead, of the eye-brows, of the eye-lids, of the nose-thrills, sometimes also of the eares, of the lips, of the lower Iaw, and of the Cheekes. The bones are, the forehead-bone, the 6. bones of the eyes, three of the Nose, 6. of the mouth, that is to say, two of the vpper Iaw, and two of the nether Iaw, and as many of the Palate. The Gristles are, of the eares and the nose which are diuersly ioyned with the bones.

The parts
contained.

The parts contained in the face are the seates of the foure senses; whose organs either it containeth as it doth those which haue no place within the skull, or else it prepareth a way for them that lye hid within the Scul.

These Organes of the senses are the Eyes, the Eares, the Nose, and the Mouth, wherein are contained the Tongue and the Throttle which are the instruments of the taste and the voyce. And indeede because the Organes of the senses are placed in the face, it is truly called

called the Image of the minde, for as *Laurentius* saith truely, in the eye-browes dwells pride, in the Cheekes shamefastnesse, in the Chinne maiesty, in the Forehead wisdom, finally, in the whole countenance beauty and honesty. But to speake more like a Physitian, in the Face doe appeare the manifest signes of life and death, and therefore *Hippocrates* in his Prognostiques commands the Physitian first of all to take view of the sickmans face, whether his countenance be like that it was in his health, or whether it bee much changed in colour, figure and magnitude.

How the
mind shineth
in the Face.

But before we come to the particular handling of the Organes of the Senses, it shall not be amisse to giue you in this place a light view of the Vessels of the Face and of the Muscles which mooue the skin of the Head. The Vessels therefore which are deriued through the face are Veines and Arteries. The Veines are called Iugulars, whereof one is internall, [Tab. 6. lib. 6. S S] of whose distribution we haue spoken in the eight chapter of the precedent Booke. Another externall [Tab. 6. lib. 6. T T] which ariseth out of the vpper part of the *Subclavian* branch, and ascendeth on the sides of the necke vnder the chin, yeelding furcles to all the outward parts of the Necke, the Head and the Face on his owne side. But for the most part vnder the roote of the eare, [Table 6. Lib. 6. V] it is diuided into an vtter branch [y] and an inner. [x] The inner branch reacheth vnto the muscles of the mouth, the chops and the bone *Hyois* as before is saide. The vtter creeping along the skin and the Muscles and skin of the head, beeing vnder the eare supported with Glandules, is parted into two branches, whereof one bending vnto the foreside of the face [Tab. 6. lib. 6. Z] attaineth vnto the Nose and the Cheekes, and in the middle of the forehead is ioyned with a branch of the other side, and maketh the fore-head Veine which in some cases wee vse to open, [Table 6. lib. 6. a] The other branch passeth by the side and sprinkleth his branches partlie

Prediction by

 l, The distribution of the branch g vnto the Cheeks and the Muscles of the face.
 m, The distribution of the branch g vnder the roote of the eare.
 n, The same branch creeping vp the Temples.
 o, And the backside of the eare.

vnto the Temples [Table 6. Lib. 6. e] partly vnto the *occiput* or Nowle of the head. Furthermore the branches of this exterior veine both in the face and in the crowne of the head are diuersly mingled, from which certaine small threddy strings are distributed into the seames of the Skull and the manifold perforations thereof. And so much for the veines of the face.

The arteries
of the face.

The arteries called *Carotides* or the sleepy arteries [table 13. Lib. 6. XX] being on each side one, ascendeth vp on the sides of the necke, together with the *Iugular* veines, directly vnto the head, and when they come vnto the chops or Fauces they are deuided [tab. 13. lib. 6. ff] into an exterior branch [g] and an interior [h].

Of the distribution of the interior we haue spoken in the eight Chapter of the former Booke. Now concerning the exterior. The exterior which is lesse then the interior and is seated without the Fauces reacheth his surcles vnto the cheeks [Table 13. Lib. 6. l] and the muscles of the face; afterward when it commeth to the roote of the eares [m] it is parted in twaine. One of them creepeth to the backside of the eares at [o] from which two arteries do vnder the eare passe into the lower iaw, and according to the length thereof are dispersed vnto the rootes of all the lower teeth: but another part yssueth at the hole which is in the chinne, and so creepeth along the neather lip. The other artery of the by-partition at

[p]

[E] creepeth vp the temples and the forehead and is consumed in the muscles of the Face. And so much of the vessels.

The Skin of the head is in many men mouable, but of the forehead in all men; not onely by the benefite of the fleshy membrane, which degenerateth into a musculous substance hauing right fibres, but also by the help of two muscles; assured so to be, both by the course of their fibres, as also by their motions which appeare in these after the manner of other muscles and not like the motion of the fleshy membrane. These are scituated in the forehead [Table 6, Figure 1. A] and doe arise aboue where the hayre determines; sometimes as high as the crowny seame neare the Temporall muscles; the right at the right and the left at the left Temple, (where the fleshy membrane cleaueth so close to the *Pericranium* or skul-skinne and the Skull it selfe, that it is altogether immouable: so that the forehead and the Eye-browes are mooued when the membrane is at rest) and toward the common seame which distinguisheth the bones of the head from those of the vpper iaw, are implanted with right fibres aboue the eyes and the nose into the skinne at the browes as at the parts which are to be moued.

The muscles of the forehead.

I sayd these fibres were right and not oblique as some haue thought: and here Chyrurgions must obserue that in opening Apostemations in that place they make not their incisions ouerthwart as the wrinkles of the skinne doe goe, but according to the right fibres.

A good note for Chyrurgions.

These two muscles are a little disioyned in the middest, and that is the reason why the top of the forehead is not moued. Vpon this coniunction some haue thought them to bee but one muscle. Against whome we shall further dispute in the proper place where we treat of these in our booke of muscles. There are also other muscles which draw the skinne of the head backward, but those belong not to this place.

Why the top of the forehead is not moued.

Now we proceed vnto the Organs of the Sences.

CHAP. II.

Of the Eye and parts thereof.

As I sayd before that the habitations or residences of foure of the Sences were contained in the face.

The fift externall Sence, which is the Sence of Touching is dispersed through the whole body and hath no proper seat in the face, as all the rest haue. For the head being the seat of the Animall faculties and the habitacle of the reasonable Soule; it was also necessary that the Sences (which as *Hippocrates* in his Booke *de morbo sacro* or of the Falling sicknesse, sayth, are the messengers and interpreters of the Soule) should also haue their residence in the head.

These outward Sences are fise as there are fise simple bodies, the Heauen and the foure Elements. Wherefore according to the *Platonists*, the Sight answereth in proportion to the Element of *Starres* whose obiect is shining. The obiect of the Smell is fiery, and therefore it is sayd that *fragrantia* are *flagrantia*. The obiect of the Hearing is ayrie: the obiect of the Taste is watery, and of the Touch earthy. But amongst these the sight is the principall, which with hearing makes a mannes life much more happy, albeit without the Taste no man can be so well nourished. For those who eyther by Nature or by Accident are blind do account themselues therein miserable; for as the Sunne (saith *Galen* in the 10. Chapter of his third Booke *de vsu partium*) in the great world, so is the Eye in the body of a Creature; and therefore *Hesychius* calleth them *ἡλίου πύλαι* *Solis porta*, The dores of the Sun; and therefore we will first intreat of the Eyes, as also because amongst all the nerues the Optick nerues haue the first place.

Why 5. sences
How the sences
answer the elements.

Galen:

Hesychius:

The Grecians call the Eye *ὀφθαλμός* *quasi* ὁ πόνος *δράματος*, because it is the couch or bed out of which the Sight shineth. And therefore the Eyes are called by others *παύλα*, because from thence that is the light proceedeth. The Latins as *Varro* and *Lactantius* call them *oculi*, *ab oculando vel occultando* from hiding, because they are couered and hidden within their Liddes.

The names of the Eyes.

These Eyes are the Organs of the faculty of Seeing, which we vse (sayth *Galen* in the fift Chapter of his 8. Booke *de vsu partium*) as spies, not only to auoyd those things which wold of.

Their excellency.

offend vs, and to leade vs vnto that which is profitable, which vse is common to vs with brute beasts, but especially that by those things which are visible we may take consideration of the omnipotency of the inuisible God. Hence it is that *Plato* saide well, that if wee wanted our Eyes we should be ignorant of that excellent order which Nature hath established in the frame of the world and of our owne bodies. *Aristotle* addeth that the Science or exquisite knowledge of all things is exceeding much furthered by the eyes. And therefore *Galen* calleth them diuine members: Seeing therefore their necessity is so great it is no wonder that God the Creator made them after so excellent a manner as it were a curious modell to manifest his Maiefty and wisdom.

Their situation.

They are scituated in the head as in the highest and best defended place of the body, immediately vnder the forehead as Scoutwatches: for as watchmen are placed in high standings and turrets that they may further off discern whether any enemies be approaching or ly in ambush, so the eyes are set aloft to foresee and giue warning of any danger that may be toward vs. *Galen* and *Auicenna* haue conceived that the head was especially made for the vse of the eyes, their reason is, because the opticke nerues being very soft, could not safely be placed farre from them. They are seated in the forepart of the head, whereof *Galen* in the first Chapter of his tenth Booke *de vsu partium* rendreth a reason, because (saith he) the Instruments of this sense do require soft nerues which could not be produced from the *Cerebellum* or After-braine as being much harder then the braine it selfe.

The reason thereof.

Moreouer being placed before, they are directly opposed to their objects, and we moue forward, neyther can we discern cyther on the side, or behind vs, vnlesse wee turne our heads about. They are seated within bony cauities which *Pollux* calleth *οφθαλμοι* or Orbes, & that for security; haply also because the spirits might be lesse dissipated.

Their number

They are in number two, (as also are the other instruments of the senses) mooued together and at once with the same motion, that the sight might be more perfect; for if one of them had beene lifted vp and the other depressed, then euery object howsoeuer would haue appeared double: for it was necessary that the axes or diameters, that is, the imaginary lines of the pointed objects should determine in one and the same place: and this ioynt action of the eyes is assisted by the coniunction of the mouing sinewes in their originall as we haue already declared. Obserue further with *Aristotle* in the 17. Probleme of the 10. Section. That amongst all Creatures a mans eyes stand neereft together for his proportion.

Their figure.

Their figure in a man is round and sphericall [Table 2, Figure 3, and 4] but in other creatures they are not perfectly round, but eyther oblique or depressed, [Table 2. fig. 5.] and no maruell seeing the whole figure and fashion of a mans body differs so much from other creatures. But if you consider them together with their muscles which grow to their back-sides, then is their figure turbinated like a sugar-loafe. [Tab. 1. fig. 4, and 9] The reason why they were made round, was partly that they might be more capacious because they were to containe many parts of great vse. Againe, that figure is the strongest and lesse subiect to offence by outward iniuries. Finally, their roundnes makes their motion more nimble, to which end also they are smooth and slippery that we might command our sight euery way at our pleasure and vpon the suddaine. Wherefore the Maisters of the Opticks say that because of the orbicular or round figure of the eye, the beames from which side soeuer they come are broken at the Perpendicular, that is to say, they arriue directly in the center of the eye. Their magnitude is proportionable to the magnitude of the body and their owne vse. And heere we are to consider two kindes of parts; the one of those which are disposed about the eyes for their defence: the other, whereof the eye is compounded.

Their magnitude.

For defence Nature hath compassed them with bones which frame their Orbe, and beside these they are walled, aboue with eye browes, before with lids, and in eyther place fenced with hayres and the skin. For first of all the brim of the eye-lids stand as a wall of defence with their hayres shot out that no small mores or other annoyances might fall into the eyes when they are open. Then the lids themselues, that closing together they might shut vp the eye if any greater body or more violent offence should bee offered thereunto. Furthermore, to defend them from violence, aboue they are secured by the eyebrowses, below by the Cheekes, at the great angle with the Nose, at the lesser by the production of the yoke bone, and so if any greater body do rush against the eye, it is receiued by one of these, the eye which is in the middest remaineth vnoffended. The motion also of the skin as well that of the forehead as also that of the Cheekes is a great security vnto the eye, for the skin being contract the eye is as it were drawne inward, and the same againe extended openeth them

How they are defended.

Their parts.

them wide. The orbe of the eye is round, [table 2, lib. 7. fig. 6, at Q. tab. 12. fig. 8, betwixt X and R] that therein the eye might be better rowled: long, because of the muscles whereby the eye is mooued, and compassed with a *Periostium* or thin membrane. It is formed of the bones of the head and of the vpper iaw. But *Aquapendens* addeth also the spongy bone which we call *Ethmoides*. The bones of the head which make the orbe of the Eye, are the forehead bone and the wedge-bone, whence it is that in these dennes of the Eyes there be many sutures and holes to be found. The forehead bone whose outward seat or table is smooth, maketh the vpper Arch of this rooffe: and where the tables are ioyned againe, there in the place of the Eye-browes it buncheth outward [tab. 3. lib. 7. fig. 8. ARX] and so defendeth the Eye. The wedge-bone is in the backe part of the hollownesse or cavity of the orbe, where it is perforated with foure holes. [tab. 3. lib. 7. fig. 8. neare DG] The bones of the vpper iaw which help to make the orbe of the Eye are: the first which maketh his outward eminence below. [tab. 3. lib. 7. fig. 8. r] The second and the third [tab. 3. lib. 7. fig. 8. ΔΘ] are in the inside, very thin bones, because the protuberation or swelling of the nose is also a defence in that place. The fourth bone of the vpper iaw lendeth a part to the framing of this orb where the cheekes rise vp into a swelling prominence. [tab. 3. lib. 7. fig. 8. neare i.]

The bones of it.

The sutures or seames in the bones of the iaw are three; one at each angle or corner, the third in the lower side of the orbe: the sutures of the spongie bone are two, both at the great angle. Finally, there are other sutures betwixt the wedge-bone and the forehead-bone. And vpon these sutures are the *Pericranium*, the lower oblique muscle and the pully suspended.

The Sutures of it.

The holes in the orbe are three and those very large; one in the hindmost part which is round, made for the transmission of the opticke nerue, the second is in the lower part of the cavity of the orbe, and is a long rift through which the nerue which mooueth the eye together with some veines and arteries are deriued vnto the Eyes and their muscles. The third is at the inward angle and perforated into the bones of the nose, through which holes sometimes a part of the teares do yssue,

The holes 3.

In these orbs of the Eye doe arise on either side two *Sinus* or circles, which *Aristotle* in his first Booke *de Historia Animalium*, calleth common parts of the vpper and neather Eye-lid, because they are made of both the Liddes extended out in length. These circles the Grecians call *nasol d'ro rē n'nd'ed'ra*, that is, from a Sence of Itching, because in them oftentimes by reason of the teares or of some other humour we finde a notable itching.

The angles or corners,

The Latines call them *anguli oculorum*, we the corners of the Eyes, wherein the teares and whatsoeuer yssueth from the Eyes is gathered together. The outward angle or corner toward the Temples is called *Canthus minor* or *externus*. The other inward to the nose *Canthus maior* & *internus*. [table 1. figure 1, and 6. e sheweth the greater corner and d the lesse] *Pollux* calleth the greater angle *παρὰ τὴν ὕδρα* the waterer, and *Hesychius* *πηγὴ* or the fountaine, because from thence the teares doe yssue.

Their names.

But these names I take to be fitter for the orbe it selfe then for the corner of the Eye, for in each angle in the very extremities or ends of the ridge of the eye-lid both aboue and below there are two holes [tab. 1. fig. 4, 7, 8. m n] which in the lesser corner can hardly be perceiued when a man is aliue, but after death they are not at al conspicuous: but in the inward and greater angle these holes are larger and easie to be perceiued if wee marke them well especially in women; whence haply it is that they haue teares at command. But in the eye of an Oxe euen after he is dead they may easily be demonstrated [tab. 1. fig. 4. m n, fig. 7, and 8, they are onely expressed in the greater corner at n.]

The holes of the eyes,

Why woemen haue teares at command:

These holes are called by *Fallopins* in his obseruations *Puncta Lachrymalia*, as also by *Platerus*, because thorough them the teares doe distill, especially by the greater, which nature vseth rather and oftner then the lesse, because the scite thereof is more declining. Although there is a more open way for them through the nose, the bones of the vpper iaw being notably perforated in the top of the nose, which holes haue certaine passages, which vnder the caruncle are vnited into a common bosome ending in the cavity of the nose, and this cavity is properly called *πηγὴ* that is, the fountaine.

Puncta Lachrymalia.

But this Bone because it is of it selfe thin and hollowed, beside by the passage or canale before spoken of is sometime exulcerated by the Acrimony either of other humours or of the teares; which sayth the Philosopher in the 35. Probleme of the fift Section, are like vnto sweate: and this kinde of Vlcer is called *Fistula Lachrymalis*, wherein if you presse the inner corner of the eye, you shall find a *Sanius* or mattery substance to yssue.

The disease called *Fistula Lachrymalis.*

Banbina's opi-
nion.

wounds of the
face are moist:
why.

The matter of
the teares.

The great ca-
pacity of the
orb of the eye.

The inconue-
nience of the
moisture de-
tained:

This matter is also oftentimes thinner, of which *Hippocrates* speaketh in his Booke *De Præca Medicina* where he saith, that oftentimes there is a Flux of humors even to the eye whose acrimony exulcerateth the eye-lids, & the parts vnder them it gnaweth asunder, yea sometimes it eateth thorough the coate that compasseth the Apple of the eye. That therefore this exulceration might be prevented, Nature hath set at the inner angle a Caruncle or glandulous flesh which the Grecians call *ὀφθαλμὶς* or *ἐπιμάστιξ*, although *Agineta* giueth it that name onely when it is growne about the due proportion. *Galen* eleventh Chapter of his tenth Booke *de usu partium*, calleth it *σῶμα σαρκώδες*, *Corpus Carneum*, The fleshy body. [Tab. 1, Figure 7, 8. r] This Caruncle was made to defend the bone from the sharpenesse of the humors. Moreouer, it serueth for a couering whereby the perforations which wee saide before were made through the bone, are as it were stopped with a sponge, through which the excrements of the eye may soke into the nose, but cannot returne againe to offend the face, or to make vs alwayes weepe. Wherefore, those whom we call Oculists, that is, such as professe and intend the cure of the eyes; must take heed that they do not vse such sharpe Medicines as may colliquate or dissolue this Caruncle. For wee haue often seene that Medicines applied to the eyes haue through these holes past into the nose, and so haue beene cast out either by emunction or by the mouth. But because wee are come to make mention of teares, it shall not be amisse a little to stand vpon the nature and manner of the auoyding of them.

Plato, *Aristotle*, and *Theophrastus* do thinke the teares are a kinde of sweate, or at least much like thereto. *Aquapendens* his conceite how agreeable it is to reason let others iudge, sure it is very quaint and witty, his words are these. The Tears are an excrement of the third concoction in the eye, proceeding from the nourishment of the Glassye and Cristaline humours; which excrement is engendred of blood as of his proper matter, yet is that blood diuersly altered by the temper of the eye. For from these humours of the eyes there is a double excrement separated; one thicke, another thinne. The thicke excrement is that blacke slime which cleaueth to the Coats called *Vnea* and *Choroides*. Another thinne which are the teares to which a whayie or serous humidity may be added. Thus far *Aquapendens*.

But *Banbina* is of opinion that these teares are the excrements of the Braine, whome happily it will be more safe to follow. Now whereas in euery concoction there is a double excrement separated; one thin another thicke. In this concoction which is celebrated in the Braine, the thicker excrement which is viscid and crasse Flegme is spit out of the mouth from the pallate or else descendeth by the nose. The thinner excrement is partly euaporated insensibly, partly it commeth away very manifestly, and sometimes mixed also with a more crasse excrement: now it moyleneth the tongue and the mouth to make the speech freer, and to helpe mastication or chawing of the meate. Sometimes it is transported to the whole face, but especially to the cheekes, to the temples and the eares; which may bee prooued by wounds inflicted vpon those places, which though they seeme to be healed, do yet notwithstanding for two or three months together euery day yeeld a great quantity of pure and waterish humour, issuing by the hole that is left in the wound, which no art is able to consolidate or make vp, which obseruation we confesse we haue from that notable Anatomist and Chirurgion *Aquapendens*.

That moisture which is transmitted to the muscles is the matter of teares, to wit, that whay which together with the blood is transported vnto the braine to be *ὀφθαλμὶς τροφή*. The vehicle of the nourishment, that by the help thereof the blood might be able to passe through the small vessels which are dispersed through the substance of the braine, which whay beeing not fit for nourishment, in the nourishing of the brain is percolated through his thin substance, as the whay is separated from the milke. This moisture is gathered together in the bony orbe of the eye, which is indeed of so great capacity that the fourth part thereof is not filled by the muscles and nerues of the eye. It remaineth therefore after the manner of other excrements a conuenient time in that cavitie, and is sucked or drunke vp partly by the fat, partly by the Glandules which are of a rare and spongy substance. The reason why Nature detained these excrements in the orbe of the eye was to moisten the Muscles, which because of their continuall motion were not onely in danger to bee overheated, but also to be exiccated and dried vpp; vnlesse they had beene moistened and refrigerated by this matter of teares which swimmeth in a manner about the fat and Muscles of the eye. And this vse hath the moisture if it bee moderate, for if it be immoderate and de-

detained in the eye, it hindereth the motion of the muscles: wherefore Nature being heere-in very prouident and wise hath framed & prepared two wayes for the expurgation thereof. One by the corners of the eyes, another by perforations into the bones of the Nose as we saide euen now. For if the teares should perpetually drop out at the eyes they would haue deformed the face, as we perceiue by those who are troubled with the disease before named called *Fistula lachrymalis* or the dropping Fistule.

Nature therefore studdying to preferue the beautie and comelineffe of the face as also the cleerenesse of the sight hath provided meanes to moue them by expression or by dilatation and attraction. By expression the teares are mooued eyther when we rub our eyes, or by the coldnesse of the ayre, or by the winde, or by some grieve of minde and weeping fit; at which times they drop out like plentiful sweate, or rather like a bubling streame through those holes which we saide before were formed in the terminations of the brims of the eye-lids: for at such times the muscles of the face and of the adiacent parts doe contract themselues sometimes with waylyng and mourning, sometimes without; sometimes

The moving
of teares, how
many wayes.
By expression.

the Respiration being cut off in the middest with a sobbing stay and the voyce broken about the top of the *Larynx*, yea sometimes quite intercepted: and thus is this matter of the teares moued by Expression.

2. by dilatation
Hippocrates.

By dilatation they are drawne out sometimes by heat, often by laughter, sometimes by the Sunne, for sayth *Hippocrates* in his Booke *de videndi acie*, the Eye being not able to resist a bright object, calleth out the matter of the teares to succour it, which also in the conflict is heated. Anger also and a sharpe Ague doe by dilatation prouoke and call out the matter of the teares.

Aristotle.

And in such an Ague sayth *Hippocrates* in his first Booke *Epidemion* (if other signes be not mortall) teares so appearing doe foreshew a Fluxe of bloud by the nose. That these are the very causes of the profusion of Teares, we may gather out of *Aristotle* in the 13. Probleme of the fift Section. *Aquapendens* is of opinion that Nature purgeth the teares by an expulsive faculty giuen to the Eyes to auoyde offences; for sayeth he, by this meanes, not onely Nature is vnburnded but also the eyes are moystned and so defended from the contact of cold and heate.

Obiection.

But not to contend about this matter, it may further be obiected that we oftentimes see at once so great a quantity of teares as cannot possibly be imagined could bee containd in the orbe of the eye. I answere, that this serous humor followes by consequence, euen as phlegme doeth fall out of the braine. And thus much shall be sufficient to haue bene spoken of Teares and the manner of their euacuation.

Solution.

The glandules
of the eye.

At either angle of the Eyes (as also *Galen* hath obserued in the 11. Chapter of his tenth Booke *de usu partium*) are placed certaine glandules or kernels, sometimes two sometimes more; that with their rare and laxe substance they might sucke vp that serous excrement of the braine, by which the outward superficies of the Eye is moystned, and which (as we said) is the matter of the teares. And this moysture thus gathered in the glandules is at conuenient times euacuated by the corners of the Eye and by the terminations of the brimmes of the lids.

Fallopian.

Fallopian in his obseruations sayth, that there is but one Glandule in each corner, which is found in the vpper part of the Eye neare the vtter angle, the inuention of which he also attributeth to himselfe. Moreover these glandules do serue as soft pillowes that the Eye might not be offended in his motion at the hardnes of the bone. And in men this is on this manner: But in brute beasts it is otherwise; which it shall not bee amisse to signifie in the fauour of young beginners and Practitioners in Anatomy, who doe often dissect the eyes of Oxen and Sheepe to make them more perfect when they doe come to the eyes of Men.

Their vse.

The same in
an Oxe.

In an Oxe Eye therefore is found another glandule in the inner corner, callous and harder then that in a man, which should seeme to bee there scituated because of the membrane with which they wincke, which membrane is most like to that we cal the Naile of the eye, very thinne and like the horny coate, or something of the Nature of a gristle. This Naile or membrane of which *Aristotle* speaketh in the 12. Chap. of his second Book *de Historia Animalium*, is moued with voluntary motion to the outward angle and couereth the eye euen when the lids are open. For about the roote of this callous glandule there cleaueth a strong membrane, whose vse haply is, that while the Skin is drawne to the opposite angle, that glandulous body should be stretched or bent like the horne of a bow, and when the skinne is remitted, returne backe and draw it into his proper angle. And truly this membrane is drawne to the opposite angle by a double cord, the one is aboue, the other below lurking vnder the coate of the eye which we cal *Adnata*, and arising from a certain muscle scituated in the vtter angle, which muscle *Fallopian* accounteth to bee a part of that muscle which draweth the whole eye outward. And thus much concerning the parts of the orbe of the Eye.

A membrane
in the eye of
an Oxe.

CHAP. III.

Of the Eye-browes and Eye-lids.

The eye
browes.

He Eye-browes with *Aristotle* in the ninth Chapter of his first Booke *de Historia Animalium* we referre vnto the Eyes. They are called in Latine *Supercilia* because they be *super cilium*, that is, aboue the haire of the Eye-lids. *Hippocrates* in his Booke *de locis in homine*, as also the rest of the Grecians after him call them *opous*. They are,

are, sayth *Rufus*, hairy extremities of the forehead, or haire that grow about the eyes which are distinguished vnder the forehead on either side. These eye-browes are compounded of skin, fleshy fibres produced from the muscles of the forehead, fat and haire. The skinn is thicke and hard, thicke the better to defend the eyes, hard, that the haire might neyther be too many, grow into too great a length, for euen as saith *Galen* in a marriſh and weeping ground no grasse is brought forth neither yet in a squallid and hot soile, so when the skin is either too dry or too moyſte the haire cannot grow.

Whereof they are compounded. Aft comparison out of *Galen*.

These haire are called by the Physitians as *Pollux* witnesseth *τοιοῦτο*, and are bred with vs when we first come into the world, as also are the haire of the eye-lids, whence it was that the Egyptian Priests who vsed to shau all their haire did notwithstanding suffer these to grow. And although these haire are of an equall length, number and thicknes, yet are they not right but grow crooked and oblique, bowing after the roundnes of the eye, that they might the better avert and turne aside whatsoever shall fall toward it. If they had bin too short, too few, or too thin, they would not so well haue defended the eyes. Againe, if they had been too long or too bristly they would haue bin an impediment to the sight. In some men saith *Aristotle* when they grow old they encrease vnto such length that they stand in neede to be cut, the reason wherereof he rendreth in the 15. Chapter of his second Booke *de partibus Animalium*; because they are placed in the coniunction of the bones which in old age are loosed, and so a greater quantity of vapour yssueth from their disjunction. But how the disposition of the minde may be obserued from these haire according to *Aristotle* in the 9. Chapter of his first Booke *de Historia Animalium*, and how the ancients (as *Cicero* reporteth in his oration for *Roscius*, and in the first booke of his Offices) placed a part of the Soule in the eye-browes, *Bauhine* hath well declared in his Booke *de partibus externis*, to whom we refer him that desireth further satisfaction.

Why they grow long in old men.

The middle place betwixt the eye-browes which for the most part is without haire is called by *Rufus* and *Pollux* *μεσότης*, in which place *Straton* the Philosopher as *Plutarh* reporteth placed the seat or principall residence of the Soule.

These Eye-browes although they be drawne vp by the muscles of the forehead; yet in some men (saith *Iulius Casserius Placentinus* out of whome we haue taken their fig. (there are two muscles found in the *occipitium* or nowle of the head [*tab. 4. fig. 1. C. the other in the second fig. at a. is retracted above the nose like the pannicle innerted*] which leading the skin of the head backward doe also draw the eye-browes with it, as we shall shew in the fourth Table figure 2. C, where also we will exhibite the orbicular muscle which draweth the eye-browes downward.

How they are moued.

Concerning the vse of the Eye-browes, the Philosopher in the 15. Chapter of his second Booke *de partibus Animalium* sayeth; that as well these as the haire of the eye-lids were created for defence. The eye-browes are as a penthouse to cast off the humors that fall from above: yea saith *Galen* in the 14. Chap. of his 11. Booke *de vsu part.* they are like a wall of defence which receiueth the first brunt of the irruption of any thing that would offend the eyes: which vse also *Cicero* maketh mention of in his second Booke *de Natura Deorum*.

It was not sufficient that the eyes should be walled about with bones, and as it were included or shut vp in bony dens, and defended by the eye-browes from those things which should fall from the forehead, because their forepart was exposed vnto many dangers. For being by nature made soft and tender for the more facile and easie reception of the species or formes of things outwardly directed vnto them, they must needs by diuers wayes be in danger of offence. Wherefore Nature very prouidently hath fenced them with ligaments and lids, wherewith as with lease-dores not only the eyes themselues but their whole orbes are shut vp, and thence it is that those creatures the outward skin or coate of whose eyes is notably hard, as *Galen* well obserued in his Booke *de instrumento olfactus*, haue no eye-lids at all, because their eyes were not so subiect to danger.

Of the eyes lids.

What creatures want eye-lids.

These lease-gates of the eyes are called by the Grecians *ὀφθαλμοὶ* *quasi τὸ βλέπειν* *οφθαλμός*, that is, *The Coats of the Sight*. Thence also they are not vnfitly called by a Poet *ὀφθαλμοφύλλα*, that is, *The leaues of the Eye*. *Cicero* calleth them *Palpebra*, either because in their sudden and frequent motions, they doe *Palpitare* that is tremble, or else because they are often subiect to a trembling weaknes. *Pliny* calls them *Gena*; *Festus* *Cilia*.

The names of the eye-lids.

The eye-lids are two in each eye, for it is cut through the middest and diuided into an vpper and a lower, for in both the corners they are manifestly continued. The vpper [*tab.*

1, and 3. E] in a man is much more mouable then the lower, which by some is thought to be immouable of it selfe and onely moued by the motion of the cheekes as *Archangelus* conceiueth. So *Galen* seemeth to say in the ninth Chapter of his tenth Booke *de usu partium*, but more plainly in the 10. Chapter and in his fourth Booke *de Locis affectis*, with whom also *Vesalius* consenteth and *Laurentius* yeeldeth a reason, for, saith he, what neede was there that the lower eye-lid should be moueable seeing by the motion of the vpper downward the eye is closed to his bottome, and by the motion thereof vpperward the eye againe is sufficiently opened? But *Platerus* thinketh that the lower eye-lid is moued something vpperward when we shut our eyes. And with him *Bauhine* is of opinion that the lower lid is moued by a Muscled, although his motion be farre more weake and lesse conspicuous then that of the vpper. For if both the eye-lids were made for the vse of the eyes then was it necessary that either the vpper should moue downward, or the lower vpperward, or the one meete the other. Now we finde by Dissection that in the lower lidde there is a semicircular Muscled as well as in the vpper, and in a creature aliue if we marke the eye well, we shall perceiue the lower lid to moue though not so manifestly as the vpper; but in Birds (as *Aristotle* obserued in the 13. Chapter of his second Booke *De Partibus Animal.*) the lower eye-lid is onely moued.

Neither could so sodaine and quicke motions come from the vpper lid alone, because the motion downward would haue needed a longer time then was fit for so quicke dispatch, and therefore they sooner meete if they ioyne to assist one another. But the vpper lid in a man and in those creatures in whom the lower is not so swiftly moued is larger, because it was to be let downe much further then the lower was to be raised vp. On the contrary in birds the lower lid is larger then the vpper.

The lower lid [*tab. 1. fig. 1, 3. F*] is much lesse then the vpper, and if it had not bene so little falling vpon it selfe it would haue bene corrugated, wrinkled or relaxed and haue falne from the eye. And which is more, the eye would haue become bleared, waterish and ill affected. Beside, many things might haue gathered therein which would haue hardly bene gotten out. Wherefore it was much fitter that this lower lid should be but little and sit close to the eye, that so whatsoever getteth within it might be better pressed out. Wee therefore resolute according to our sense, that both lids are moued, the vpper downward and the lower vpperward that they might meete one with another. But because the lower is by much the lesse, therefore is his motion weaker and more obscure, as the motion of the vpper is more eident because it is the larger.

These eye-lids are compounded of skin, the fleshy Membrane, a cote, Muscles, their brim, and the haire. Wherefore their substance is partly soft, partly hard. Soft as it is Membranous and Musculous, hard as it is gristly: for if (saith *Galen* in the sixt Chapter of his 10. Booke *de usu partium*) it had bene onely fleshy and soft, because they are first exposed to danger, they would haue bene sooner offended then the hornie coate of the eye, yea they would easily haue falne, become rugous and would not so equally haue bene stretched ouer all the parts of the eye.

On the contrary, if they had bene hard and bonie, they would not so easilie haue bene moued, neither could the hornie Membrane or coate haue touched them without danger of offence.

It was therefore fit that the eye-lid should bee made of such a substance as should both easily be moued and yet not offend the eye by contaction.

The Skinne of the eye-lid is the thinnest almost of the whole bodie altogether without fat, least thereby their motion should be hindred. Their fleshy Membrane is so thin that together with their Muscles it is scarce so thicke as the Membrane alone which is vnder the skinne in other parts, so that the orbicular Muscles seeme to bee nothing else then the fleshy Membrane distinguished with small Fleshy Fibres, as *Galen* saith of it in the ninth Chapter of his tenth Booke *de usu partium*. And by reason of this tenuitie or thinnesse of the Membrane and skin of the eie-lids, *Aristotle* saith, that their skin is without Flesh, and therefore if it be wounded will not ioyne together againe as it happeneth in the Prepuce or fore-skin of the yard.

The inner Membrane [*Table 1. Figure 5. ee*] which is produced from the *Pericranium* is exceeding thin and light. Thinner and lighter then the *Pericranium* it selfe, polished also that it should not hurt the sight of the eye which moueth immediatly against it. This membrane being produced into a length answerable to the length of the eye-liddes, as also into their

their skin, doth make in the vpper and lower part a round angle, and becommeth duplicated or doubled, to which duplication is annexed a certaine gristly substance harder then a membrane, which they call *τάρσος*, we called it before *the brim of the eye-lid*, and this substance shutteth vp and comprehendeth the duplication before spoken of. The vpper part of this membrane compasseth and as it were subdiuideth the inner superficies of both the lids. The other couereth the exterior roundnesse of the eye about the tendons of the muscles as farre as to the *Iris*, and producerh that coate of the eye which is called *Adnata* (for to it it is continued) [tab. 1. fig. 7. VV] which louingly ioyneth the lid vnto the eye.

Now the thinnesse and the lightnesse of the membranes was necessary to further swiftnesse and suddennesse of the motion of the eye-liddes; for if they had beene heauy they could neither haue beene moued suddenly nor often, which two things were very necessary: the frequency of the motion to meete with whatsoeuer might affect the eye, the celerity to take away all impediments of the sight. It is no wonder therefore if Nature made the body of the eye-lids very thin, smooth and soft, that so they might bee more nimble and prompt to moue at our pleasure.

The motions of both the eye-lids are vpperward and downeward, there is also another motion made by them both together which is circular, wherein both the eye-lids are gathered together. For it was necessary that the eyes should bee opened and shut, for if they had beene alwayes couered with the lid, they could neuer haue receiued the images of their obiects, and if they had alwayes remayned open, neither had they been free from outward iniuries, and beside they would soone haue growne weake by reason of the perpetuall dissipation of their inward light; wherefore it was of necessity they should bee opened and shut. And therefore *Aristotle* in the 13. Chapter of his second Book *de partibus Animalium*, writeth that this motion is by an instinct of Nature not after the guidance of our will, and that the Eyes by that instinct doe winke at any thing that falleth toward them; but this conceit *Galen* reprehendeth in the 9. Chapter of his 10. Booke *de vsu partium*, where hee saith, There are some Sophisters when they could not finde out either the muscles which moue the Eye-lids or the reason of their motion, they became so impudent as to deny that their motion depended vpon our will: but affirmed that it was Naturall like the motion of the arteries and of the heart, esteeming it better to teach a lye then to confesse their owne ignorance.

But this motion although it be voluntary yet it is partly free partly constrained: the free motion is for the couering and custody of the eyes, if haply any thing should be troublesome vnto them, as too strong a light, smoake, dust, a blow or whatsoeuer might happen vnto them from without. That motion we call Constrained which is stirred vp by a corporall affection or serueth thereunto, and this motion is exceeding suddain and swift, and therefore for the most part we do not marke it; whence it was that *Aristotle* rather thought it Naturall then voluntary; for example; when wee haue long time held our eyes open although there be nothing to offend them, yet we are constrained to close them vp or at least to wincke, and that oftner and more suddainly in winter then in Summer, when the winde blows then when the ayre is quiet: It may bee because the eye is not able to endure the touch of the externall ayre, because of the tendons of his muscles, which are of exquisite Sense and exposed almost naked to the aire, hauing nothing vpon them but the thin membrane called *adnata*; beside it hath beene often obserued that the ChrySTALLINE humour it selfe hath bin condensed or thickned with cold to the great detriment of the sight. Wherefore that the eye might not be hindered at all from seeing, nor from preservation of it selfe when neede doth require: the eye-lids were necessarily made with a sudden and swift motion to shut them and open them againe.

Now these motions are performed by two muscles commonly called the muscles of the Eye-lids: but *Archangelus* calleth them *musculi ocularyj*. Neither do others agree in the number of these muscles, for *Galen* and the ancients as also *Vesalius* and *Siluius* doe make two, diuiding the orbicular muscle of which we shall speake anon into two, whereof one, say they, lifteth the eye-lid vp the other depresseth it or moueth it downward. But the truth is, there is onely one muscle which shutteth the vpper lid according to *Columbus*, *Fallopious* and *Archangelus*. *Platerus*, *Bauhine* and *Aguapendens* affirme that that muscle contracteth both the lids. *Laurentius* indeed maketh this muscle double, and yet hee saith that both of them shutte the vpper lid. Hence it followeth that *Galen*, *Vesalius* and *Siluius* were ignorant of the muscle that openeth the eye, which *Fallopious*, *Platerus*, *Bauhine*, *Laurentius* and

The reason of the thinnesse of the lids.

The motions of the lids.

The necessity thereof.

Galen:

The motion double or of 2. kinds. Voluntary.

Constrained.

Aristotle excused.

How cold offends the eye.

The muscles of the eye-lids.

Diuers opinions concerning them.

Aquapendens will haue to be but one, but *Columbus* and *Archangelus* say there are two, the one of them we acknowledge, but that which they call the second we say mooueth the eye round.

The motions therefore of the eye-lids are performed by two muscles, the one *right* [tab. 1, M, tab. 2, B] of which *Galen*, *Vesalius* and *Siluius* were ignorant; and *Fallopins* ascribeth the inuention thereof to himselfe. This *right* muscle which listeth vp the vpper lid is situated within the cauity of the bones; in the vpper part of the Orbe, aboue but neare the muscle that listeth vp the eye it selfe, to which also it is in figure very like and fleshy, but lesse, and hath his originall from the same beginning with the other muscles that moue the eye: to wit backward at the hole of the opticke nerue. This muscle is extended directly to the vpper eye-lid, and is inserted with a broad tendon to the extremity of the lid, which we said was griftly and called *Tarsus*, and contracting his fibres inward draweth the lid vpward; the lower lid of his owne accord falleth downeward into his owne place, and so the eye is opened.

The second muscle which is semicircular [tab. 6, fig. 1, C E, tab. 1, K] or orbicular is called by *Columbus*, *Fallopins*, *Platerus* and *Archangelus* the first muscle of the eye lid, but *Vesalius* & *Siluius* following *Galen* haue diuided it into an vpper and a lower part. The vpper part, say they, listeth the lid vpward, the lower mooueth it downeward. *Fallopins* in his obseruations confesseth that he was a long time of the same opinion with *Galen* and *Vesalius*; but in the yeare 1553. tooke knowledge of his own error being admonished partly by *Oribasius* in his Booke *de dissectione musculorum* in what place he epitomiseth the 29. Chapter of *Galens* Booke; partly by dissecting the eye of a fish, called *Phoca*, which we call a Seale, which fish moueth both his eye-lids. *Laurentius* diuideth it into two, and calleth them the two muscles which shut the lids, whereof one, saith he, ariseth from the inward angle and compasseth the whole course of the hayres. The other ariseth from the same angle and the roote of the Nose, and is inserted into the *Tarsus* or brimme of the lid. But in the description hereof we will rather follow *Bauhine* who saith, That this orbicular muscle is seated betwixt the fleshy membrane and that which is produced from the *Pericranium* or Scull-skin. It is membranous and very thin or slender, yet a little increased by certaine circular and fleshy fibres which it borroweth from the fleshy membrane, & so standeth halfe round in eyther lid. It ariseth with a sharpe beginning at the roote of the Nose in the great and inward angle of the lower lid, where the common future is betwixt the head and the vpper Jaw, from thence it proceedeth all along the latitude or bredth of the lower lid, and is instantly enlarged and returned to the outward angle toward the vpper part of the Orbe, and passing on by the vpper lid is inserted with a sharpe determination into the vpper side of the inner angle, and so maketh an exact circle compassing the outward circumference of both the lids: yet *Fallopins* in his institutions excepteth the inner part at the great angle, from which it is prohibited that it might not be altogether circular.

The vse of this orbicular muscle is that being drawne toward his originall, it might at one and the same time mooue the vpper eye-lid downeward, and the lower vpward, and so ioine them and binde them both together. And that this is so it appeareth as well by the continuity of the fibres in the circumference and in the angle, as also by the motion of the same angle especially if it be a little more constrained, so as wee must needs winke something withall, for then it is perceiued manifestly both by the sight and by the touch. For nothing can be strikely drawne together and made to touch one another vnlesse some parts be drawne vpward and some downeward.

This muscle in respect of his fibres which are continuall, is most truely saide to bee one, but in respect of the two lids may be called two semicircular muscles, for being separated they make each of them a halfe circle, but being ioyned they make the circle perfect.

This muscle *Galen* knew, and in the 9. Chap. of his 10. Booke *de vsu part.* writeth that all the motions of the eye-lids are accomplished thereby. He diuideth it also into two, whereof one seated at the great angle draweth toward the nose, the other (saith he) is seated at the lesse angle and draweth toward the temples.

Moreouer in the traction of the first the lid is depressed; in the traction of the latter it is lifted vp, but because the fibres of this muscle are continuall through the whole lid it cannot be diuided.

Now in the lower lid although it also be moued vpward and downward, yet is there no Muscle which hath *right* motion, but only this forenamed orbicular muscle which draweth it

Bauhine's description of them.

The vse of the orbicular muscle.

How it is said to be double.

it indeed vpward, but rather toward the inner angle or corner, as it were to his beginning; as any man may perceiue by touching that part in himselfe, & yet I know that some thinke this motion proceedeth from the motion of the cheekes.

We determine therefore and conclude, that the motion of the eye-lids is accomplished by two muscles, one *right*, which being in the vpper lid eleuateth it, the other orbicular or round and is in both lids, which when it is stretched doth at the same time draw the lower lid vpwards and the vpper lid downward, and when there is need of a stronger contraction or closer shutting together, then also the orbicular muscle of the eye-browes (of which we made mention before) is drawne in to bee assistant, like as when wee would open the eye more staringly the muscles of the forehead doe much helpe vs.

He that would demonstrate these nice and curious Muscles must haue a very keene and small knife, wherewith hee must separate the skin, in the meane time taking care that hee doe not cut the Fibres of the Muscle, especially in the angles; then shall hee separate the Muscle below at the *Tarsus* or brimme of the lidde, and aboue in the bottome of the eye-brow.

Columbus and *Archangelus* add a third Muscle which proceedeth (say they) out of the same place with the muscle lifting vp the eye-lid, which third muscle is assistant vnto the former, because there is required more helpe to lift a heauie thing vpward then to draw it downeward. But we say that this third muscle of *Columbus* and *Archangelus* is indeede the sixt muscle of the eye.

Wee saide moreouer, that the substance of the eye-lids was cartilaginious or Gristly, hauing respect vnto their extremities or brimmes into which certaine semi-circular cartilages [tab. 1. a a] like the hornes of a halfe moone, round, small and softe are inserted betwixt the skin & the smal Membrane which compassed the lid. These the Grecians call *ταρσους*, but *Plinie* and the interpreter of *Galen* call them *Cilia*. *Hippocrates* in his Booke *de Viden-di acie* calleth this Cartilage *χονδριον*.

Their Vse beside that which we haue remembred before, is to helpe the motion of the eye-lids; for because they strengthen and firme the thin Membranes and hold them distended that they are not corrugated or wrinkled in their motion, it becommeth that the shutting and opening of the eye is equall.

Galen in his 9. Chapter of his 10. Booke *de usu partium* remembreth another vse of them which is also approoued by *Vesalius* and *Fallopins*, to wit, that the muscle which is in the vpper lid might haue a more firme and strong insertion. The same vse also it hath in respect of the haire of the eye-lids, which being established in so firme a substance doe remaine right and immoueable which otherwise would haue falne vpon the eyes. And therefore *Galen* in the seauenth Chapter of his 10. Booke *de usu partium* maketh this the second vse of the *Tarsus*, where he also affirmeth that it is perforated with many small holes which notwithstanding *Platerus* denieth.

The haire of the eye-lids [tab. 1. fig. 1. b b] are called by *Hippocrates* in *Coatis Rheopapises*, as also by *Aristotle*. *Plinie* calleth them *Palpebra à frequenti palpitacione*, because they are often rubbed. The later Anatomists call them *Cilia quod oculos celent*, because they hide the eyes. They are borne with vs into the world, as are also the haire of the eye-browes and disposed in an elegant order, keeping an equall magnitude and number, I say an equall magnitude: for saith *Galen* in the 14. Chapter of his 11. Booke *de usu partium*, if you add any thing to them, or take any thing from them you corrupt or vitiare their Vse, for if they bee fewer or slenderer there may some-thing fall through them to offend the Eye.

Againe, if they be thicker or grosser, they are no more a wall or defence to the eye, but a prison wherein the apple of the eye is hid and obscured, which of all the Instruments of our senses hath least neede of such an obstacle, and therefore saith *Galen* in the place before quoted, our wise Creator hath laide vpon them a law of necessity to keepe continually an equall magnitude, because hee saw it was most fit so to bee for the vse of that member for which they were ordained.

But whereas (and this is *Galen's* obseruation in the 7. Chapter of his 10. Booke *de usu partium*) it was most conuenient that the haire of the eye-browes should couch or fall one vpon another, because they were made to receiue that which fell from the Head before it could come into the eye: these haire of the eye-lids hauing no other vse were made to stand straight, because they should better hinder dust, flies, or any such like things from falling into the eyes.

Againe,

How the lower Lid is moued vpward.
The conclusion concerning the Muscles of the eye-lids.

Of the gristle of the eye-lids called Tarsus.

Their vses.

The haire of the Eye-lids. Their names.

Proportion.

The wisdom of God.

The maner of their position

And reason
thereof.

Againe, they stand not streight vpward to the browes nor directly downeward to the cheekes, neyther do they bend inward to the eye; for if they had stood streight vpwarde their vse had beene forfeited for which they were created, and if they had stood directly downward or beene bent inward, they would haue beene a great hinderance to the sight by breaking the continuity of the visible objects. Notwithstanding as the haire of the vpper lid are bent a little vpward, so are those of the neather lid curued downward, for if they had stood straight out they would haue cast a shadow vpon the eyes and hindered our looking vpward.

Their distance

In like manner there is a conuenient and as it were measured distance betwixt haire and haire: for if they had bin set one far from another many thing might haue falne betweene them which now are intercepted, and if they had touched one another they would haue cast too dull a shadow before the sight. All which the wisdom and prouidence of our great Creator hath by this excellent order and position auoyded. These haire doe neuer grow too long, neyther do they euer fall, vnlesse it be in extreame diseases of that part, although *Aristotle* in the 11. Chap. of his third Booke *de Historia Animalium*, hath a conceite that the vse of *Venus*, especially if it be frequent will make them fall.

Their vses.

Neyther do these haire serue onely for ornament as some haue conceyued, but also to direct the visible spirits and the beames which shoote forth from the inner parts of the eye, for if they be falne away or retorted, a man can neyther see so directly forward, nor so farre off.

Againe, their often twinkling recreates the sight, & breaketh also somewhat the brightness of the object, as well as they intercept those things which otherwise would fall into the eye, being placed as a Net to catch any thing that would rush into them.

Their vessels.

These eye-lids also haue veines from the Iugular veines; and Arteries from the *soporary* or sleepey Arteries, Nerues also from the second coniugation, al which vessels do leade vnto them nourishment, heate and motion.

The bladders
aboue and vnder
the eyes.

That partice which hangeth ouer the vpper eye-lid [tab. 1. fig. 1, 2. g] *Ruffus* the Ephesian calleth *κοίλον*, that is, the hollow: and that which answereth thereto vnder the lower lid is called *υποκοίλον*, or vnder the hollow. [tab. 1. fig. 1, 2. h] And this vseth to swell in the Dropsie, the greene sicknesse, a long fluxe of the *Hæmorrhoides* and of the courses, sometime also when the eye begin to be bleared.

The vses of
the eye-lids,
Aristotle.

It remaineth now that we add a word or two concerning the vse of the eye-lids. Although *Aristotle* in the 13. Chapter of his second Booke *de partibus Animalium* acknowledgeth no other vse of these eye-lids, but onely to couer the eyes, and intercept those things which would fall into them: and therefore saith that fishes haue no eye lids, because they are alwayes in the water: nor shelly creatures because the Membrane of their eye is very hard, and beside they stand deepe in their sockets, yet we haue learned many other vses of them which we will acquaint you with.

Varolinus.
The first vse.

The first and chiefe vse of the eye-lids therefore is, as *Varolinus* well obserueth, to cleanse the hornie Membrane from droffe, for the sight requireth an exact puritie in *medio diaphano* that is, in his *tralucent meane*, otherwise wee cannot see especially so distinctly, as appeareth in troubled water and smokie ayre: wherefore because the hornie coate by reason of the moisture which sweateth out of the glandule, as also by reason of the contaction of the outward ayre is easily obtenebrated or darkned: the eye-lid was made compassed, that at once it might touch the whole eye, and therefore in opening the eye when the lid is lift vp, it sweepeth and as it were polisheth the whole horny coate or Membrane; and this is the reason why when we desire to view a thing curiously we often winke with our eye-lids.

The second.

The second vse of the lids is, that the visible vertue might sometimes be turned from the light, especially in sleepe that a man might take the better rest; and hence it is that in those creatures which want eye-lids, as Locusts, Lobsters, Crabs, and such like insectiles, nature hath provided certaine cauities, whereinto in the time of their repose as into certaine chambers they receiue their whole eyes and shoote them out againe when they looke abroad, for she hath an especial care of this, that euery sense should be kept fit to performe his owne action.

And hence we may imagine the vnnaturall and cruell punishment which the *Carthaginians* inflicted vpon *M. Atilius Regulus*, whom in the first Punicke warre they had at vnawares surprized, who being by them sent to *Rome* (after he had before taken his Oath

to

to returne) did in the Senate-house dissuade them from making exchange of captiues, wherefore when hee returned they cut off his eye-lids and set him in the sunne vntill the brightnesse of the object ouer-came not onely the spirits of his Eyes, but also of his life.

A third vse of the eye-lids is to recreate the sight, least at one time too great number of spirits should be exhausted; for if the eyes should be so long open as wee are awake, they would be wearied, and many things falling vpon their coates would offend them. Againe, if they bee not quite shut vp they direct our sight, if wee desire to take a true ayme at any thing which is somewhat farre off.

Finally, they serue to defend the soft eyes from the incursion of outward iniuries, because it is much better sometimes not to see at all, then by offering to see, suffer our eyes to be offended. And thus much concerning the circumstances of the Eyes. Now we proceede vnto the Eye it selfe.

CHAP. IIII.

Of the Fat and Muscles of the Eyes.

THe parts whereof the Eye consisteth, are five, Fat, Muscles, Vessels, Coates and Humors. The Fat which Anatomists do some of them call *Adeps*, some of them *Pinguedo*, is very plentifull about the eyes [*tab. 1. Fig. 6. T*] especially it is found in those spaces which are betwixt the Muscles and the Nerues. It is also more plentifull at the vpper Muscle, because that is greater and ordained for more frequent and strong motions. In like manner toward the lower side of the Orbe there is plenty of fat, which like a pillowe is laide vnder the Eyes, that with their weight they should not presse themselves vpon the bones. Againe, betwixt the Muscles and the globe of the eye there is abundant fat, that when the Muscles worke the eye should not suffer compression. Finally, there is also fat found neere the Veines and Arteries, whereby the vessels are smeared ouer and their distention preuented in the motion of the eyes.

The vse of the fat, in as much as it is warme, is to heate the eye which by nature is waterish and cold, and beside to defend it from the coldnesse of the outward ayre. And that is the reason why wee neuer feelee any manifest coldnesse or stiffenesse in our eyes. Againe, the humidity of the fat doth moysten the Muscles, that they become not exiccated or dried vp in their often motions. The softnesse of the fat keepeth the eyes from being offended by the bones about them. The vntuosity or oylie fatnesse maketh their motion swift and facile, and beside, when the Muscles are somewhat dried, because of their motion and as it were consumed, it affoordeth Aliment vnto them.

The Muscles of the Eyes, although they belong to another place, namely to the Booke of the Muscles, yet because we are desirous to absolue the History of the Senses in this present Booke, we wil take liberty to vary something from our scope and set downe as perfect a description of them heere as we can. And that was the reason why before wee were so large in describing the Muscles of the eye browes and eye-lids, concerning all which we will spare our labour and yours when wee come to the History of the Muscles. Because therefore our eyes were giuen vs as spies and scout-watches that wee might pursue things profitable and eschew that that is hurtfull, Nature made not the eyes immouable, for then they should haue discerned onely that which is opposite vnto them, for so saith *Aristotle* in his second Booke *de partibus Animalium* and the 10. Chapter, *Cernimus per directum*, that is, we see by a straight line; not in euery position saith *Galen* in the eight Chapter of his tenth Booke *de vsu partium*, because oblique, side, backward, higher and lower Objects do not fall in with the ball of the Eye. Nature therefore hath so disposed the Eyes that they moue and returne themselves on euery side at their pleasure. But *Galen* addeth in the place before quoted, that not onely the eyes are moued but also the necke and the head are made moouable for the behoof of the eyes, because there are six positions of place vnto al which the eye ought to moue; that is to say, vpward downeward, foreward backward, on the right and on the left.

It was therefore of necessity that the eyes should haue other helps beside their owne motion,

The third vse.

The parts whereof the eye is compounded.

In what places of the eye the fat is found.

The vses of the fat.

Why the muscles of the eye are described in this place.

We see by right line.

tion, for the eyes are not mooued forward and backward, partly because there was no absolute necessity, and partly because it was impossible; it was not necessary they should moue forward saith *Aquapendens*, because the eye doth not attaine vnto the light but the light vnto the eye, which in a moment enlightheth an infinite space euen vnto the eye, yea inlinuateth it selfe thereinto.

But the wise Creator hath made a mends for the defect of this motion of the eyes by the helpe of the motion of the head, which out of hand conuerteth it selfe to see those things which the eye could not by his proper motions perceiue. Moreover, that wee might see whatsoeuer is behind our backe (which could not be done onely by the circumuolutions of the head) Nature hath so prouided that the thighes can carry the body round. In like manner the motion of the eye vpward is assisted by the backward motion of the head and of the whole spine, which they haue experience of that strue to tak view of the pinnacle of a high Steeple: so also the motion of the eye downeward is furthered by that motion of the head and of the necke which is forward.

Seeing therefore it was necessary that the eyes should bee moued with voluntary motion; and all voluntary motion is made by muscles, therefore our wise Creator hath given vnto them diuers muscles whereby their motions are very sudden and expedite. Hence it is that *Aristotle* in the eight Probleme of the seuenth Section calleth the Eye *The most noble part of the body*: yet saith he, the left eye is more nimble then the right. Now whereas the motions of a mans eye are fixe according to *Galen* in the third Chapter of his first Book *de motu musculorum*, it followeth necessarily that the eye must haue fixe muscles; but *Galen*, *Vesalius* and the rest of the Anatomists as *Columbus* sayth, being accustomed onely to describe the eyes of beasts haue added a seauenth muscle, and those fixe also which they haue described they haue misplaced. But wee are to describe the muscles of the eye of a man, that seauenth which belongeth to beasts is deuided into two, into three, and sometimes into foure.

In men therefore as wee haue said there are fixe muscles according vnto the fixe motions of a mans eye, foure of which motions are *Right*, that is to say vpward, downeward, to the right hand and to the left; the two motions remayning are oblique, to which belong two oblique muscles whose vse is to rowle the eye about. Notwithstanding one of these is exactly *oblique*, the other partly *right* partly *oblique*. All these muscles are seated on the backside of the Eye within the cavity of the Scull, whither they accompany the opticke nerue and so remayning in their position, the eye and they together doe make a Pyramidal or turbinated figure. [table 1. figure 6, 7.] Among these muscles the thicker and more corpulent are the *Right* which haue all the same structure, originall and insertion, and do passe straight all along the length of the eye; the oblique muscles are lesse fleshy, yet very like one another.

All these muscles of the eye are small that they might be sooner mooued; but that which helpeth most the volubility of their motion is the round figure, which is the nimblest of all others, as we may perceiue by the roundnes of the heauens.

The eye therefore being round as are also the muscles thereof, is euen in a moment conveyed ouer the whole heauen, and the head it selfe is therefore mooued very suddainly and swiftly, because it toucheth vpon the bone whereon it resteth with a narrow point.

The foure *Right* muscles meeting and touching one another toward the roote of the nerue optick, doe arise with a sharp beginning from the lower part of the bony orbe which is made by the wedge bone, hard by the passage through which the nerue of sight or the opticke nerue doth yssue. I know well that *Vesalius* is of opinion that they arise out of diuers parts and into diuers parts are inserted. Againe for their matter, he conceiueth they arise from a commixture of the *Dura mater* which compasseth the optick nerue and a nerue of the second coniugation. *Platerus* thinks that they arise from the membrane which compasseth the orbe of the eye, and that membrane which inuesteth the opticke nerue. *Aquapendens* imagineth they proceed from the *Pericranium* or Scull-skinne. *Laurentius* disputeth about their originall on this manner; They erre, saith he, which thinke the muscles of the eye doe arise from the inner thicke membrane which compasseth the opticke nerue, for this is altogether against sence; they could not, saith he, arise from a membrane nor they ought not. They ought not, because a membrane of an exquisite sence compasseth the nerue, which nerue the muscles in their motions would compresse, and so the sight would bee offended. They could not because they are not established vpon a firme foundation.

TABVLA II.

A, The eye lid.

B, the Tarsus or gristle where the haire grow.

C, the muscle lifting vp the eye lid.

D 1, 3, 4, the right upper muscle of the eye in 3, and 4 with the nerve.

E 2, 3, 4, the right lower muscle of the eye, in 3, and 4 with the nerve.

F 1, 2, 3, 4, the right externall muscle of the eye.

G 1, 2, 3, 4, the right internall muscle of the eye.

H 1, 2, 3, 4, the oblique superior muscle or the pulley, whose tendon is marked with a and the pulley with b.

I 2, 3, 4, the oblique inferior muscle of the eye.

K 1, 3, the opticke nerve.

a 1, 2, the tendon of the oblique superior muscle.

b 1, 2, the sayd pulley, a small gristle where-through the tendon doth passe, and in the 3 and 4 pulled from the bone.

c c c c c 3, 4, the moving nerves of the eyes.

a b 5, the second muscle of the eye lid lying in the cavity of the eye, whose broad tendon b is inserted into the eye lid.

y 5, the haire of the eye-browes.

d e 5, two right muscles leading the eye vpward and downeward.

z u 5, two right muscles moouing vnto the right and left side. B 1, 5, two oblique muscles lightly turning the eye. x 5, the seauenth muscle which may be deuided into more. l 5, the Opticke nerve.

It remaineth therefore, saith *Laurentius*, that they must arise from the inmost depth of the orbe or cavity. But we rest vpon *Bauhins* opinion for their originall.

Their whole bodies throughout their whole course are fleshy, and their bellies beare out round as they come forward. But they determine a little about the middle of the eye into a broad thinne and membranous tendon wherewith they compasse the whole eye before, and grow very strongly to the horny Tunicle neare vnto the Iris or Raine-bow in the greater circle: and these tendons ioyned together doe make that nameles coate of *Columbus* and white of the eye.

For wee conceiue that this whitenesse is caused rather by the tendons of these muscles then that it properly belongeth to the coate which we call *Adnata*. And so much shall bee sufficient to haue spoken in generall of the muscles of the Eye. Now wee come to a more particular description of them one by one.

The first [*tab. 2. fig. 1, 3, 4. D fig. 5. d*] which is the third according to *Vesalius*, and *Galen* also in the 8. Chapter of his 10. Book *de usu partium*, is seated aboue; fleshy it is and round, thicker also then the rest, greater and stronger then the second, because it lifteth the eye vpward toward the brow. For there is greater strength required to lift a thing vp, then to pull it downe. The names of this muscle commonly given by Authors are, *Attollens* and *Superbus*, the *Lifter* and the *Proud* muscle.

Their inserti-
on.

Whence the
whitenesse of
the eye proceedeth.

A more parti-
cular descrip-
tion of the se-
uerall muscles.

The

The second which according to *Galen* and *Vesalius* is the fourth [Table 2. Figure 2, 3, 4. E. figure 5. 1] is opposite vnto the former and placed in the lower part; it draweth the eye downeward to the Cheeks, and therefore needed not bee so great as the former, because the eye declineth easily with his owne waight. It is called *Deprimens* and *Humilis*; the *Depressor* and *Humble* Muscle.

The third [tab. 2. fig. 1, 2, 3, 4 G. fig. 5, 2] according to *Galen* and *Vesalius* the first, is seated in the great angle and leadeth the eye inward toward the nose, and is called *Adducens* and *Bibitorius*, we may call it the Gleeing Muscle.

The fourth [tab. 2. fig. 1, 2, 3, 4 F. Figure 5. 1] which according to *Galen* and *Vesalius* is the second, is opposite to the third, seated on the outside of the eye which it draweth to the lesser angle or to the temples, and is called *Abducens* and *Indignatorius*, we may call it the Scu-muscle or the Muscle of Disdaine.

Their Vse.

If all these foure worke together, the eye is drawne inwarde, fixed, established and contained, which kinde of motion Physitians call *Motus Tonicus*, wee in our Language call it a Set or wist-look. *Archangelus* is more distinct in the assignation of the motions of these Muscles, for (saith hee) when as at diuers times they are moued with any pause betwixt their motion, then the eye is mooued toward the originall of that Muscle which worketh. But when they are mooued at diuers times without any pause, that is, with immediate successe motions, then they mooue the eye round: but when they all mooue in the same moment, then do they set fixe and establish the Eye immooueable, wherein they are holpen by the fift Muscle, whether all foure doe mooue apart or do worke together.

The fifth [Table 2, Figure 2, 3, 4. 1, Figure 5. B] which is also according to *Galen* and *Vesalius* the fift, but the sixth according to *Fallopins*, *Platerus*, and *Laurentius*; is seated in the outside at the depth of the cavity and ariseth betweene the eye and the Tendons of the second and fourth Muscles; which is the reason why some haue thought that it taketh his originall from the Eye and is againe inserted into the same. But the very place of his originall is at that cleft which appeareth like a future or seame of that bone of the lower part of the Orbe which ioyneth the first bone of the iaw with the fourth. Sometimes it ariseth with a fleshy beginning from a bony scarfe. It is slender, round, short and exactly oblique, and passeth obliquely toward the outwarde angle as it were to embrace the Eye, and is implanted with a short and round Tendon, degenerating into a thinne and Nervous termination neere vnto the *Iris* or Brain-bow but obliquely, hard by the insertion of the sixt Muscle, so that sometimes the Tendons of them both, serue one and the same.

To recite heere the contentions and challenges of Anatomistes about this Muscle would rather entangle our Readers minde then giue him any great satisfaction, especially seeing those learned men to whom so nice disquisitions will not seeme tedious, may repaire to those fountaines from whence we haue drawne our by-streame, and therefore wee passe on to the vse which is by the contraction of his Fibres to rowle the eye obliquely downeward to the outward angle.

His originall.

The sixt [Table 2. figure 1, 2, 3, 4. H. figure 5. 1] which is the sixt also according to *Galen* and *Vesalius*, but the fift according to *Fallopins*, *Platerus* and *Laurentius*, is seated on the inside and the vpper part, yet vnder the right Muscles, and is partly right and partly oblique. It ariseth from the same place with that Muscle which draweth the eye directly vnto the inner angle at the side of the Opticke Nerves passage, which is in the very depth of the Orbe.

His end or Tendon.

It endeth as well in man as in brute beasts into a round, small and long Tendon, [table 2. fig. 1, 2. 4] almost at the vtmost brimme or edge of the inward angle. This Tendon is reflected through a smal gristle hollowed like a Cane and scituated in the greater angle, which *Fallopins* first of all men called *Trochlea* or the Pulley, and thence proceeding obliquely to the right angle [tab. 2. fig. 2, b. but in the third and fourth figure it is shiuen from the bone] toward the vpper part of the eye, it is inserted betweene the first and the fifth Muscles with an oblique line, all which time the foresaid Tendon is compassed about with a certaine Ligament as it were with a sheath.

His progresse. *Fallopins* his *Trochlea* or pulley.

His insertion.

This Muscle being drawne inward toward his originall with his Tendon hee turneth the eye in a circular motion to the inward Angle. These two turning Muscles the one vpper the other lower, are called *Circulares* & *Amatorij*, the rowling or glauncing Mus-

Muscles, some also call the sixt *Musculum Trochlea*, or the Muscle of the pulley.

The seauenth Muscle which is for the most part found in brute beasts, excepting the Ape and Fishes, is placed [tab. 2. fig. 5. *] vnder the former fixe, and hath of it selfe that figure which the former fixe do together make. It is short and compasseth round about the Opticke nerue, [Tab. 2. fig. 5. A] yet is there some fat betweene them. Proceeding forward it is dilated and embraceth the whole globe of the eye euen to the roote. It maketh also a circle like as the foure first did at the *Rainbow* make a circle with their chords or Tendons: at his insertion, which is into the hard tunicle of the eye, it becometh fleshy and may be diuided into three or foure; so as *Galen* in the fourth Chap. of his fift Booke *de dissectione Musculorum* maketh a doubt whether it be one Muscle, or double or treble.

The vse of this Muscle is to tie vp and strengthen the eyes of brute beastes hanging alwayes downward, that they should not fall with their owne weight. It also incompasseth the nerue Opticke thereby making his passage, not onely straight but also warranteth it from distention and from leaning against the bone in violent concussions or suddain motions. *Galen* addeth in the booke before named, that in that motion which we called *Tonicall* or the fixing of the eye; it establisheth the same when we would accurately discerne any small body: for he supposed this Muscle also to be in men.

But Nature or the God of Nature rather, did not see it needfull for mankinde, because his countenance is erected vp to heaven, & if at any time he be constrained to looke downward, he hath all the foure right Muscles with their ioynt strength to sustaine his eye, because their Fibres grow to the Membrane which compasseth the Orbe.

Fallopini addeth an eight Muscle found in Oxen which draweth that gristly Membrane which *Aristotle* in the 12. Chap. of his second Booke *de Historia Animalium* calleth the *skin of the angle*, with which Membrane brute beasts do blinke when they feare lest any thing should fall into their eyes: vnlesse any man shall thinke this is a part of that Muscle which draweth the eye to the outward angle.

To finde out these Muscles of the eye, when the Braine is taken away you must cut the Orbe at each corner euen to the Opticke nerue with a saw, hauing a great care lest the Trochlea or pulley which is in the inner angle be offended.

Next you must separate the *Pericranium* from the bone, and bend the vpper part of the Orbe backward, then take away the fat, and so shall you perceiue the Muscles of the eyelids, and of the eyes themselues together with their vessels; and if you would obserue the proper and peculiar motion of euery Muscle, you must preserue them in their proper positions and tie to euery one of them a thred not farre from the Tendons, then draw the thred and the draught thereof will describe vnto you the vse of the Muscle to which it is tied.

You may also take the eye whole out of his Orbe together with the Trochlea, which is in the inner angle, and so demonstrate what you please. And thus much shall be sufficient to haue spoken of the Muscles of the eyes. Now we proceede vnto their vessels.

CHAP. V.

Of the vessels of the Eyes.

Of the same reason for which we intreated precisely of the Muscles of the eye in their History, we will also handle their vessels more distictly in this place, and passe them ouer more lightly in the booke of Vessels.

The vessels therefore which are sent vnto the eye are veines and Arteries, to which are added Nerues, as being common Organs no lesse then the other. The Veines which are sent vnto the eye proceed out of the iugular Veines and leade blood for their nourishment.

The Arteries arise from the *Carotides* or sleepey Arteries, and are disperfed through the muscles to strengthen the inward heate, and to sustaine their life; through which Muscles as also through the fat they are accompanied with Nerues, and distributed through their Membranes, which is shewed in the third Table the second and third figures at *b*.

The Nerues are of two sorts, *Optici* & *Motorij*, that is, *seeing* & *moouing*; they proceed out of the marrow of the braine yet remaining within the scull and making the spinal marrow.

The Opticke Nerue [tab. 2. fig. 1. and 3. K, fig. 5. A, tab. 3. fig. 2, 4, 8. a.] which is called *Visorius* or the Nerue of sight, is on each side one, and these are amongst al the nerues of sense the largest, the thickest, the softest, and *Galen* also saith the longest in the third Chapter of the 16. Booke *de vsu part.* They are of a rare texture compassed with both the Meninges. [tab. 3. fig. 2, a b c] They are the greatest and thickest of all the Synewes, that so abundant

Where yni-
ted.

The vses of
their coniun-
ction.

The vse of the
optick nerues.

They are very soft saith *Galen* in the fift Chapter of his seuenth Booke *de placitis*, that they might be sooner affected because they are nerues of sense and a sense so very necessary, for al sense is perfected by receiuing and suffering. They are softer then any other, because they are affected by the light alone, which they receiue also very much broken. They are the longest of all the rest, because the way is long from their originall to the Orbe of the eye. Their texture is rare and thin, and therefore *Herophilus* beleueed that they were perforated: and *Galen* thereupon called them *meatus visorios*. For in the third Chapter of his 16. Booke *de usu partium*, hee noteth out of *Herophilus*, that they are in their inside perforated all along their passage, and that perforation was the reason why they were made so large.

By these *Galen* thinketh not onely that the faculty of sense is transported, but also the Anima spirits in which the faculty is established, that so their sense might be more abundant and strong: whereas through other Nerues he conceiueth that the vertue or faculty onely is carryed as we may perceiue in the 12. Chapter of his tenth Booke *de usu partium*, and in the fifth Chapter of his 7. Booke *de placitis*. These Opticke nerues in their end and in their originall are distinct, but at the middle of their progresse about the saddle or seate of the wedge bone, before they fall out of the scull becoming a little broader, the right is vnited with the left [*tab. 21. lib. 7. fig. 1. G G*] so that they make the forme of the Greeke χ . not by cleauing the one to the other, or by intercussation, or that one rideth ouer the other, but by perfect and absolute vnion & confusion of their marrows they are so ioyned that one cannot be separated from the other, [*tab. 21. lib. 7. fig. 1. H*] for it is a very rare thing in Anatomie to find them separated.

The vse of this coniunction is, partly that the *Pupilla* or sight of the eye might look vpon the same plaine least otherwise the visible objects should appeare double because the eyes are double: partly that the *Idea* or formes of visible things might be vnited and so the faculty of sight be common to both sides, because the visible spirit may passe from one eye to another in a moment for the more certainty of the sight: And this is prooued if we presse or inforce one eye vpward or downward, for then all things appeare double: wherefore as it was conuenient that the eyes should be paralels; so also the nerues, which because of the motion of the eyes might decline from the right line, especially seeing the muscles do compasse them and cleaue vnto them: for when one muscle onely whether it be the vpper or the lower is moued, the eye also is rowled to one side. And therefore Nature hath worthily ioyned the Opticke nerues together, that euen in such motions the faculty might be wholly conuayed to eyther side. And this appeareth to be true because if you put your hand betwixt your eyes along the length of your Nose, so that you cannot see the object you intend with both eyes, you shall perceiue that you see more obscurely on either side, then if you looke vpon the object with one eye shut vp, for then the faculty which was before dispersed vnto both, is vnited into one. Adde also this third profit of the coniunction, that the soft nerues hauing a long way to go, might thus bee made strong and established, because Nature could not sustaine them with any ties or knots of Membranes. After their coniunction, they are instantly disioyned, and each nerue issueth through his proper hole which is framed in the depth of the Orbe out of the scull [*tab. 21. lib. 7. figure 1. above H*] and so the right attaineth to the right, and the left vnto the left eye, and there are implanted.

In a man they are inserted on the backside into the center of the horny coate [*see the third tab. fig. 2, 3, 4, 8.*] because onely man can looke directly forward. In brute beasts as in oxen and horses, whose eyes are much farther asunder, they attain by a line notably oblique vnto the compasse of the eye and do not determine in the Center. Hence it is that the eyes of brute beasts doe see the earth on eyther sides to direct their gate and to finde out their nourishment. These Opticke nerues when they are come vnto the eyes are dilated saith *Galen* in the 1. Chap. of his 10. Booke *de usu partium* and like a membrane each of them incom- passe the glassie humour; *Galen* also addeth in the same place that they are inserted into the Christalline humour.

The vse of these Opticke nerues is to leade the visible faculty from the braine, which in the eyes is gathered vnto the visible formes, where the Nerue is dilated into the Membranes of the eye. For if this Nerue be obstructed as it is in that disease which the Arabians call

cal *Gutta serena* the cleare drop, the action of seeing is altogether taken away or intercepted. And so much concerning the Opticke Nerves.

Gutta serena.

The Nerves of Motion are on either side one, which sendeth a small surcle to each Muscle by which it is mooued [*tab. 2. fig. 3, 4. sheweth this*] (as he may perceiue who diligently shall separate the Originall of the Muscles from the Nerue) which also is spread abroad into the Membranes. These moouing Nerves in their originall are continuall, that is, the right is ioyned with the left; whence it commeth to passe that when one eye is mooued the other also followeth the same motion; for they proceede ioyntly out of one point as it were in the fore-part of the spinall Marrow, so that the same object and the same light, after the same manner and at the same time insinuateth it selfe into either eye, that the sense and discerning might be one and the same; and this maketh much to the perfection of the sense that one and the same thing might not appeare double, which doubtlesse would happen if one eye might be mooued vpward and the other downward at the same time. That this is true you may easily learne if with your finger you either depresse or lift vp one of your eyes, for then all objects will appeare double, one higher another lower. But if you mooue your eye toward the side, because the *pupille* or *Sights* are in the same line, the objects will not seeme double. Wherefore *Galen* in the 13. Chapter of his 10. Book *de usu partium* writeth, that the Diameters of the visible Cones must bee placed in one and the same plaine, least that which is one do appeare double.

The Nerves of motion.

Where they are continuall.

Demonstrations hereof.

Hence it is, that in the palsy and convulsion of the Muscles of the eye the patient often seeth double Objects, because the eyes do depart from the same plaine. So also when the Opticke Nerves are either conuelled or relaxed the *pupilla* or *Sight* not beeing in the same line, all things appeare double, which also for the same cause happeneth oftentimes to men when they are drunke.

From these Instruments Veynes, Arteries and Nerves are deriued vnto the eye abundance of Spirits Naturall, Vitall and Animall, which are properly called visible spirits: wherefore according to the plenty of the Spirits conteyned in the eyes, their magnitude as also their splendor or brightnes is greater or lesse. And hence it is that when men are nere their death their eyes become little, languid and obscure, as also those that do too much follow veneriall combats haue their eyes small and extenuated, so also we see that in living men the eyes are full and turgid, but when they are dead, they become lesse as also laxe and rugous, for the presence and absence of the spirits maketh a difference betwixt a living and a dead eye.

The spirits of the Eyes.

Againe, according to the diuers disposition of the spirits and of the eyes from them, we are able by our sight to distinguish and iudge oftentimes of the affections of the mind, which is a cleare argument and euen liable to our sense, that the body of a man is full of spirits, which thing *Galen* also in the 10. Booke *de usu partium* prooueth by an elegant and demonstratiue argument. For (saith hee) if vpon the closing of one eye you do attentiuely marke the *pupilla* or sight of the other, you shall perceiue it in a very moment to be dilated, because a greater quantity of spirits doth fall into the Grapic coate which wee call *Vnea*, through that coate which is called *Reticularis* or the Nette, where they dilate the hole of the *Vnea*, which hole is properly called *Pupilla* or the sight and Apple of the eye. Finally, that the eyes are full of spirits is hence conuined, because they are sometimes obscure, dull and languid or weake, sometimes bright or shining, quicke and apprehensue. But least these spirits which are of an admirable finenesse and subtilty might exhale or euaporate they are kept in and retained by a thicke, thight and strong Membrane which is called the Horny coate.

Diuers arguments to proue there are spirits in them.

CHAP. VI.

Of the Membrane of the Eyes.

¶ Auing declared the muscles and the vessels of the eyes and now remooued them away, the eye it selfe round like a bowle appeareth [*table 2. fig. 3, and 4. table 4 fig. 2, and 3.*] which may be compared to an egge, both for the figure and construction. To an Egge I say which consisteth of Membranes, the shell which is an indurated Membrane and a thin Membrane vnder it, and humors, the white and the yolke: So the globe

The eye compared to an Egge.

of the eye hath membranes and humors. Membranes that being of a watery nature it might better be contained in his position and the humors by them encompassed, which membranes had need to haue a more solid substance, beside they are a great furtherance to the sight: Humors onely for the sight.

The Membranes of the eye.

Their number very diuerse according to authors.

Concerning the number of the Membranes the authors are at great difference. *Hippocrates* in his Booke *de Locis in Homine* acknowledgeth but three, the vppermost thicke, the middlemost thinner, and the third thinnest of all which containeth the humors; but in his Booke *De Carn.* he saith they are many. The later Grecians reckon foure, *Siluius* siue, *Vesalius* fixe, *Galen* in the 7. Chap. of his 10. Booke *de vsu partium* seuen; vnto whom *Fuchsius* and *Aquapendens* do consent. Wee will diuide them into two kinds, some are common to the whole eye, some are proper to the humors; the common Membranes are the *Cornea* and the *Vnea* the horny and the grapy coates. The proper Membranes are those with conteyne the Christalline and the glassie humors. But whereas there are commonly reckoned seauen, *Adnata*, *Cornea*, *Dura*, *Vnea*, *Choroides*, *Aranea*, and *Retina*, whereto some haue added those which are called *Vitrea* and *Innominata*, we will run thorough them all after our Anatomical order.

First *Adnata*.

The first is called *Adnata* which is the 7. according to *Galen* in the second Chap. of his 10. Booke *de vsu part.* so called as it were *Nata circa oculum*, bred about the eye. *Galen* calles it *επιεσφυον*, because it cleaueth on the outside of the other membranes of the eye, whereupon it is also called *Adherens* or the cleauing Membrane. This is the vtmost. *Aquapendens* supposeth that it ariseth from the *Periostium* & tendons or chords of the Muscles. It first offereth it selfe before Dissection together with the transparant part of the horny Membrane lying vpon the white thereof.

Whence cometh the white of the eye.

The *Periostium* is alwayes next vnto the bone, vnlesse it be where it produceth the eyelid, for hauing thereto attained it maketh an angle and so is doubled, one part of which duplication compasseth the lid of the eye, the other part [tab. 1. fig. 6, 7, 8, V] maketh this *Adnata* or adhering Membrane, which becomming thinner in the fore-part onely where the white of the eye appeareth, couereth the same and determineth or endeth in the greater circle of the *Iris* or *Rain-bow*, where it is continued with the horny Membrane. [tab. 1. fig. 7, 8, V. and tab. 3. fig. 1. d]

Coniunctiua.

It is said to be white from the colour, although saith *Aquapendens* it be not indeed white but onely appeareth so, because the Tendons of the Muscles lying vnder it do represent a kind of whitenesse. But *Hippocrates* in *Coacis* calleth it λευκον, the white of the eye. It is a smooth Membrane, and by interposition thereof the eye is fastned to the orbe and to the inner bones, and it serueth instead of a Ligament to all the bones about the eye. Hence it is called commonly *Coniunctiua* a *Coniungendo*, because it ioyneth together al the Membranes of the eye, thereby making it firmer and stronger, or rather because at the *Iris* or *Rainebow* it is ioyned to the rest of the Membranes.

The vse of the *Adnata*.

In like manner it tieth the eye to the eye-lids & to the head, & in a word it defendeth the eye from the hardnesse of the bones, it ioyneth it with the bones, the lids, and the rest of the coats, whereby it is so established that in violent motions it doth not fall out of his orbe, but is freely mooued; and besides it couereth the Muscles which mooue the eye and keepeth them in their proper seats, but because it hath rather the vse of a Ligament then of a membrane, we thinke it approacheth nearer to the nature of a Ligament.

The vessels of this coate.

This coate or Membrane or Ligament whether you list to call it, is sprinkled with many smal Veines [tab. 1. fig. 6, 7, 8, V] and Arteries, which commonly when the eye is in perfect health do not appeare. Sometimes they grow very red and being full of blood they strut therewith and so become more conspicuous as in the inflammation of the eye. For as *Hippocrates* hath it, sometime this white groweth red or blackish, or is full of blacke Veines; this Membrane or coate it is which communicateth to the eye the sense of Touching, because neyther without nor within it hath any sense at all, and therefore the pain which proceedeth from the eye-lids molesteth the eye only by reason of this Membrane.

The 2. Coate *Innominata*.

The second Coate of the Eye is called *Innominata* by some, as if it had beene but newly found out, whereas *Galen* knew it well enough, and in the second Chapter of his 10. Booke *de vsu partium* reckons it for the sixt Membrane. It ariseth from the Neruous Tendons or Chords of the Muscles and determineth neere the *Iris* vnder the *Adnata* or *Coniunctiue* Membrane: and these Tendons do encrease the whitenesse of the eye, because they haue a bright *Candor* or whitenesse. But being nothing else then the Chords of

of the muscles, it cannot be properly called a membrane but a part of the muscles, which together with them must needs be demonstrated, notwithstanding if any man list to stand vpon it and call it a membrane we will not gainsay him.

The vse of it.

The vse of it is, that by the interposition thereof the muscles might be more fitly inserted into the horny membrane [tab. 2. fig. 5. sheweth the same.]

The 3. coate,
Cornea.

The third coate of the eye is called *Cornea*, which is the first according to *Hippocrates*, and may well be called the thicke and hard coate both in respect of his substance and of his originall, because it is produced from the hard *Meninx* or the *Dura mater* which inuesteth the opticke nerue. And here we may take knowledge of the admirable wisdom of our Creator, who (as *Galen* hath excellently obserued in the 2. Chapter of his 10. Book *de vsu partium*) whereas in no other place he hath separated the *Meninges* from any Nerue which are produced with them, but hath led them along with the nerue that they might be nourished and covered: onely in this place after the nerue is inserted into the cie, hath separated both the thicke and the thin from the nerue it selfe; yea made them thicker and harder then they were when they encompassed the braine. For when this membrane is implanted into the backpart of the eye [tab. 3. fig. 3. c.] it is dilated and maketh an orbicular or round membrane [tab. 3. fig. 2. and 3. exhibite it] which compasseth the whole eye, although it be not in euery place alike, neyther haue one and the same name; for the forepart is translucent but the backpart is not so; wherefore some immitating the Arabians of this membrane haue made two. For because the sight did stand in need of transparencie, this membrane, when it hath attayned vnto the middle of the forepart of the eye iust against the *Chrystalline* humor, it is so condensed that it degenerateth into a horny substance, which forepart [tab. 3. fig. 1. c. m.] is called *κερατοειδης Cornicularis*, that is Horny, because in the middle as farre as the extent of the Rainbow it is like a thin and polished horne of a Lanthorne, not only in transparency by which meanes it receiueth the light, but also in his substance, because it may be sliuen or deuided into diuers flawes. And that was the reason why *Fallopins* in his obseruations could not perswade himselfe that it was a part of the hard membrane because, saith he, it differeth from the *Dura meninx* of the braine, not onely in substance but also in thicknes and in figure. For by it selfe alone it maketh another sphericall cavity arising beyond the superficies of the hard membrane, and both within and without is free from any connexion.

How it is
spred ouer the
eye.

Why it is
compared to a
horne of a
Lanthorne.
Fallopins his
opinion.

The forme
and dispositi-
on thereof.
Why round
and circular.

This horny membrane is round, circular, hard, fast, thin, streatched, transparant, bright, polished and smooth. Round and circular in a man (for in Oxen it is of an ouall figure) bunching or bearing out in the middle of the eye not onely that it might bee freer from being offended: but especially that the eye might discern things greater then it selfe; that is, that it might receive the *Ideas* or formes of great obiects and those whole and vnbroken, as also that the light which entreth in might be better vnited and contracted, and so attaine through the *Pupilla* or Apple vnto the *Chrystalline* humour. That this benefit commeth by the roundnesse and prominence of this membrane may bee demonstrated by a Looking glasse, for if we desire to see our faces in a long fragment of a Looking glasse we cannot see them whole, because the figure is playne, and in a plain figure the perpendicular beames of the light are not vnited: whereas in a round figure they concur and meete together into a poynt: for *Galen* saith in the twelfth Chapter of his 10. Booke *de vsu partium*, that *Vision* or *Sight* is made by a *Pyramis*, and therefore let the glasse be neuer so smal, yet if it be round wee may see our whole face therein: hence it appeareth that if this part had any figure sauing a circular, the images or formes of great obiects could not be admitted into the cie at all.

Why hard.

It is hard and in some *Fishes* sayeth *Aquapendens* exactly carrieth the hardnesse and rigidity of a horne it selfe. This hardnesse secureth not onely the membrane but also the *Chrystalline* humour from outward iniuries: beside that, it resisteth any light occurrent violence.

Why fast.

Fast and thight it is, not onely for resistance, but also for the better conseruation of the watery and glassie humors that they sweat not out, and that the subtil spirits might not penetrate through it and so exhale. Wherefore in a liuing creature because of the abundance of spirits, it is notably streatched and shineth very cleare especially in the forepart. But when the creature is dead and the spirits extinguished, it falleth presently and growes loose and corrugated.

Hence it followeth that sight cannot bee by an emission or eiaculation of spirits out of the

the eyes, because

Hence it is tha
will bould his ha

the eyes, because the tention or stretching of a living eye proceedeth from no other cause but from the abundance of spirits concluded and contained within this membrane. And although it be the first and next part of the eye which is exposed to all injuries of cold, heat and whatsoever else might fall upon or bruise the eye, yet by the wisdom of Nature it is defended by the lids, by the hairs, by the bones and by the skinne. Moreover it is not a simple or single membrane but made as it were of many shels or scales, upon which sayth *Ruffus* in the fifth Chapter of his first Booke, there is a cuticle or curtaine spread which is far thinner then the rest of the scales, that if haply one of them should bee gnawne asunder, the rest might suffice to containe and defend the ChrySTALLINE humour. *Auicenna* maketh it foure-fold.

It is very thin, for sayth *Galen* in the third Chap. of his 10. Booke *de usu partium*, if it had beene thicke it might indeede haue beene a defence vnto the eye, but it would haue cast a perpetuall darke shadow vpon it, and would haue hindered the passage of the light; whereas now being thin it transmitteth any light or brightnes freely and without delay: so that the ChrySTALLINE humour may discern the true portraictures and representations of all visible objects; wherefore also it is transparant, cleare and bright because it should be more fit for the transmission of illumination, for so we see that the thinner a horne is the better doth the light extend it selfe through it.

It is also stretched, for if it had beene corrugated or wrinkled and so vnequall, it must needs haue lost his roundnesse, smoothnesse and transparancie; and so the sight would haue beene much hindered. An experience whereof we haue in old men in whome this membrane is sometimes so rugous and loose, that eyther they can see nothing at all or very confusedly, for, saith *Aquapendens*, when one plight or fold falleth vpon another and the coate thereupon is duplicated, the membrane becomes thicker and the Apple contracteth it selfe because it is not distended by sufficient affluence of spirits.

It is transparant that it might giue way to all visible formes and representations, and also admit the light which beateth vpon it. But we must consider that this transparancie or lucidity of the membrane differeth much from the lucidity of the aire, that so there might insue a refraction or breaking of the light. But how the light passeth vnto the eye and how it is refracted, because it belongeth rather to the opticke Art then to Anatomy; him that listeth to be further satisfied therein, we will send vnto the writers of the Opticks, such as are *Vitellius* and *Albaren*. *Aquapendens* also the Anatomist hath elegantly written of these things of the eye: but we proceed.

This membrane is polished and smooth that in it the formes of things might better shine and more fitly be receiued, and images represented to the ChrySTALLINE humour most like to the outward objects. For if it had beene rough and full of eminencies and cauities, the light would not haue equally attained vnto it; for where cauities are there doe the representations passe through more easily and brighter; where there is any eminency there doe they passe through with more difficulty, and beside are very obscure. Moreover such an asperity or roughnesse would haue beene troublesome to the eye-lid, as wee see it happeneth when any small substance falleth betwixt the eye and the lid. But being fast, hard and thin, it could not receiue any veines into it, neyther yet arteries nor nerues: neyther if it could had it beene behoofeful, for they would haue hindred the sight, & although it might haue defended the ChrySTALLINE humor from outward offences, yet it would haue beene offensive to the sight with his hardnesse: and finally it would haue abated the visible faculty communicated vnto the eyes from aboue, and haue dimmed or dulled their brightnes. For that the eyes are offended with a bright and vehement light, euery man hath sufficient experience in himselfe. Beside, we reade in Histories that *Zenophons* souldiours were almost blinded by traouelling through the snow. And *Dionisius* that Tyrant of *Sicilia* aboue his prison built a very lightsome and bright chamber which he whitened ouer with lime, & when he had a long time detained his prisoners in a darke dungeon, he suddenly brought them into this light and bright place, where they instantly became blinde because their eyes were not able to beare so sudden a change.

In like manner those that doe labour of the *ophthalmia* or inflammation of the eye are offended with the light: but duskish or greene colours they are able to behold without offence.

Hence it is that if in a bright light a man would looke on any thing that is a far off, hee will hold his hands or some other thing ouer his browes to shadow his eyes that they

The greater light extinguisheth the lesse.

be not dazled. So also it hath bene obserued, that those that haue fixed their eyes vpon the Sunne to behold the Eclipses of the same, haue vtterly lost their sight. And this cometh to passe, even as we see a torch or candle lighted and set in a bright Sun is instantly extinguished: In like manner if you light a candle and set it by a great flame, the candle will presently go out, because the lesse light is overcome and dissipated by the greater.

tor acknow-
ledged by
Galen.

After the same manner in the eye, not onely the splendor of the Christalline humour, but with it also the brightnesse of the glassie humour is dissipated: wherefore the wise and prouident Creator, saith *Galen* in the third Chapter of his tenth Booke *de vsu partium*, hath interposed the coat called *Choroides*, which in many parts is blacke and dusky, and in oxen Greene; which coate nourisheth the horny coate that is next vnto it where they touch one another, and hindereth it also from falling vpon the Christalline humour, although that inconuenience is in part preuented by the roundnesse and prominence of the saide horny coate.

Moreouer, the blacke colour of the *Choroides* in men, and the Greene colour in Oxen, is a medicinable curtaine or shadow for the ill affected eye; and this is the reason that euery man by a naturall instinct, when he is offended with the brightnesse of the light, will suddenly close his eye-lids, making haste thereby vnto the remedy which Nature hath prepared, euen within the eye. And this may be further exemplified by the custome of Painters, who when they paint vpon white tables would soone haue their eyes offended if they did not prepare against it, wherefore they place at their elbowes Greene and dusky colours, vpon which euer and anon they turne their sight, whereby their eyes are recreated and refreshed.

The back-
part of the
horny coate.

The posterior or backward part of this coat which couereth the back-part of the eye and the forepart also vnto the circle, [tab. 1. fig. 7, 8. f] is hard, thicke, darke, or obscure; differing as much from the colour or clearenesse of the horny membrane, as the white of an Egge when it is boyled differeth from the same white when it is raw. It is hard and thick by reason of his originall, although it neither imitate the exterior coate of the nerue in thinnesse, nor the *dura meninx* or thicke membrane of the braine from which that ariseth in thicknesse; as being fourefold thicker then it, for when it formeth the coate of the eye it is thickened and hardened, for it was requisite it should be very hard and very thicke for more strength, because it maketh the whole globe and cavity of the eye wherein the humors are contained: for this membrane it is which fashioneth the figure of the eye into a globous roundnesse, and in that figure conserueth it: it is also made whole, for this coate about compasseth the whole eye so that nothing can issue therout.

Why it is so
thicke.

Add hereto that it receiue the insertions of all the muscles and sustaineth their weight, as also the weight of the fat, and is a Basis or foundation of the veines and arteries [Tab. 3. fig. 3. h b] which neare the nerue behind the glassy humor attaine vnto this membrane and afterward run forward till they be distributed through the coate called *Choroides*. By the mediation of these vessels, as also by smal-ties, as it were by ligaments this membrane cleaueth so fast to the *Choroides*, that they hang one vpon another. [tab. 3. fig. 3. h i] The profit of which connexion is, lest this coate alone should be mooued when the other parts of the eye are at rest, as wee see a cloth wrapped about a smooth bowle will easily slippe, though the bowle be not moued.

Why it is
thicke and
darke.

Fuchsius
Aquapendens.

This membrane is also thicke and darke or obscure, that the *species* or formes of things which are received might shine more brightly, as we see in a looking glasse if it be leaded on the back side we may easily see our faces therein, but not so if the lead be removed. This part is white, and neither in nature nor in colour like vnto the forepart, and therefore some of the late writers as *Fuchsius* & *Aquapendens* haue distinguished it from the forepart, and say, that the limits and edges thereof are continuated with the horny membrane. It is situated vnder the Coniunctiue and Tendons of the muscles, and is generated out of the *dura meninx* which compasseth the Optick nerue, for with it it is continuall, as may be perceived if you separate the coate of the nerue with a sharp knife through his length whilest you come vnto this membrane. It is called by some *σκληρότης* & *σκληροτική* the hard membrane, *Ruffus* calleth it *candida* or the white membrane, although commonly that name be giuen to the *Adnata* or Coniunctiue coate.

Ruffus.
The vie of
this third
membrane.

By the helpe of this membrane is the eye established, as also the next membrane vnto it defended, which is sufficient indeed to defend that which is vnder it, but not to defend it selfe: this also is it which containeth the humors according to their due disposition;

sition; and whereby the Christalline humour it selfe is preferued from the cold and heate of the Ambient ayre.

CHAP. VII.

Of the Grapy Membrane, the Apple, Rainebow and the Ciliar Ligament.

THe fourth coate or Membrane of the eye is called by the Greekes *παρυσίς* and *παῖξ*, in Latin *Fua* or the Grapy Membrane, because the colour of it is like the peeke of a Grape stone or kernell, or it is like the kernell it selfe which is on the outside smooth, but within sharpe and rough; in like manner this Membrane on the out side which is next the horny Membrane is smooth but on the inside which is next the Christalline it is rough or rather vnequall because of the furdles of veins and arteries which reach out of the horny Membrane into it. [tab. 3. fig. 3. and 4. l.] Againe it resembleth the Grape kernell in the colour which is blacke, or rather because it containeth a whitish humour such as yssueth from the grape when the stalke is pulled off.

The 4. coate
of the eye.

The reason of
the name.
His situation

This Membrane is scituated betwixt the *Cornea* and *Retina* vpon which it lieth onely on the backside, but foreward it is betwixt the *Cornea* and *Aranca* and containeth the watery humour of the eye. [table 3. figure 1. c.] It is tyed backward to the Opticke nerue, and the coate called *Retina*: to the horny membrane it adhereth by certaine furdles of veines and arteries [tab. 3. fig. 3.] and to the rainbow by Fibrous ties which are not very strong. Before it is euery way free and loose, that it might be contracted and dilated.

The figure of it is not exactly Globous as the former, because it doth not compasse the whole eye, but in the forepart [tab. 3. fig. 4. m. n. fig. 7. at n.] it is a little pressed inward, where also it is perforated with a round hole.

His figure.

The originall of this coate *Galen* saith in the second Chapter of his 10. Booke *de usu partium* is from the *Pia mater*; [tab. 3. fig. 1. f. fig. 4. and 5.] for when the *Pia mater* or thin Membrane hath inuested the Opticke nerue, [tab. 3. fig. 2. b.] it is presently dilated vnder the *Cornea* to make this Membrane: wherefore it creepeth forward and compasseth the whole eye, excepting the forepart where at the greater circle or rainebow of the eye, it is continued with the *Cornea*, and being reflected backward is duplicated and in the middle perforated, which perforation is called *Foramen vnea*, the hole of the grapy membrane and by a proper name *Pupilla* which we may interpret the Apple of the eye. Notwithstanding it is farre thicker then the *Pia mater*, especially in the forepart where it is double as thicke as it is behind. Againe, it differeth from the *Pia mater* in colour, for the coat of the Nerue which it receiueth from the *Pia mater* is white, but this is blacke on both sides.

His originall.

Moreover, because it proceedeth from the *Pia mater* or thin membrane, it is called also *χοροειδής* especially, because through it there are many vessels disseminated, and because like the Chorion of the wombe it gathereth those many vessels and tieth them together; and this in oxen is easie to be discerned, for in them the vessels do run through the length of the eye in a conuenient distance one from another, from which vessels certaine threddy filaments or small strings do as it were weaue together this membrane like as it is in the *Pia mater* of the braine. From this membrane also the fore said strings and threddy vessels are produced into that coate which we call *Retina* as may easily be perceiued when this Grapy membrane is separated therefrom.

Why it is called
Choroides.

This Grapy coate therefore is full of veines, soft, blacke, and perforated.

His vessels.
Why it is soft.

Full of Veines, that it might nourish the horny membrane: soft that it might not hurt the Christalline humor, and beside might readily moue when the *Pupilla* or Apple moueth, which it would not so readily haue done if it had beene rigid or stiffe.

It is blacke or rather duskish, the better to gather the brightnes of the *Idea* together, and to transmit it through the perforation.

Why blacke.

Finally, it is perforated iust against the Christalline humor, that so the Images of visible things passing through the horny membrane and waterish humour might at length arriue at the Christalline. And although it be moist and soft and neare neighbour to the Christalline, yet is it not offensive thereto; albeit on the outside it be something thicke or rather fast wrought: for as it was fit that this membrane should not offend the christalline humor, so likewise was it as fit that it selfe should not be offended by the horny membrane; betwixt

Why perforated.

the

the transparant part whereof and the chrySTALLINE humour it is seated, and yet it toucheth neither of them.

Furthermore, that the chrySTALLINE humour might not bee offended or touched by the horny coate insinuating it selfe through this hole or perforation, by which the externall brightnes attayneth vnto, and is mingled with the internall; Nature hath set that part of the horny membrane outward, and beside hath disposed about the ChrySTALLINE a thin and cleare humor like the white of an egge; and lastly hath filled the whole perforation with an ayery and bright spirit. And that this place hath such a thin moysture and is full of spirits is hence manifest, because in liuing creatures the eye is stretcht and fulfilled on euery side, no part of the horny membrane remayning loose or corrugated.

What is contained betwixt the grapy membrane and the chrySTALLINE humor

But if you looke into the eye of a dead man before you come to dissect it, you shal find it rugous, and when you haue cut the horny membrane presently a thin humor will offer it selfe (which also in compunctions of the eye doth vsually yssue from the wound) and so the whole eye will become rugous, contracted and loose. Againe, if you distend and stretch the coates when they are separated from the ChrySTALLINE humour, it wil appeare that there is a great distance betwixt them empty, which while the creature was aliue was vndoubtedly filled vp with spirits or humor or both.

The spirits of the eye.

The like also may be demonstrated in a liuing eye, for if one eye bee shut the *Pupilla* or Apple of the other will be dilated, enlarged and distended as a bladder that is blowne vp; what then should distend or enlarge this *Pupilla* or perforation, sayth *Galen*, but only a spirit? And this indeed is his argument whereby he proueth that there is an Animall spirit. For, faith he, this amplification or enlargement hapneth because all the spirits doe assemble themselues vnto the eye which is open, whereas when they are both open the spirits are equally diuided betwixt them. *Galen* also proueth the same thing by dissection; for if you blow vp the grapy membrane on the backside you shall perceiue that the *Pupilla* or perforation will be enlarged. Wherefore it followeth necessarily that all that space which is before the chrySTALLINE humor is filled with spirits and a thinnie humor. The thinnie humor sheddeth it selfe in all the other parts but in the very *Pupilla* or perforation the spirits are gathered together.

The *Pupilla* or Apple of the eye.

This *Pupilla*, is called *νοπή* by *Hippocrates* in his Booke de *Carnibus*; by *Galen* in the fourth Chapter of his 10. Booke de *usu partium* 64. [tab. 3. fig. 4, 5, 6, 7. n] In Latine *Pupilla*, *oculi fenestra*, the window of the eye, *nigrum oculi* & *foramen oculi*, wee vse to call it in our language the Apple of the eye.

It is a hole or perforation of the grapy membrane and is otherwise called the lesse circle of the eye (as the greater circle is called the Rainebow) [Table 3. fig. 2, 3. g] because it appeareth in the center of the eye like a blacke point. Blacke (I say) as well because of the deepe scituation, as also because the coates which compasse it about are of a darke colour. This hole or perforation is not onely lesse then the compasse of the horne, but also there is some distance betwixt them, least otherwise the ingresse of visible images through the horne might be interrupted; wherefore when the grapy membrane commeth to the translucent part of the horny membrane, it is no more round but reflected backward and inclineth toward the chrySTALLINE humour, leauing a hole in the midst which is called *Pupilla*, as *Varolius* hath elegantly deliuered.

The fig. of it.

This *Pupilla* or Apple of the eye is in man and some other creatures as Dogges very round: in many brute beasts, as Oxen, Sheepe and Goates it is longer then round, of an Ouall fig. or like a circle compressed in the midst, which compression is dilated or contracted according to the motion, eyther proceeding from the Animall spirit, or from the light: so that the figure thereof is sometimes round, sometimes long, sometimes wide sometimes very narrow, as in a Cat whose *Pupilla* is like a narrow and long cleft; *Aquapendens* faith, that in a Pike it is of the figure of a cone.

How the *Pupilla* is contracted and dilated. *Galen*; *Aquapendens*.

The dilatation and contraction of this *Pupilla* or Apple of the eye, *Galen* ascribeth to the Animall spirits, but *Aquapendens* thinkes that the hole of the *vnea* or grapy membrane, (which is all one with the *Pupilla*) is dilated or constringed according to the strength or weaknes of the light that beateth vpon it. For in a stronger light it is contracted the better to defend the chrySTALLINE humour, which is oftentimes offended by a strong light. In a lesfer or weaker light it is dilated to helpe the sight to discerne of many visible things, which otherwise would not appeare; (And therefore those that complaine of the weaknes of the eyes and sight must haue them viewed rather in an obscure and darke, then in a Lucide or bright

bright place) and so it cometh to passe that a strong light doth not offend the eyes, because it is admitted to the cristalline humour in a lesse quantity; nor a weake proue insufficient because it is received in greater quantity.

That the motion of the *Pupilla* is not from the Animall spirit as from the efficient cause hee proueth, because a strong light attenuateth the spirits, diffuseth them, and so should consequently enlarge the *Pupilla*. On the contrary, a weake light doth dull and diminish the spirits and so the *Pupilla* should be straitened, whereas common experience teacheth vs the quite contrary: wherefore saith *Aquapendens*. I conceiue that the dilatation and contraction of the Apple of the eye proceedeth from a proper faculty of the Grapy coate, which Faculty notwithstanding is stirred vp by the externall light which entred into the eye, and yet we see that in Suffusions and Catarracts the *pupilla* is dilated and constringed when a strong light cannot offend such eyes because it hath no free passage, the Catarract or cloud being interposed betwixt the light and the sight: howbeit even in such Suffusions if one eye be shut the *pupilla* of the other is dilated, which can bee from no other cause but onely from the spirits.

The vse of this perforation or *pupilla* is to transmit the visible images to the Christalline humour: for (saith *Galen* in the fourth Chapter of his 10. Booke *de usu partium*,) vnlesse the Grapy coate had heere beene perforated al the parts of the eye had bin created in vaine, because the Christalline humor hath no communion with his obiects but onely by this perforation of the grapy Membrane, and therefore according as this apple of the eye is dilated or contracted, so do we see better or worse. And hence it was that *Galen* in the second chap. of his first Booke *de symptomatum Causis* hath well obserued that the dilatation of this Apple of the eye, whether it be an originall fault in Nature or happen after by accident, is alwayes a great weakner of the sight. On the contrary, the coarctation or straightning of the *pupilla* if it be naturall is the cause of the quickenesse and vigour of this sense, for when it is notably dilated the animall spirit which floweth into the eye cannot fill the whole space which is before the Christalline humor; whereas on the contrary when the *pupilla* is contracted or gathered together the space is sooner fulfilled.

Add heereto that for the perfection of sight it is very necessary that the visible species or Formes should flow vnto the eye by a right line and so passe vnto the Center of the Chrystalline with a pointed angle; for so they make the better impression, and therefore the perforation or the *pupilla* is very narrow that the lines produced from the Circumference thereof as from a basis might touch the center of the Cristalline in an acute angle; for if the *pupilla* be so dilated that the lines produced from the circumference thereof do make a right or obtuse angle in the center of the Christalline, then is the sight not onely offended but abolished.

Hence it appeareth that the naturall latitude or straightnesse of the *pupilla* maketh much for the strength or weaknes of the sight, especially if the distance betwixt the visible obiect and the organe of the sense be proportionable. But to returne vnto the grapy Membrane, of which this apple of the eye is but a perforation.

This Membrane according to the difference of the parts thereof hath diuerse colours, for on the outside where it toucheth the horny Coate it is blacke; on the inside where it respecteth the watery and Christalline humours it is blacke or dusky. But where it maketh the greater circle which we call the Rain-bow (according to the diuers temper of the Braine and the eyes saith *Laurentius*) it is sometimes greenish, sometimes skie coloured, sometimes blacke. Finally, the backward part of this Membrane where it first ariseth from the *Pia mater* is whitish, presently it groweth greenish, then nearer vnto a blew, all which colours may be best discerned in the eye of an Oxe. This blacke colour (as *Galen* sayth in the third Chapter of his tenth Booke *de usu partium*, where hee speaketh of a skie colour because he described the eye of an Oxe) is very worthy of admiration, because there is no such colour found else-where in the whole body. And although in some eyes it is lesse or more blacke then in others, yet in all it is eyther blacke or browne, that the Christalline humour being therewith couered might better collect and gather his brightnesse together. For as a small light in an obscure and darke place is better perceived and shines brighter then in an open and light place, and maketh those things which are about it better to be perceived; so the brightnes that is enclosed within the eye becomes more bright, and the visible species do better appear in the cristalline humour, because the

the eye hath
by his blacke
colour.

How the colour of the inside differeth from the colour of the outside.

the inner circumference of the whole eye is inuested with this obscure and darke Membrane, by whose shadow the chirstalline is compassed; so that his brightnesse returning backe from the blacknesse and obscurity of the membrane is vnited better into himselfe. And so (as *Aquapendens* hath well obserued) that light which is but weake, or but moderately strong doth better appeare in the Chirstalline then that which is much stronger, as whereby the inbred light of the humour it selfe is ouercome.

Againe, we say that the darknesse of the colour of this membrane maketh much to the collection and refraction of the spirits. For when the Chirstalline is too much affected by a vehement light, then we close our eyes, and the spirits turning themselues vpon those darke colours are refreshed, as before hath bene shewed in our History of the horny membrane. Wherefore also about the *pupilla* it is thicker, because it should cast a greater shadow vpon the Chirstalline in that place where the light hath his accessse, for on the backside it is compassed with the thicke and fast horny coate. And for this cause betwixt the horny membrane and the Chirstalline humour this coate is blacke. But this blacknesse on the inside of the coate where it respecteth the humors, seemeth to be bred with the coate it selfe, but on the outside where it respecteth the horny membrane, I conceiue it is but accidentary because it will colour a mans finger that toucheth it, and may easily be washed off so that the membrane will remaine white; but the colour on the inside will not die or taint the finger, for if it were so those bright bodies which it respecteth and compasseth would be soyled by that blacknesse, and so loose their purity. Some are of opinion that this blacknesse is the thicke excrement which is separated in the nourishment of the Chirstalline humor, as also that the watery humor is the thin excrement of the same.

A mans eye is of diuers colours.

Now as this blacknesse is perpetuall in all creatures on the outside of this coate, so on the inside, especially where it respect the glasse humour, the membrane is sometime browne, sometime purple or skie coloured (whence it was that *Galen* in the fourth Chapter of his 10. Booke *de usu partium*, called it a skie coloured coate) and sometimes green as in oxen; but where it is perforated on the foreside and respecteth the shining or transparent part of the horny Membrane it is not in man of one and the same colour; yet so that it is alwayes of that colour which we see in the Rainbow of the eye, according whereto we say a man hath blacke or browne, or skie coloured, or a Goates eye, which saith the Philosopher is an argument of a good disposition: so that the same *Aristotle* in the fifth Booke *De generatione Animalium* and the first Chap. hath well obserued that among all creatures onely man hath eyes of diuers colours, for other creatures among all of the same kind haue eyes alike, excepting horses, who sometimes haue wayle eyes.

The Rainbow of the eye.

The Raine bow called in Greeke and Latine *Iris*, hath his name from the similitude of the Raine bow which appeareth in the clouds, because this greater circle of the eye [tab. 1. fig. 7, 8, f. tab. 3. fig. 2, 3. f.] is distinguished with diuers colours which shine through the horny Membrane. *Galen* in the second Chapter of his 10. Booke *de usu partium*, saith, that in this Raine bow there are seuen circles one within another, all differing in thickenesse and colour, which proceed from the Membranes. But how nice a peece of businesse were it in dissection to offer to shew all these circles distinctly without confusion? surely so hard a matter it were to accomplish as vaine when it were performed, Some haue called this *Iris* *secundum a Crowne*.

Diuers opinions of the cause of the Rainbow.

There are many opinions of the causes of so great variety of colours in this circle of the eye, and if you wil giue me leaue I wil acquaint you with what other men haue conceiued, and then deliuer that opinion which I follow my selfe.

Empedocles.

First of all therefore *Aristotle* in the first Chapter of his fifth Booke *de generatione animalium* maketh mention of *Empedocles* his conceit, who compoundeth the eye of fire and water. The skie coloured eye saith he, is when the fire beareth the sway, and the blacke eye when the water exceedeth the fire.

Aristotle.

Aristotle in the place before quoted refers the variety of the colours to the plenty or scarfity of humors, and maketh demonstration of his opinion by the example of ayre and water: for, saith he, if you looke vpon a deepe water, or a thick ayre they will seeme black and obscure. But if there be but a little of either, then wil their colour appeare blewish and bright. This conceit of *Aristotles*, *Columbus* reprehendeth, but gratis; for he addeth no reason against him.

Galen:

Thirdly, *Galen* in *Arte medicinali* is of opinion that the plenty of splendor & scituation of the Chyrtalline & watery humors is the cause of this variety of colours. The eye, saith he, be-

becommeth skye-coloured, either because of the plenty or splendor of the Chrystalline humor or by reason of his prominent scituation, whereto he addeth the paucity and purity of the watery humor. The eye is blacke when the Chrystalline is little or scituated somewhat too deepe, or because it is not exquisitely bright, or because the watery humor is somewhat more plentifull and yet not pure. *Vesalius* reprehendeth *Aristotle* and *Galen* in these words, which indeed are but bare words. This color, saith he, ariseth not from the plenty, defect or tenuity of the humors of the eye, neyther yet from the collection or dilatation of the Apple, and finally not from the depth of the eye or the tenuity thereof.

Fourthly *Auicenna* referres the cause vnto the color of the grapy coate, which as it is diuersly depainted so it bringeth forth in the eye diuers colours: if it be sky-colored the eye is also sky-coloured, if blacke, the eye is blacke. And him doth *Vesalius* follow.

Fiftly, *Auerrhoes* imagines that the whitenesse of the eye proceeded from cold, and the blacknes from heate.

The sixt opinion is that of *Varolius*, who saith, that the cause of the colour is to be referred to the vnequall plenty of the spirit and of the watery humor, which as it falleth in diuers parts of that place so it representeth diuers colors. The color saith he which resulteth from the grapy membrane receding or giuing backe from the horny, is wont to bee called the Rayne-bow from a certaine appearing variety: he calleth it an appearing variety, because in very truth there is not in that place any true diuersity of colours but onely in apparition, because the horny membrane standeth vnequally about the grapy, and so an vnequall quantity of spirits and humor fall betwen them.

The seuenth opinion is that of *Archangelus*, who writeth that the diuers colours in the Raine-bow are caused by the inequality of the veines which are in the grapy coate (which veines are also comunicated to the coate called *Aranæa* or the cob-web) containing in them blood diuersly prepared according to the variety of the parts that are to be nourished, which are much vnlike other parts of the body. He imagineth also that the grapy membrane is not of one colour in men, that their eyes being wearied might be recreated, especially by green, of which there is most in the world; and hence it is that we do often shutte our eyes, that so the spirits that are spent or wearied may be restored and refreshed.

The eight opinion is that of *Laurentius*, who referred the cause to the watery and chrystalline humors, to the variegation or diuers colours of the grapy coate and to the spirits, which opinion also we will follow as seeming most reasonable. For the cause of the sky-coloured eye in respect of the chrystalline humor is the plenty thereof, the splendor & the prominent scituation; in respect of the watery humor the splendor and the paucity, for when the watery humor is but little it doth lesse hinder the fulgent brightnes of the chrystalline.

The blacke eye hath quite contrary causes, to wit the paucity of the Chrystalline humor his impurity and deepe scituation, as also the impurity and plenty of the watery humor.

The colors betwixt these depend vpon intermediate causes.

In respect of the Grapy Membrane, the colours of the eye do differ, as when it is simply variegated or diuersly streyked then is the eye also of diuers colours, because in that place the Grapy membrane is diuersly discolored.

In respect of the spirits the colours of the Raine-bow differ, for thinne, pure, bright and plentifull spirits make it sky-coloured, on the contrary, crasse, impure, cloudy and few spirits may be the cause of this blacknesse.

The vse of this variety of colour in the Raine-bow some referre vnto beauty, or happily by reason of this diuersity of colours the diuers colours of externall things are there better expressed and offered to the chrystalline humors. But in those creatures which see in the night, the Iris is onely a bright place which if it happen in a man, as *Suetonius* reporteth of *Tiberius Caesar*, he also will see in the night.

Finally this grapy membrane some of the new writers, as *Enschinus* and *Aquapendens* imitating the Arabians haue deuided into two parts, the forepart they call *uena*, and the back-part *Choroidea*, and thence is the difference of his names.

From the circumference of the grapy coate [tab. 3. fig. 17.] doe directly proceed certaine small filaments or strings like blacke lines, which resemble the haire of the eye-lids. These strings reach vnto the margent or brimme of the Chrystalline humor, and although they be placed in the cob-web coate yet they compasse the Chrystalline humor round about. By the mediation of these hairy threds the grapy Membrane is ioyned to the circumference of the Membrane which immediatly inuesteth the Chrystalline humor [tab. 3. fig. 7. 0 0] and so

the cristalline humor it selfe is tyed to the neighbour parts: wherefore because it doth the office not of a Membrane but of a Ligament or Tie, *Fallopins* from the forme calleth it *Ligamentum Ciliare* or the hairy Ligament, others call it *Interstitium Ciliare*, because it disseuereth the watery humour from the glassy.

CHAP. VIII.

Of the Cobweb or Membrane of the Christaline humor. Of the Membrane which compasseth the glassy humor, and that coat called Retina, or The Net.

The Cobweb
or coat of the
christaline hu-
mor.
Divers opini-
ons of his Ori-
ginall.

He Membrane which immediately compasseth the Christaline humor is called in Greeke *ἀραχνειδής*, *Aranei-formis*, that is the Cobweb, most properly is it called *Κρυσταλλοειδής* from the humor whose proper coate it is, yea the very superficies of the same. Some call it the Looking-glasse, because it is bright and transluceid. Some thinke it hath his originall from the *Pia Mater*, and of that opinion is *Columbus*. Others from the coate called *Retina* of the net as *Aquapendens*, but *Archangelus* conceiueth that it is made of the Opticke Nerue dilated and drawne out into a wonderfull thinnesse. But we are of opinion saith *Banhsine*, that it is engendred in the first conformation, together with the cristalline humor which is framed of the purest and brightest portion of the seede. It is a Membrane most thinne (so saith *Hippocrates* in his Booke *de Locis in homine*) very fast, most light, white, bright and shining beyond measure, the better to admit the light and to be changed thereby, (for onely this Membrane dooth indeed receiue and apprehend the affections of the light) and least if it had beene thicke it should haue hindered the sight.

The substance
of it.

The substance of it is much like the inward skinn of an Onion or rather like a spiders Cobweb, for the finenesse I meane, and not for the density or fastnesse thereof. This Membrane couereth the cristalline humor both on the foreside and the backside immediately compassing and establiishing the same. Although I know that *Galen* in the 6. Chap. of his 10. Booke *de usu partium* writeth, that it inuesteth this humor onely there where it toucheth the grapy Membrane, with whome *Archangelus* also agreeth. But that the whole cristalline humor might be more fit for sensation, it was necessary that it should be compassed round with this Membrane, which notwithstanding wee acknowledge to bee thicker, faster and stronger on the fore-side. For because we see before vs, therefore the faculty and power of this sense ought there to be more vigorous, because in that place the light is more strongly vnited by the roundnesse of the cristalline and the refraction of the watery humors. And therefore *Ruffus* calleth it *Visio & Pupilla*, the sight or Apple of the eye. And because in this as it were in a glasse the Effigies or Image of the *Pupilla* doth consist, therefore *Galen* in the place next before quated, calleth it the Idoll or Image of the sight. On the contrary the backpart of it is looser, thinner and more rare.

Why thicker
before.

The vse of it.

If this Membrane be taken away, the figure of the Christalline humor is destroyed; for whereas before it was smooth, equall and polished; now it falleth asunder and becommeth vnequall, not being able to stand together when the bande which conteyned it is remoued. In a word, the cristalline humor receiueth from this Membrane not onely his sensatiue power, nor the forme and figure of his substance, but also his efficacy and virtue. Veines it hath none, but seemeth to be nourished by the Ciliar Ligament.

The coate of
the glassy hu-
mor.

The coate of the glassy humour is called *δακρυειδής*, which *Columbus* and *Archangelus* haue confounded with the cobweb before described. But the trueth is, that their substance is different, for this is thinner then the former and encircleth the watery humor round about least it should either be diffuent or confounded with the watery humor. Other Anatomists haue altogether pretermitted the mention thereof, because they thinke that both humors are involved by the Cobweb Membrane. In the midst of this coate doth the Ciliar or hayry Ligament appeare.

The Net.

The last Membrane or coate of the eye is called *Retina* or *Reti-formis*, [Table 3. fig. 8.] in Greeke *ἀμυδανειδής*, because it resembleth a little round casting Net. This Membrane ariseth from a part of the Braine descending thorough the Opticke Nerue, or if you will, from the marrow of the Nerue it selfe as soone as the Nerue attaineth to the eye, and so hangeth at the very roote of the nerue, from thence it passeth on to the middle of the cie & within the cavity of the grapy membrane vpon which it immediatly lieth, but is not tyed there-

thereto. It is enlarged and like a net or caule compasseth the glassy humor, but without any connexion at all, *Aquapendens* saith, it is inserted into the vtmost circle of the Christalline humor, and that by the meanes hereof the Christalline swimmeth in the midst of the glassy humor as a peece of wood swimmeth in the water. It is soft, reddish, of a mucous substance, not solid and crasse as is the substance of the braine.

The substance thereof.

Wherefore, neither in substance nor in colour is it like a Membrane, and therefore *Galen* in the second Chapter of his tenth Book *de vsu partium* saith, it neither deserueth the name of a membrane nor of a cote, for if you separate it from both the humours and lay it vpon a heape by it selfe, [table 3. fig. 8. 1.] it will seeme to you to be a part of the braine dilated, and therefore *Galen* calleth it the net-like body; *Vesalius* saith it can haue no fitter name then the name of a coate, albeit *Columbus* and *Platerus* are not of his opinion. Veines and Arteries it hath very many and conspicuous; and indeed more (though they be small) then seeme conuenient for the proportion thereof: for all nerues being inuested with a portion of the *Pia mater* wherein veines and arteries doe run, this also receiueth a veine and an artery diuersly branched, whereby Nature hath provided and prepared aliment not only for the Nerue, but also for the humors of the eye. In these vessels therefore is blood contained, not thicke nor faeculent but thinne and fluide, whereby the glassy and Christalline humors might be nourished, which because they are pure bodies do also stand in neede of pure blood.

The vessels thereof.
The prouisor
dece of nature

It is also darke and corpulent not translucent, that it might not be affected or changed by the light.

The first and greatest vse of this Net-like coate is, saith *Galen* in the 2. Chap. of his 10. Booke *de vsu partium*, that when the Christalline is altered, it might apprehend the Sensation, or rather to leade along the faculty of sensation to the christalline humor, because as we saide euen now, it ariseth from the substance of the nerue.

The vse of it.

Another vse of it is, that the visue spirits might be diffused through the christalline humour and the whole eye; to perceiue the alterations of the Christalline and to transport the images of visible things to the braine as to a iudge.

Finally, whereas it intercedeth betweene the Grapy membrane and the glassy humor it keepeth the pure substance of the glassy humor from being defiled with the blackenesse of the Grapy membrane. And so much concerning the membranes or coates of the eye. Now we proceed vnto the humors.

CHAP. IX.

Of the humors of the Eye.

THe humors which are the most noble parts of the eye are contained within their coates, and are three; differing each from other in figure and consistence; yet all bright and perspicuous, distinct in their seates, filling the cauities of the eye, and helping the action of the sight. These three humors are called the Watery, the Christalline, and the Glassy, amongst which the Christalline excelleth in dignity and vse and therefore is called the soule, the center and an inner Spectacle of the eye.

The three humors of the eye.

The watery humor [tab. 3. fig. 10, and 16. y, and 19.] is called in respect of the other humor *tenuis* the thin humour, and by some *Aqueus*, because it is fluide like water and also transparent. And hence haply it was that *Aristotle* maintained against *Plato* that the eye was not fiery but watery. It is also called humor *Albugineus*, because the colour and substance thereof is much like the white of an egge. This is the vtmost of all the humours filling the whole place which is betwixt the foreside of the Christalline, the grapy membrane which is there duplicated, and the horny membrane; sauing that it is accompanied with an ayry and bright spirit.

The watery humor.

What place it hath in the eye.

It is disposed on each side the apple of the eye, stable and not moueable, because it hath in it a kinde of *Lentor* or sliminesse. It is but little (wherein *Vesalius* was deceived) filling scarce the tenth part of the circumference of the eye. In or vpon this humor are those Suffusions made which they commonly call Cataracts.

Where cataracts are.

The vse of it is very notable, as we shall heare afterward, which hath moued vs to doubt whether it be a part generated of the seede as the other humors of the eye are, or an excrement

Table 3. figure 1. sheweth the Membranes and humors of the eye by lines drawne after the manner of a true eye.

Figure 2. sheweth the horny coate with a portion of the Opticke Nerue.

Figure 3. sheweth the same diuided by a transuerse section.

Figure 4. sheweth the Vnea or Grapy coate with a portion of the Opticke Nerue.

Figure 5. The Grapy coate of a mans eye.

Figure 6. The Horny, Grapy, and the Choroides.

Figure 7. The interior superficies of the Grapie coate.

Figure 8. The Posterior part of the horny coate together with the saide Net coate separated from the Eye.

TABVLA III.

The explication of the first Figure by it selfe.

a, The Christalline humor.

b, The Glassy humor.

c, The watery humor.

d, The vtmost coate called *Adnata*.

e, The darke part of the horny Tunicle which is not transparent.

f, The Grapy coate called *Vnea*.

g, The Net-like coate called *Retiformis*.

h, The coate of the glassy humor cald *Hyaloides*.

i, The coate of the Christalline.

k, The hairy processes cald *Processus ciliares*.

l, The impression of the Grapy coate where it departeth from the thicke coate.

m, The horny coate, a part of the thicke coate.

n, The fat betwixt the Muscles.

o, The optick Nerue.

p, The *Dura meninx*.

q, The *Pia Mater* or thin *Meninx*.

r, r, The Muscles.

The explication of the other 19 figures together:

a 2, 4, 8, The Optick Nerue.

b 2, 4, The thin *Meninx* clothing the Nerue.

c 2, 3, The thicke *Meninx* clothing the Nerue.

d 8, The posterior part of the horny Coate.

e 8, The coate called *Retina* gathered together on an heape.

f 2, 3, The Rainebow of the eye.

g 2, 3, The lesser circle of the eye or the *pupilla*.

h 2, 3, Vessels disperfed through the *Dura Meninx*.

i 3, 6, The Grapy coate, but, in the 3. Fig. sheweth how the vessels doe ioyn the hard membrane with the Grapy coate.

k 6, the horny or hard membrane turned ouer.

l 3, 4, Certaine fibres and strings of vessels, whereby the grapy coate is tied to the horny.

m 4, 5, the impression of the Grapy coate where it recedeth or departeth from the horny coate.

n 4, 5, 6, 7, the *pupilla* or Apple of the eye.

o 7, the Ciliat or hairy processes.

p 7, the beginning of the grapy coate made of a thin membrane dilated, but p, in the 17. figure sheweth the ciliar processes sprinkled through the fore-part of the glassy humor.

r 9, the bosome or depression of the glassy humor receiuing the Christalline.

s 12, 15, the bredth of the coate of the Christalline.

t 12, 13, 14, 16, the posterior part of the Christalline humor which is spherically or round.

u 11, 14, 20, the fore-part of the same Christalline depressed.

x 10, 20, the amplitude of the glassy humor.

y 10, 16, 19, the amplitude of the watry humor.

z, 19, the place where the glassy humor is distinguished from the watry by the interposition of the *Hyaloides* or coate of the glassy humor.

a 10, 16, the place where the grapy Coate swimmeth in the watry humor.

β 18, the Cavity or depression of the glassy humor which remaineth when the Christalline is exempted or taken from it.

δ 19, the cavity or depression of the watry humour made by the same meanes.

ment segregated or separated in the nourishment of the Christalline humor, as *Galen* hath written in his Book *de Anatomia vivorum* in the chapter of the eyes, and after him *Columbus*, *Varolius* and *Aquapendens*. *Anicen* also is of the same minde, saving that he calls it the excrement of the glassy humour. And this doubt is further increased, because we learne out of Anatomy that this watery humour is distinguished from the christalline by the cobweb-like membrane, and therefore should seeme not to be the excrement thereof but a part by it selfe.

Whether it
be a spermati-
call part or an
excrement.

But because no spermatial part being taken away can be regenerated, whereas we know that in wounds of the eye this watery humor may be totally lost and yet regenerated again, we are in doubt vpon what we should resolve. *Columbus* saith, that twise he saw this watery humor lost and recovered againe so as the patient could see with the same eye. And *Varolius* affirmeth that he hath seene as much. These learned and curious Anatomists account it but an excrement, which in many diseases is much wasted as *Platerus* admonisheth vs. But *Laurentius* will haue it to be a living and spermatial part of the eye, not an excrement, because it perpetually keepeth the same figure, purity and quantity. Besides, it is a defence for the Cristalline, and like a spectacle carrieth the images thereto. If it yssue out of the eye it can hardly be restored, it extinguisheth the sight, and finally betwixt it and the Cristalline nature hath interposed a membrane.

The cristalline humor [tab. 3. fig. 11, 13, 15.] lyeth vnder the former; so called because it is exceeding bright like pure Cristall in splendor and transparency, but not in consistence and hardnes: and therefore *Hippocrates* in his Booke *de carnibus* calleth it *Diaphanum oculi*, *Aristotle* in the 9. Chap. of the first Booke *de historia animalium* and in the first Chap. of the 5. Booke *de generatione animalium* called it *κόρη* the *Pupilla* or Apple of the eye. This humor is a *Similar* part of the body and made of the most pure and lucide portion of the seede and the sincerest of the mothers blood. That it is a part may be proued as well by the authority of *Galen* as by reason: *Galen* in his sixt Chap. of the first of his Method and in the first Book *de causis Symptom.* reckoneth it among the parts.

The cristal-
line humour.

Whereof
made.

Beside the definition of a part as well generall as speciall agreeth well thereto, for it is generated in the wombe together with the other parts. It hath a proper circumscription. It liueth. It is nourished and performeth an Act or an office: wherefore *Galen* accounteth both this and the glassy humor among the *Similar* parts. This humor in men is scituated right before, [tab. 3. fig. 1. a] for the membrane which containeth it cutteth the eye into two vnequall parts, the forepart being foure-fold lesse then the backpart. Furthermore, it approaches nearer to the inward angle of the eye then it doth to the outward.

His situation

The reason of this position is, because it was necessary that some bodies should be placed before it, others behind it; some of them to be seruiceable vnto it, some of them to defend it, and some of them to lend it their assistance: but in Oxen it is nearer to the lower part of the eye.

Membrane.

It is compassed by the cobwed-like membrane which, as we said, before is fast and polished, but behind more laxe and rare: when this Membrane is taken off the substance of the christalline humour offereth it selfe to our sight, which is waterish indeed, but not fluid, much like water lightly frozen into a tender yce; and when the membrane whereby it is knit together is remooued, it falleth to the sides and slideth a little downe. This humour on the fore side is compassed with the watery humour, [tab. 3. fig. 10. and 16.] on the backside it sitteth or swimmeth rather in the glassy humour as a bowle swimmeth in the water, [tab. 3. fig. 10. and 12.]

The position
Why it hath
no colour.

It is deuoyde of al colour, for if it had bene red or yeallow all things that are seene would haue appeared red or yellow, as it happeneth with those that are troubled with the Jaundies: wherefore, that it might suddainely receiue all kinds of colours which are cast vpon it, it else is of no colour at all but cleare bright & perspicuous, that it might be altered and changed by the light. For this is the onely cause why euery colour hath power to make alteration therein, yea this humor alone is altered by colours and receiue the images of visible things. Yet is not perspicuous or transparant after the same manner that the watery humour is perspicuous and transparant, because in it there is made a new refraction of the light: wherefore it is faster or more dense that the light in his superficies might bee broken *ad perpendiculum* or with a right line, for so the light is better vnited and strengthened. It is moderately hard that the images might be fastened therein, and thicke yet so that it is translucide, that the light may passe through it. It is smooth and notable slippery, and yet with

the softnesse it hath a *Lentor* or sliminesse, so that if you presse it it will cleave like Glueto your fingers. The magnitude of it is much like a lupine or small pease. The figure somewhat flat like a greater Lentile: whence *Aetius* calleth it *parva sive Lenticularis*.

Before it is almost plain, yet a little rising like a Lentile the better to receiue splendor or brightnesse of the light. Backward it is sphericall or round that it might more safely reside in the glassy humor. At the sides it is something protuberated: but because it should not fall out of his seat but hang suspended as it were in the chamber of the eye: it is ioyned to the grapy membrane by the *Ciliar* or hairy ligament, yet that onely in the greatest circumference of the *Christalline*: but before and behinde it is free, that it might not intercept the continuity of the translucid bodies.

The 3. humor
called *Vitreus*.

His situation

Consistence.

And figure.

The third and humor of the eye is called *vitreus*, [tab. 3. figure 1. b fig. 18, and 20.] or the glassy humor, because in consistence and thicknes it is like to melted glasse, in colour and brightnes to glasse when it is cold. It is scituated in the backpart of the eye especially: somewhat also before, insomuch that it filleth the parts of the cavity of the eye if it were diuided into foure [tab. 3. fig. 10, and 20. x] and is foure times as much as is the *Christalline*, the better to containe the spirits of the sight that they should not too soone be disipated.

The substance of it hath a kinde of consistence, establishment or firmitude in it; yet is it farre softer and thinner then is the *Christalline* that it might better giue way therunto, for the *Christalline* is seated therein: notwithstanding it is not so fluide as the watery humor. The splendor or brightnes of it is equall to that of the *Christalline*; for saith *Aquapendens* they are both of a most exquisite purity, transparency and brightnes.

The figure (as it is in the eye) resemblith the better part of a bowle cut in sunder, [tab. 3. fig. 9. and 20.] for the backward surface is round or conuex: the foreward is plaine, yet in the middest thereof hath it a bosome [tab. 3. fig. 9. r and 18. b] whereinto it receiue the *Christalline* humor. And although it bee compassed about by the net-like coate called *Amphiblastroides* whereby it is nourished from the veines disseminated there through; yet notwithstanding it hath a proper coate of his owne called *Vitreum*, which if it bee broken, this humor presently melteth and resolueth into water.

CHAP. X.

Of the use of the Humours of the Eye and of the Sight.

Aphilosophi-
call discourse
of the vse of
the eye.

Auging declared the admirable wisdome providence and goodnesse of God our Creator in the conformation of this diuine member which wee call the Eye: although we haue spoken somewhat in the History of euery particular part concerning their vse, yet there remaine many things worthy our obseruation touching the humors, which being ioyned to that that hath bin saide before will better absolue and accomplish this discourse of the vse of the eye and the true manner of sight. Which though I must confesse that they are more Philosophicall then Anatomicall, yet because they pertaine to the same subiect, I presume the Reader will not abhor from them.

The proper
objects of the
sight.
Common.

Particular
vses of the
parts.

That the Eyes are the instruments of the sight by which it perceiue all visible things as well Proper as Common there is no man ignorant; Proper as all colours, Common as the figure, magnitude, number, motion and scite, which are sensible qualities common to all the Sences; so that it is truly sayed that the Eye seeth not a *Man* but those things which are visible in a *Man*, as colours together with the scite, figure, magnitude, number and motion of his parts, out of which afterward the Soule collecteth that that thing is a *Man*.

The eye is framed of many parts, all which were created for the vse of the sight. But because in euery organe which is compounded of many parts, there is one similar particle vpon which the action of that organe doth especially depend, it would bee knowne what this particle is in the eye: we answere that it is the *Christalline* humor which is the author of the action, because in it the species or formes of visible things are receiued and by it iudged of.

Beside this, there are some particles without which the action cannot be; as the opticke nerue which leadeth along the faculty vnto the *Christalline*; some also by whose helpe the action is made more perfect, as the membranes and the muscles: and finally, some particles are ordayned for the conseruation of all these, as the Eye-lids and the parts about them.

Seeing therefore the faculty is deriued from the braine by the opticke nerues vnto the eyes,

eyes which are set as scout-watches to take knowledge of the ariual of outward things; that they may better apprehend the knowledge of such outward objects, it was necessary that whatsoeuer is to be perceiued should touch the nerue: for *Aristotle* sayeth in his third Booke de *Anima*, That euery action is made by contaction.

This contaction is here made by a *medium* or meane; for the Sences doe perceiue their objects through a meane. Wherefore seeing the nerue is separated from the visible object, that there may be sight it is necessary there should be a contaction and application either of the nerue to the object, or of the object to the nerue, or else that either of them should be moued in a certaine proportion to the other.

The two first wayes it cannot be, as euen Sence it selfe teacheth vs, & therefore it must be done the third way. If vision be made the third way, then eyther something must proceed from the nerue to the visible objects, or on the contrary something must be sent from the objects to the nerue, or else both must be: that is, Sight must be made either by an emission of spirits, or a reception of beames, or else by emission and reception both together.

Now the spirit is not carryed from the nerue to the thing that is to be seene, for then it would follow that the nerue alone by which the faculty yssueth can absolute and perfect the action of sight, and the iudgement should be made without the eye. Againe, neyther is there any corporeall thing transported from the body which is sent vnto our eyes; for then the objects by continuall diffusion would be deminished. Neither is Vision made the third way, for that a spirit or a beame or a light should yssue out of the Eye vnto the object: and againe something of the object should bee moued vnto the spirit, that so the contaction might be made in the middle, for then the nerue alone would haue sufficed for the action, and the iudgement should haue beene made without the eye. Wherefore we thinke with the Philosopher that this contaction is made by a *medium*, so that a certaine quality with some colour affecting and changing the ayre that is cleare and lucid betwixt the eye and the object doeth transference from the things themselves, the visible *species* by one right line from the object to the eyes, yea to the center of the Christalline humour. So the ayre which is in the middest betwixt the eye and the object leadeth along that which is perceived and first of all the colour; for the ayre is altered by colours which it receiueth by contaction; for euen as the Sunne attayning by the brightnesse of his light vnto the Element of the ayre illustrateth the same; so coulours when they touch the ayre make a kinde of impression therein, for the ayre is alwayes capable of colours when it is cleare, light and illustrated by the brightnesse of the Sunne beames. Vision therefore or sight is made by the reception of visible formes, when the light affected with those formes entreth into the eyes through their translucid bodies. First of all with right beames, afterward diuersly refracted or broken and affecteth the Christalline with some colour, which Christalline as the primary instrument of sight doth in an instant receiue those visible formes whereof refraction is made in the membranes, a perfection in the coniunction of the optick nerues, and finally a perception in the braine. For the light is the proper object of the sight whereby it is moued and affected; Light I say stayned with the formes of colours and external light, for the eye of a man hath not in it any In-bred light, for then he might see in the darke by sending out a light from his eye. Albeit *Suetonius* reporteth that *Tiberius Caesar* had such an eye, and that excellent Philosopher and Physitian *Cardan*, as also *Iohn Baptista Porta* of *Naples* do affirme the same thing of themselves. Some creatures there are we know which see worse in the day time then in the night, and therefore they seeke their food in the night season.

Now because the light thus affected with the images of visible things, must passe through a refraction of his beames, it is necessary there should be diuers translucide bodies. First the ayre through which it attayneth to the eye, then water in the eye in which this refraction might be made. *Plato* indeed who thought that sight was made *extra mittendo*, or by an emission of light out of the eye, thought that the nature of the eye was fiery, yet not such a fire as would burne but onely illustrate; for saith he there is a threefold fire: one shining and not burning, another shining and burning, and the third burning and not shining. But we are taught by Anatomy and by the whole composition of the eye, that the instrument of sight is watery, and therefore *Hippocrates* in his Book de *locis in homine*, saith that the sight is nourished, that is increased by a moist braine. And hereto also may we adde reason, for it is the property of water to receiue; wherefore seeing the formes and images of outward objects must be receiued, it is necessary that there should be water in the eye.

All sense is by contaction.

How many wayes contaction is made.

How sight is made.

Whether in mansie there be an ingenit light.

Tiberius Caesar
Cardanus
Iohn Baptista
Porta

Plato thought the eye was fire.

A threefold fire.

But

How the
formes are re-
tained.

That there
are 4. refractions of the
light in the
eye.

6. in a paire
of spectacles.

Another vse
of the watery
humor.

A third.

A fourth.

A fift.

A sixt.

The vse of
the cristalline
humor.

An axiome in
philosophy.

But because these visible formes should not onely be received, but also retained in the eye, it was necessary that the body of the eye should be made not onely translucent but also dense and fastly compacted: wherefore Nature did not only make the eye watery that there might bee a refraction, but also that this refraction might bee manifold: shee hath created translucent bodies of diuers consistences; for the watery humor is indeed translucent and admitteth the light yet the *Diaphanum* or transparency thereof differs from the transparency of the horny membrane that there might be also a different refraction; this refraction is made from a perpendicular and is in the eye foure-foulde. The first is from the ayre into the horny membrane which is a faster *Diaphanum*. The second from the horny membrane into the watery humor which is a thinner *Diaphanum*; in this watery humor the light is vnited and made stronger, so that it is able to pierce through the third *Diaphanum* which is the cristalline humour, wherein as in a faster substance the light is yet more strongly vnited and so passeth on to the last refraction at the glassy humor of which we shall speake by and by. And as in the eye naturally disposed there are foure refractions, so in the spectacles which make the object both larger and brighter there are sixe. For first of all the light entred into the spectacle which is a thicker *Diaphanum* from the ayre which is a thinner, from the spectacle before it come to the eye it passeth through the ayre again which is a thinner *Diaphanum* into the horny membrane which is a thicker; from the horny membrane into the watery humor which is a thinner *Diaphanum*, from thence into the Cristalline which is a thicker, and finally into the glassy humor so that it proceedeth by course out of a thinner *Diaphanum* into a thicker.

Another vse of the watery humor is to fill vp the empty space betwixt the Cristalline and the forward membranes, as also to keep the horny membrane streatched or tentered and moyst, least if it should grow dry it might be corrugated or wrinkled, and so become thicker and hinder the reception of the visible formes.

Thirdly, the watery humor sayth *Galen* in the sixt Chapter of his 10. Booke *de usu part.* keepeth the horny membrane, the grapy membrane and the Cristalline from exiccation: because the moysture thereof keepeth them transparent without which there could bee no vision at all, for we see that in compunctions or wounds of the eye; when this watery humor is let out and dried vp, the horny membrane which before was turgide and full falleth into it selfe and becommeth darke and rugous.

The fourth vse of the watery humor is to be a defence vnto the Chrystalline, least the horny membrane should touch the Cristalline through the *Pupilla* and offend it with his hardnesse.

The fift vse is to restrain the impetuous or violent occursion or confluence of external colours vnto the Cristalline.

And finally to eleuate or lift vp the formes of visible things as spectacles doe, that they might be more fully and directly perceiued by the sence. For when the images of external things are ariued at the narrow hole of the *Pupilla* they are lifted vp and so exhibited in the watery humour, wherein they are made more perspicuous; and this indeede was the chiefe reason why Nature placed so pure and neate a humor before the cristalline, which is the prime instrument of the sight.

The vse of the Cristalline humour is to be the first and chiefe instrument of the Sight, as wherein it is perfected, and therefore some haue called it the Idol or image of the sight, and *Aristotle* calleth it *Pupilla*, haply because we see especially right before vs. That it is the chiefe instrument of sight may thus be demonstrated. The Philosophers say, *That whatsoever is made to receiue any thing must be utterly free from the nature of that which it is to receiue, because the same thing can neither worke upon it selfe, nor suffer from it selfe.* Wherefore that which is the proper Organe or instrument of Sight must haue in it no colour at all, because it is to receiue all colours. And indeed hereby may we perceiue a thing to be without colour, when if it be placed against any colour it representeth the same, as it is in ayre, water, Crystall and such like: wherefore the instrument of sight must either bee airy or watery, or cristalline.

Airy it might not be, because the colours that are receiued in the ayre do flow through it, making no mutation at all therein, but we know that the instrument doth onely then perceiue and apprehend the object when it so suffereth therefrom that it is made the very same; seeing therefore that the colours doe passe through the ayre and make no mutation therein, it could not be that the instrument of Sight should be airy.

In

In the second place it could not be watery, for though the species and formes of colours make a deeper impression in the Water then they do in the Ayre: yet are not the colours therein so imprinted that a man may behold them in it, but they flow through it also. It remaineth therefore that the instrument of sight must bee Christalline, because that onely can receiue and retaine the visible formes. And this also may be proued by *Autopsie* or ocular inspection, for if you take a beade of Christall and set it opposite against a coloured body, which way soeuer you looke, you shall see the colours in the christall, as if the christall were of the same colour, and did not receiue the impression thereof from those coloured bodies. Wherefore in the Christalline humor colours are not only receiued but also so retained that the power thereof is changed into the colour which it receyueth.

Nor watery.

And the reason hereof is, because there is in the christalline not only a watery moysture, but also a glutinous or slimy, which with his lentor and tenacity retaineth the images or formes of the colours.

But christalline

The chiefe instrument therefore of Sight Nature hath placed within the eye, to weete, a round and gutinous humor most like vnto christall to receiue and retaine the representations of all colours. This christalline humor if you duely consider when it is taken out of the eye you shall perceiue it hath no colour in it, but will represent any colour layde neere it, as if it were of the same colour.

Moreouer, if you cut this Christalline humour in sunder, you shall finde that it is made of a glutinous and slimy moysture. And because sensation is a kind of reception, therefore was the christalline made round.

The action also of the Christalline humour is assisted by the cobweb-like membrane which compasseth it about, for if you take out the christalline humor compassed with his Membrane and lay it vpon a written paper, the letters vnder it will appeare much greater then indeed they are, from whence haply came the inuention of Spectacles, and indeed this humour is a very spectacle to the Opticke nerue, gathering the species which fall vpon it and representing them in a larger forme vnto the nerue.

The christalline humor is a spectacle to the nerue.

Sight therefore is perfected and absolued, both by alteration and apprehension or discerning. The alteration is made in the Christalline by reason of the transparency thereof; yet is this transperencie of another kind then that of the watery humour, that it might bee both altered and also changed by the light. For that the impression might be more firme, it is thicker then the watery humour, that in the superficies thereof the sight might bee broken *ad perpendiculum*: for so the light is stronger vnited and corroborated when the beames are obliquely shed abroad and yet meete together againe into one because of their refraction; wherefore the Christalline humour is thicker then the other transluide bodies that are in the eye, as the horny membrane, the watery and glassy humours; because it was made not onely to returne and giue way to light and colours, but also to deteyne them, to suffer from them, and to receiue a sensation of visible things: for the thicknesse thereof prohibiteth the transition or vanishing away of the formes which are fixed in the superficies and body thereof. For sense is not made without passion or suffering: now it could not suffer vnlesse the action of the Agent had bene receiued vnto it. Notwithstanding, it is not so thicke or hard that the species or formes could not bee imprinted therein, but soft like vnto waxe and viscid that they might cleaue faster thereto. Hence it commeth to passe, that when a strong light, as that of the Sunne, beateth vpon the Christalline it is pained and offended, because the image of the light maketh a kinde of abode therein. But naturally the image of visible things are no longer retained in the Christalline then is necessary for their perception, but giue way to others: otherwise the sight would bee imperfect: for before the former images be vanished the succeeding cannot bee admitted, because the alteration remaineth in the Christalline vntil the representation acquit the place; when that is gone the alteration vanisheth together with it, and so there is way made for a new alteration.

How sight is perfected.

Why the christalline is thicke.

Why soft.

The conformation also of the Christalline helpeth much to make the sight perfect, for example. It is smooth and polished, that the formes therein might be most like to the bodies from which they are deduced. It is round that the light and the perpendicular beames thereof might in it be better vnited, and againe, that the light might be gathered in his superficies where the sensatiue facultie is the strongest, for so the formes euen of the greatest objects are conuayed whole vnto the Organe. Notwithstanding on the foreside this roundnesse is somewhat depressed, which depression helpeth much the reception of the formes.

The reason of the conformation of the christalline.

On

On the backside it is rounder than the light being brought vnto the Christalline might be vnited in it selfe and not disparted, but determine and subside in the glassy humor.

The reason of
his connexion.

The use of the
glassy humor.

The Christalline humor also before and behind is at liberty or free from connexion, that the light which entreth alway directly, might haue free passage through all the transluce bodies of the eyes, for by this meanes whatsoever is betwixt the Christalline humor and the thing seene is continuat by a continuity of transparency. Yet ought it not to bee on euery side loose, because then any extraordinary motion might haue violated the frame of the eye. Nature therefore hath hidde it in his circuite to the neighbour parts, and scituated it in the midst; that it might receiue the ministry of all the rest.

The glassy humor is seated after the Christalline, least if the light should haue passed on to the Net-like and Grapy Membranes which are coloured, it should haue returned againe to the cristalline defiled with those colours, and so the sight haue beene forestalled by those inward colours which are neere vnto it. Againe, at this *Diaphanum* of the glassy humor, there is a new refraction made of the light, not such a refraction as is in the Christalline whereby the light is more vnited, but because the substance of the glassy humor is more rare and thin, the light therein is dispersed and weakned, some say also vanisheth, others that it reacheth from thence into the cavity of the Opticke Nerue where the sight is perfected, and surely the finenes of the net-like Membrane is not able to returne the light that beatech against it, but rather giueth way thereto.

Galen credit
redemed by a
distinction.

How the chris-
talline is nour-
ished.

Another use of the Glassy humor saith *Galen* is to nourish the christalline, which it doth *per Diadosin* or transumption, for he thought that the christalline humor could be nourished by blood. But to saue *Galen*'s credit, we must heere distinguish, for all parts are nourished by blood; now the Christalline is a part and therefore it is nourished with blood. We answer, that it is not immediately nourished with blood but mediately, for because there are no Veines neyther in the christalline nor in the glassy humors (at least that the sight of man is able to apprehend) blood cannot be conuayed vnto them; neyther indeed ought it least it should haue infected the Christalline with a redde colour, which would haue beene a great hinderance to the sight, for it behoued aboue all things that the christalline should be free from all colour, because it was to receiue all. Wherefore it was necessary that his Aliment should bee prepared and not conuayed vnto him before it were fitted for his use.

The blood therefore conteyned in the Veines of the Grapy Membrane in which it is thicke and blackish is powred forth into lesser branches running through the Net-like Membrane, where it receiue an alteration becomming very thin and of a cleare ruddinesse, which blood is receiued by the glassy humor therein prepared and made a fit Aliment both for it selfe and for the christalline. Hence it is *Galen* saith, *The Glassy humor to the Christalline is like the stomacke to the Liuer.*

Diuers opini-
ons concerning
the nourish-
ment of the
christalline hu-
mor.
Galen's opini-
on.

But because Anatomists are of diuers opinions concerning the nourishment of the Christalline humor, it shall not be amisse to giue you a taste of euery mans apprehension in this matter, especially of those that are accounted Maisters in Anatomy.

Galen therefore in the first Chapter of his 10. Booke *de usu partium* saith, that the christalline humor is nourished by the glassy, and the glassy by that body which compasseth it about, to wit, the Net-like Membrane, and that *per Diadosin* or a transumption of matter, because (saith he) the christalline humor which is white, cleare and resplendent ought not to be nourished by blood, as whose qualities doe differ much one from the other, whereas the aliment should be familiar to that which is nourished thereby. Nature therefore prepared for it a proportionable aliment, to witte, the glassy humor, which glassy humor by how much it is thicker and whiter then blood, by so much doth the Christalline humor exceede it in humidity and whitnesse, for this christalline is exquisitely white and moderately hard.

Varolius.

Varolius enclineth to *Galen*'s opinion, his words are these or at least to this purpose. Euery thing is nourished by such a substance as determineth neere vnto that which it should nourish, and therefore the glassy humor is immediately placed behind the christalline, and is of a softer and a thinner consistence, also because so noble a part which needeth such abundance of spirits for continuall expence should not at any time be defrauded of nourishment, Nature made so great a quantity of the glassy humor; in which nutrition the Chrystalline turneth into his owne nature the thicker parts of the glassy humor because it is farre thicker and faster then it. But the thinner part of the glassy humor she separateth

as an vnprofitable excrement from the CrySTALLINE, and thereof maketh the watery humor. Thus far *Parolius*.

But saith *Archangelus* (who thinketh that the Christalline is so nourished with the glasse humor as a bone is nourished with the marrow) if the Christalline and glasse humours be parts of the body, then one part shall nourish another? But it may be answered, that there is a surplussage of the nourishment of the glassy humor which is a conuenient Aliment for the Christalline. Another question may be asked, saith hee, how *Galen* saith that in the glasse humor there is no veine? It is answered that there is no veine conspicuous, but yet there are very many which are so slender that the eye cannot discern them, and hence it is, that the glassy humor is not so white as the Christalline, because it is sprinkled with many blinde veines. In like manner in the white of the eye which is called *Tunica Adnata*, there appeare no veines at all, but if the eye bee inflamed, then many veines which before lay hid doe arise vp and become conspicuous. If the braine of a man be dissected, there appeare no veines therein, but if it be inflamed, then, saith *Archangelus*, may an infinite multitude be perceiued to run through his substance.

Archangelus.

Archangelus conceit.

Laurentius conceiue that the glassy humor is nourished by blood, and receiue small veines from the *Ciliar* or hayry crowne; and that the glassy humor prepares the blood for the Christalline, which blood it changeth least the purity of the Christalline should be infected, but he doth not thinke that the substance of the glassy humour is conuerted into the Christalline and assimilated thereto.

Laurentius

Aquapendens his opinion is, that the christalline is nourished by blood, and that as bones and membranes which are very white and farre remooued from the Nature of blood by a propriety of their temperament doe change the blood into their substance: so it commeth to passe in the christalline humor; and that the blood is conuayed out of the veines of the grapy into the net-like coate and there depurated that it might better be conuerted into the nitid and pure substance of these bodies. The thicker part is thrust downe into the grapy coate and there collected. The thinner part maketh the watery humor. Neither doth hee thinke it possible the christalline should be nourished by the glassy humor, *per Diadosin* or Transumption, because the cobweb-like membrane commeth betweene the two humours, which *Galen* was ignorant of, who thought that the forepart onely of the Christalline was couered, and from that mistaking fell into that error of nourishment by Transumption. And so much concerning the nourishment of the humors.

Aquapendens

Two other vses there remaine of the glassy humour, the one to retaine the spirits for the illustration of the Christalline, the other to defend it from the hardnesse of the membranes, and to make it a seat wherein it might securely rest it selfe.

Other vses of the glassy humor.

CHAP. XI.

Of the outward Eares.

 Auing thus absolued the history of the Eye, it followeth that we come vnto the organ of Hearing, which *Aristotle* calleth *Sensum disciplina*, because it was created for the vnderstanding of Arts & Sciences: for Speech because it is audible, becometh the Cause of that we learne thereby, as the Philosopher saith in the first Chap. of his Booke *de Sensu & sensili*. This instrument of Hearing is the Eare, framed by Nature with no lesse Art then the former. Yea so full of intricate Meanders is it, that it wil be very hard to be disciphered, so many and so small are the particles thereof, and couched so close in narrow distances or nookes betweene the bones. Notwithstanding wee will endeavour our selues for your satisfaction to acquaint you what we haue learned, as well by dissections as out of the writings of learned men, especially *Fallopins*, *Eustachius*, *Volcherus*, *Arantius*, *Aquapendens* and *Placentinus*. But in the pursuite of this so difficult a taske, we stand in neede and do implore the helpe of Almighty God, that he would set an edge vpon my wit, sayth *Bauhine*, to find out the miracles of his Creation, the Diuinity of his wisdom, and the infinite goodnesse wherewith he hath compassed vs on euery side. Moreouer, that he would giue me power perspicuously to propound and lay open to your capacities a thing so diuersly and quayntly folded vp, that the Eye is scarce able to follow the trayne thereof.

The history of the eares very difficult to expresse.

These instruments are called in Greeke, *ᾠτα & ᾠταρα*, in Latin *Aures ab hauriendis vocibus*, as saith *Lactantius*, in English, *Eares*, of hearing.

The names of the eares.

There are many parts of the Eares which serue as well for the reception of the sound into them, as also for the *intension* thereof. Some of them are such, as without which there is no reception of sounds, others are necessary for better reception and hearing. Finally, others were created for the conseruation of all the rest. We will diuide the Eare according to *Hippocrates in Coacis* into an outward and inward Eare, and first wee will entreate of the outward.

The reasons of
the name.

The Eares saith *Aristotle* are parts of the head by which we heare, and therefore it may be imagined they are called *Aures quasi aures, ab audiendo* from hearing. Instruments they are of Hearing indeed, as *Galen* confesseth in the second Chapter of his Booke *de Instrumento Odoratus*, but not the principall organs, because if the Eares be cut off close by the head, yet a man will heare notwithstanding, as if the nose bee cut off a man shall smell though imperfectly.

The reason is, because the principall instrument both of Hearing and of Smelling lies hid within the scull. The outward Eares therefore are helping causes, and when they are sound and whole they are of as great vse for the Hearing, as the nosethrills are for the Smelling.

These outward Eares properly called *Auriculae* are in men and beasts conspicuous, but in Birds and Fishes it is not so, for Birds haue onely holes whereby the sound entereth into their Braines, because their skin being harder they want matter whereof this Eare should be framed; beside, such eares as other creatures are furnished with, would haue beene a hinderance vnto them in their flight, as we see a contrary winde blowing vpon a saile stayeth the course of a Ship: as for Fishes no man that I know hath yet found out the instruments of their Hearing. Those holes which are placed before their eyes wee doubt whether they serue for Hearing or for Smelling.

What crea-
tures want
outward eares.

The outward Eares are placed in the same paralel or line with the eyes, yet not so much for the better reception of sounds, which saith *Cicero* in his second Booke *de Natura Deorum*, of their owne nature do ascend vward because they haue their consistence in the ayre; but rather from the commodity of those soft nerues within the scull which were to communicate the animall spirit disperfed through the substance of the Braine vnto the principall Organe of Hearing. Otherwise if the eares had their scituation onely for the apprehension of sounds, they might as well haue beene placed in any part of the Creature as where they are; because sounds are equally communicated to the whole ayre that compasseth vs about. But on the foreside they might not be placed, because that roome was to bee taken vp for the eyes and the instruments of other senses. For the Eyes, because we see by a right line; but we may heare as well on either side as directly forward, as *Aristotle* saith in the tenth Chapter of his second Booke *de Partibus Animalium*; although I am not ignorant that *Galen* in the eight Chapter of his tenth Booke *de vsu partium* is not altogether of *Aristotles* opinion.

The reason of
the situation
of the eares.

Againe for the Mouth, partly for the commoditie of receiuing meates and drinckes directly from the hand, partly also because it was fit wee should turne, not our eyes onely but our mouth also toward them with whom we discourse.

Thirdly for the Nose, that the saouours of meates and drinckes which we iudge and discern whither they be good or ill might more directly strike the sense of Smelling. Moreover, the Eares were not placed in the backpart of the head because there are no Nerues deriued thereunto; not in the top of the head least the couering of the Head should hinder the ingresse of the sound. It remaineth therefore that it was most conuenient they should be placed in the sides of the head or the face iust against the region of the eyes, and also be in man immouable. In brute beasts their scituation is somewhat otherwise, to wit, at the toppe of the Face, because their heads hang alwayes downeward vnto the earth to seeke their Food. In Beasts also the eares are moouable.

Apes Eares.

The Eares of Apes haue a middle position betwixt those of men and beasts, because it is a creature of a middle figure betwixt the erected frame of a man and the prone or bending posture of a beast. And as their position so likewise is their motion, not immouable as in Men, nor so moouable as in other beasts, but betwixt both.

Their Figure.

The figure of the outward eare is round or semi-circular [table 4. Figure 1. F, Table 5. fig. b b, Table 6. Figure 7. 1.] because that which is round is best secured from iniuries, as also most capacious. On the outside they are conuexe or gibbous. On the inside excauated like a denne

TABVLA IIIII.

FIG. I.

FIG. II.

AA, The skin of the head together with the rootes of the eares.

BB, The muscle of the eare springing from the *Pericranium* or skul skin.

C, The triangular muscle moving the skinn of the nowle of the head.

DD, Branches of the externall iugular veine.

E, The tip of the eare.

F, The circumference of the eare called *Helix* in Greeke.

G, The glandules of the eares, in which is the disease called *Parotitis*.

The second Figure.

A, The semicircular muscle of the eare drawing the outward eare vpward, which was noted with *B*, in the first figure.

BCDEFG, the muscle as it were diuided into 3, parts called *Triparsitus*.

H, the hinder part of the outward eare, into which the foresaide muscle is fastened.

IIII, the circumference of the eare called the wing.

K, the lap or tip of the eare.

L, the little gristle on the outside of the hole of the hearing, which in ancient men is bearded, called *Tragus* because it is like a Goates beard.

MMM, the skull as yet couered with the *Pericranium* or skul skin.

NNN, the circumference of the temporall muscle.

O, the muscle yet couered with the *Pericranium*.

P, the membrane, couering the said muscle drawne aside.

QQQ, the fleshy part of the temporall muscle.

RR, the iugular or yoke bone.

SS, A sharpe proceffe of the lower iaw.

V, the muscle *masseter* or grinding muscle, remooued heere from the yoke bone whence it hath his originall, that the implantation of the temporall muscle into the proceffe of the iaw might appeare.

X, the muscles making the Cheeks.

Y, Fleshy Fibres going vnto the lips.

Z, A muscle of the lower lip. *aa*, the muscle of the eye-brow. *bb*, the vpper eye-lid hauing a muscle with transuerse Fibres. *c*, the eye brow hauing a circular muscle, whereby the externall parts of the eye are exceedingly constringed, as saith *Iulius Casserius Placen*.

den or cornered hole. Yet euen on the inside there are certaine swellings answerable to the cavities, to breake the violent rushing of the ayre or wind or whatsoever should vnawares be offered against them. For in these breaches of the eare as it were in hollow bodies, not only the sound of the ayre that rusheth in is readily and exactly drawne and fully receiued; but also it is broken and boundeth or reboundeth as a ball against the sides of the inequalities till the refraction get into the circular cavity and so the sound becomes more equall and harmoniacall. It attaineth also better vnto the Tympane or drum of the eare without trouble or molestation, and is imprinted vpon or into the inward ayre more strongly and more distinctly; and beside, by this meanes the sound continueth longer as wee may haue experience if we apply any hollow shell to our eares, for by that meanes the ayre is better gathered and more directly offered to the auditory nerue. The *Schythians* that liue in the cold Northernly countreyes haue often their eares rotted off with cold, whereby their hearing is much impaired to, amend which default they fasten about the hole some hollow shell; imagine it be of a great Cockle or Scallop wherein the ayre is concluded; gathered and directed vnto the head.

The truth hereof may be diuersly demonstrated, first because all sounds are most exactly receiued in hollow and hard bodies, as bells and such like. Againe, those men whose eares are cut away do receiue sounds and articulated voices after an obruse, dul or confused manner.

Ddd

ner

The reason thereof.

How the *Schythians* make amends for the r. ting of their eares.

ner like the fall of water or chirping of a Grashopper, inso much that the other eare which is not vitiated is notwithstanding impaired, vnlesse that which is wounded bee quite stopp vp.

Adrian the
Emperour.

Finally, such as are halfe deafe that they may heare the better, do set their hands to their eare with the palmes forward to gather in the sound, as we reade that *Adrian* the Emperour was wont to do. Another vse of this refraction of the aire is, least it should enter into the Eare too cold if it were not broken and beaten against the sides in the passage whereby it receiue if not heate yet a mitigation of his coldnesse. And finally, if it were not for these breaches many violent sounds would suddenly rush into the eare to the great offence of the Hearing.

The magnitude
of the Eares.

These Eares are not alwayes of one magnitude, but in some greater in some lesse, but most what proportionable to the magnitude of the body, and yet it hath beene obserued that where there is greater store of vitall heate there the eares are some what the larger. Howsoeuer, they are small in man in respect of other creatures, as well for ornament as because the head of a man (saith *Galen* in the 12. Chapter of his 11. Booke *De vsu partium*) was to be couered eyther with a hat or a head-peece or some other couering; wherefore if mens Eares had bene as bigge as beasts it would haue bene very inconuenient, yet they are large enough to cover the passage.

Why they are
two.

They are made double, not so much that when one is vitiated we might haue vse of the other (although this bee a great commoditie) as for the necessity and perfection of the Sense.

The diuision
of the outward
Eare.

The whole Eare which *Vesalius* not vnfitly compareth to a fanne wherewith they dresse Corne, may fitly be diuided into an vpper and a lower part. The vpper which is hard and as it were stretched *Aristotle* in the 11. Chap. of his first Booke *de historia animalium* leaueth without a name, but *Gaza* his interpreter calleth it *pinna* [tab. 4. fig. 1. tab. 5. b b] the Finne, as well because of the forme as also in respect of the vse: for the Forme, because that broad Gristle is not vnlike the Fin of a Fish: for the Vse, because as the fish guideth her selfe in the water with her Finnes, so these gristly parts cleaving to the sides of the head do guide the sound that it passe not away before it is communicated to the *Inward Aire*, and for the same cause it is called by some *πτερόγυμα*, that is, a wing; broad it is the better to entertaine or catch the sound which afterward descendeth by the inward compasse vnto the arched cavity that leadeth vnto the passage into the head.

The wing or
fin of the ears.

The Lappe of
the eare.

The lower part which is soft and depending [tab. 4. fig. 1. E fig. 2. K, tab. 5. fig. 1. a] is called *λαβός ἀπὸ τοῦ λαμβάνειν*, because we take hold of that when we wold admonish a man, and thence haply it was that the eare is consecrated to Memory. The Latines call it *Fibra*. *Tully* in his second Booke *ad Quintum fratrem* calls it *Ansa Auriculæ* the handle of the eare, we call it the Lap of the eare, because it is a softe and flexible body, hauing in it neyther bone to stiffen it, nor gristle to harden it, nor Nerve to stretch it, and therefore it may be perforated without paine or with very little, as we may see in young folkes of both Sexes, who vsually hang Jewels at it. *Laurentius* well obserued, that it is a signe of modestie or shamefastnesse, because vpon such a passion this part will grow redde. But the naturall vse of it is to conduct the excrements downward which yssue out of the eare.

The severall
parts of the
outward eare
and their de-
nominations.

The outward circumference of the eare is called *ἐλξ Capreolus* of the likenesse it hath to the writen Tendrill of a Vine. [tab. 4. fig. 1. F F. tab. 5. fig. 1. b b] The inner compasse, which is as it were opposite to the vtter, is called *ἀρτέλιξ*. *Pollux* calleth it *Scapha*, because it is somewhat like a Lighter or Barge. [tab. 5. fig. 1. CC] The great cavity which is compassed almost round by this inward circumference [tab. 5. fig. 1.] is called *Concha*, because it is like the shel of a Periwinkle and this is the principal part of the outward eare made so large that it might receiue all the sound which runnes within both Circumferences, but the cavity thereof groweth narrower toward the hole of hearing, that the sound being gathered into a narrower scantling might more suddainely and at once be offered vnto the Organ.

But the Cavity which is next vnto the hole of Hearing wherein the eare-wax is, is cald *αὐτίαν Aluearium*, & the bitter waxe it selfe *Αφροδίσαν* calls *αὐτίαν*. That eminence which is opposite to the hollownes [tab. 4. fig. 2. L, tab. 5. fig. 1. C] toward the temples which hangeth like a pent-house over the hole of the eare is called by *Ruffus* and *Pollux* *τράγος Hyrcus* the He-goate, because in this part there grow haire which in some men are so rigid and stiffe that they are like a Goats beard.

The part opposite hereto, to which the lap grows, sometimes is also hairy, [tab. 5. fig. 1. f] and

Tab. 10. sheweth the eares and the diuers internall parts thereof.

Figure 1. sheweth the whole externall eare, with a part of the Temple bone.

Figure 2. sheweth the left bone of the Temple diuided in the midst by the instrument of hearing, whereabout on either side there are certaine passages heere particularly described.

Figure 3, and 4. sheweth the three little Bones.

Fig. 5. sheweth a portion of the bone of the temples which is scene neere the hole of Hearing diuided through the midst, whereby the Nerves, Bones and Membranes may appeare as Vesalius conceiueth of them.

Fig. 6. sheweth the Vessels, Membranes, Bones and holes of the Organ of hearing, as Platerus hath described them.

Fig. 7, and 8. sheweth the little bones of the hearing of a man and of a Calf both ioyned and separated.

σ, the Anuile. τ, the Stirrop.

and called *ἀντίπαγος*. The vse of both these is to forme the cavity and to hinder the sweat or any such like excrement or outward thing from falling into the eare. Betwixt these two there is a hollowed furrow like halfe a circle, which *Herophilus* calleth *ἐχμῆς* and *Pollux* *ἐχμίσχος*, into which the excrement or whatsoever yssueth out of the eare falleth before it get into the large cavity and so fall away by the lap.

The vse of
the outward
eare.

The vse of the whole outward Eare which like a Fan is dilated, was especially to intercept the species of sounds wandering through the aire, and to gather them as it were into a bosome, or if you will, into a broad tunnell to be conuayed by manifold breaches or returns to the hole of the Eare. Againe, the many oblique furrowes in the outward eare doe breake the violence & force of the ayre, which otherwise might haply loosen or breake the fine membrane of the Tympane or drumme. There are also certaine bunching protuberations where the gristle swels vp into a prominence, which prominence, if the aire doe passe the hole of hearing, beats it backe againe forward toward the cavity. For because the holes of the Ears are placed in the sides of the head, the sound may easily slip by them, especially when it commeth from behind vs and we moue forward, if it were not caught in these conuolutions and in the guttures of the gristly substance conueyed vnto the hole of hearing.

And hence it is that euen by instinct of nature we see brute beasts, as Dogges and Horses will pricke vp their eares, and partly turne them toward any sound or noyse that is made. And because the Eare might be thus prominent, as well in the parts as in the whole (for the whole eare standeth of a certaine distance from the head,) Nature hath made them of a Cartilaginious or gristly substance, which out of doubt would grow farther from the head if Nurseries or carefull mothers who haue more respect of comelinesse then of vse, did not bind them downe in our infancy.

A fitt simili-
tude expressing
how the sounds
come through
the aire vnto
the eare.

If you aske me how the sound of any thing farre off can ariue vnto the eare; I will answer by a pregnant example on this manner: If a stone be throwne into the midst of a pond, it moueth the water in circles, one alwayes succeeding greater then another vntill the motion determine in the brinckes or bounds of the pond: so in like manner those bodies which by their collision do make a sound, mooue the ayre into orbes or circles succeeding one another, so that the circles which are nearest to the body from whence the sound came are but small, the rest which follow them grow greater and greater vntill they come vnto the eare, whereat when they beate they are latched in those furrowes we spake of, and by them directed vnto the hole of hearing.

CHAP. XII.

Of the Parts of the outward Eares.

His outward Eare is made of parts, some common, some proper: the common parts are the cuticle, the skin, the fleshy membrane, flesh it selfe and a little fat in the lobe or lap. The proper parts are muscles, veines, Arteries Nerues & a gristle.

The cuticle or skarfe-skin we haue spoken of before in the second booke, as also of all the other common parts; onely of the skin it selfe in this part we may say, that it is exceeding thin, yet somewhat thicker in the gibbous or backside of the eare then it is in the concave or foreside, and the nearer it comes to the hole of hearing, the thinner it is. This skin compasseth the eare round about, both without and within, and cleaueth very strongly and firmly to a little flesh and to the gristle, that the superficies of the eare, especially the inner might be smooth and slicke, not corrugated or vnequall, as well for beautie and comelinesse as also for the better reception of sounds: for *Aristotle* in the 7. Probleme of the 11. section, enquiring why a house that is new plastered doth sound better then an old house? answereth, that the reason is, because the wals are smooth, which smoothnesse proceedeth from density or fastnesse. It is reasonable therefore to thinke that the smoothnesse of the eare helpeth the sound, and theretore the very hole also of hearing is inuested with a thigh, hard, thin and smooth skin, which cleaueth very closely to the membrane there vnder. But where the skin incompasseth the lobe or lap of the eare, it is so exquisitely mixed with the membrane and the flesh that it cannot be separated from them; and therefore we may call that part a fleshy, fatty and spongy skin.

The skin of
the outward
eare.

NNN 4, 5, The semicircles.
O 4, 5, The inner face of the snayly shell called *Cochlea*.

DDD] from the externall *Iugular* as also from the lesser branch of the internall *Iugular* veine which entreteth into the Basis of the scull through the fourth hole of the Temporall-bones. There is a small branch also directed to the Organ of Hearing and into the first cavity [tab. 3. lib. 7. fig. 13. n] which bringeth bloud for the nourishment of the parts containd, and haply also of the ingenite or in-bred ayre. And that there are veines deriued into this cavity, and vnto the membrane or drum, may be proued by the dissection of those bodies that dy of an inflammation of the braine or of the eares. For if the hole of hearing be featly opened, you shall find small veines conspicuous in the membrane or Tympane, which do not appeare when there is no inflammation, as we said lately it hapneth in the white of the eye.

Arteries it hath from the inner branch of the *Carotis* or sleepy Artery which passe to the backside of the Eare [tab. 13. lib. 6. O] that those parts and the in-bred ayre also might be refreshed with vitall bloud and spirits.

Two small nerues it hath from the backward, and two from the sides of the second coniugation of the marrow of the necke; and these are very small, sayeth *Galen* in the 6. Chap. of his 16. Booke *De usu partium*, in Men and Apes, because their temporall muscles bee very small, and the substance of their eares is immoueable: but in other creatures sayth he, whose temporall muscles and eares are very large, these nerues also are large, because of the strength required to those motions. The vse of them in men is to bring Sense to the eares

The arteries of the eare.

The nerues.

eares and sometimes to moue the muscles, for those muscles are not alwayes found.

CHAP. XIII.

Of the Muscles of the outward Eare.

Ens Eares are for the most part immoueable, yet they may be moued, as appeareth as wel by their muscles as also by the nerues which as we said euen now, are found in some bodies. But the muscles are so small and the nerues so threddy that their motion is hardly perceiued: and Nature made them small because too much motion would haue vitiated the hearing, & therfore the head is rather made to moue speedily on euery side toward the sound or voice, which is not so in beasts whose eares are moueable.

Such as they are *Falopius* first found them out, and therefore the honour of their Invention belongeth to him. They are of two sorts, Common and Proper.

The first is common to the Eare and both the Lips, and is a portion of that muscle which is accounted the first of those which moue the cheeks and the skin of the face, and is called *Quadratus* [tab. 7. fig. 1. L] The square muscle; it is inserted with ascending fibres into the roote of the eare. [tab. 6. fig. 1. O]

The second is a proper muscle [tab. 7. fig. 1. neare B, tab. 4. B B, fig. 2. A] seated in the fore-part vpon the temporall muscle, and ariseth from the vpper end of the muscle of the forehead, and is inserted into the vpper part of the eare.

Table 7. Figure 1. Sheweth the muscles of the Fore-head, the Eye-lids, and the Cheeks.

Figure 2. sheweth the muscles of the Nose, Lips, the lower Iaw and of the bone Hyois.

TABVLA VII.

α A 2, the originall of the grinding muscle from the yoke-bone.

μ 2, the insertion of this muscle into the lower iaw. γ 2, A small nerue running to the forehead out of the orbe of the cies.

π 2, A nerue propagated to the face. ρ σ 2, two beginnings of the seauenth muscle of the head. T 2, His insertion into the *Mammillary* proceffe.

υ 2, the clauicle or the collar-bone. φ 2, A place where the vessels attayning to the head and the nerues of the arme do passe through.

The

The third [*tab. 7. fig. 1. neare O*] ariseth from the nowle above the *Mammillary* proceffe, where the muscles that moue the head and the shoulderblade do end, & is implanted on the backside of the eare.

The fourth proceedeth from the same *Mammillary* proceffe vnder the ligament of the gristle of the eare, and is inserted into the whole roote of the eares gristle. [*tab. 4. fig. 2. H.*] One part of it above, another part in the middest, and the third below. The more exact description of these muscles we referre vnto the Booke of muscles.

CHAP. XIV.

Of the Gristle of the Eare.

H He substance of the outward Eare is neither bony nor fleshy [*the interior face of the Eare slayed is exhibited in the first Fig. of the sixth Tab.*] but of a middle nature betwixt both, for if it had bene bony it must haue bene of a thin bone or a thicke. If it had bene made of a thin bone, saith *Aristotle* in the 9. Chap. of his second Book *de part. Animal.* then would it easily haue bene broken. If it had bene made of a thicke and solide bone, it

would

would haue beene a burthen to the head, and beside would not haue yeelded to outward occurrents. Againe, if it had beene as soft as flesh it would haue fallen into it selfe and haue been vnterly vnfit to haue made those cavitie, protuberations, furrows and such like which in the eare are very necessary: neither would it haue receiued the sound which must be returned from a hard body, and so the ingresse of the ayre would haue bene hindered.

Why moderately soft.

It was made therefore of a substance moderately soft and moderately hard, that by reason of the softnesse it might be bent on euery side and giue way to the opposition of whatsoever doeth light against it, that so it might not bee subiect to contusion nor breaking. Againe, the moderate hardnesse thereof makes it fitter to be stretched, to stand vpright, to be alwayes open, that the ayre together with the sound might euermore gather into it; for saith *Cicero* in his second Book *de natura Deorum*, when we are asleepe we haue need of this sense that we might be awaked. Moreouer, the hardnes makes it fit to receiue the cavitie and furrowes which are therein, whereby the sounds are retayned that they passe not the hole of hearing. Yea whilest the sound runneth through those cavitie, *Aristotle* saith, it gathereth strength, and by the refraction is after a sort modulated or tuned, and so cometh more welcome to the tympane.

Why moderately hard.

Finally, because it is moderately hard it yeeldeth also a sound and so the voyce or noyse is better receiued, and as it were formed without any eccho or singing, or other noyse like the fall of waters which happeneth to those *Scythians* of whome wee made mention euen now, who when their eares rotted off doe apply hollow shelles of Scallops or such like behind the holes of their eares.

The originall of the cartilage.

Wherefore it consisteth of one gristle [*tab. 4, fig. 1.*] and that flexible, couered ouer with a thin skin which cleauerth close vnto it. This gristle proceedeth as it were out of the temples and standeth aloofe from them more or lesse. For the first originall of this grytle is from the orbe [*tab. 3, lib. 7, fig. 9. y*] of the hole of hearing which is boared in the temple bone and exasperated or made rough in the circumference that the gristle might better arise therefrom. At the very originall it is thicker and harder; thicke that the roote thereof might be more firme, and harder because of the neighbourhood of the temple bone from whence it proceedeth; and by how much it standeth further off from the bone of the head by somuch it becometh the softer and the thinner.

The ligament

This gristle is also tyed to the stony bone by a strong ligament [*tab. 8, fig. 2. C C C*] which ariseth with many propagations from the *Pericra*. where it tendeth toward the mammillary processe. These propagations when they haue attained to the eare, doe all ioyne into one ligament, which is inserted into the vpper and gibbous part of the eare, to suspend or hang the gristle streight vpward. This gristle is opposed or set against the hole of hearing that the passage thereof might be larger and more extended into the hollownesse of the gristle, by which meanes the sound is as it were scouped or swallowed vp.

CHAP. XV.

Of the inward Eare.

The parts of the inward eare.

THe inward Eare hath many parts, five holes or passages, three small dennes, small bones as many; the Membrane or head of the drumme called *Typanum*; two Muskles; a Nerue from the fourth and fifth coniugation: a veine and artery and the Inbred Ayre. All which are containd in one called *Os petrosum*, or the stony bone, whose description we will here prosecute at large, because of the bones of hearing therein contained, and make but slender mention thereof in our booke of Bones.

The rockie or stony bone.

This stony bone so called, saith *Vesalius*, because it is like a rugged rocke, [*table 3, lib. 7, fig. 9. f. 2*] is the third and interior processe of the temple bone running along obliquely forward from the hole of the eare, betwixt the Mammillary processe and the processe of the yoke bone, and buncheth out in the inner basis of the skull, [*tab. 9, fig. 2. from a P toward C, & beyond*] betwixt the wedge bone & the nowle bone, so that it is much more conspicuous in the inside of the scull then it is on the outside. This processe is some-what round, the better to containe a greater quantity of inbred aire: long also, somewhat like the ridge of a rocke, and that because the nerue of hearing (which is the softest of all nerues except the Opticks) might run his long course from the braine without danger of beaking.

Where

Tab. 10. sheweth the eares and the diuers internal parts thereof.

Figure 1. sheweth the whole external eare, with a part of the Temple bone.

 C, The bone of hearing likened to a hammer. D, the auditory Nerue. G, His distribution through the great hole of hearing.
 E, A branch of this nerue going through a darke hole vnto the Temples. F, Another branch falling through the ring.
 H, A round cavity, in the fore-part whereof is placed, the bone noted with I. hole whereby a veine doth enter in. HI, A round cavity, in the fore-part whereof is placed, the bone noted with I. hole whereby a veine doth enter in.
 Fig. 6. aa, the first hole of the Organe of hearing. β, the auditory Nerue diuided into two parts, where it passeth through the fourth hole. γ, The iugular veine with a part of a nerue passing through the third hole, and a nerue falling through the same hole.
 H, the same artery falling through the fift hole. ii, the lower part of the fift Nerue reaching vnto the 2, and 3. cavity. θθ, A higher part of the fift Nerue brought through the scruiug canale or pipe vnto i, where it falleth out. u, the Tympane or Drumme shutting the first cavity. x, the three little bones of hearing ioyned together. u, the third cavity or the Trumpet of the organ of hearing. V, the second cavity or the mettall mine running out with three burroughs. ξω, the Canale or water course carrying a Nerue and an artery, opening it selfe with two holes. Fig. 7, and 8. ς, The Hammer. σ, the Anuile. τ, the Stirrop.

Wherefore the production of this bone is inward to receive the nerve as soone as it yssueth out of the *Cerebellum* or After-braine. Another reason why this production is lengthned, is because it might make a fit channell or furrow wherein to carry a branch of the *Jugular* veine or sleepey artery to the braine.]

But there where it yssueth out of the Temple-bone it is broader and thicker, that those turnings and cavities which were necessary for the Sense of Hearing might bee better insculped or wrought therein; yet as it proceedeth forward it endeth by degrees into a sharp Cone or point where the veine or artery entreth into the braine, and so the whole processe is like a *Pyramis* or spire. [tab. 9. fig. 3. o.]

The names of it.

How it is found in children.

The parts of it
The outside.

The perforations of the rocky bone.

Within the skull two.

The first.

The second.

This bone is exceeding hard for the security of the Organe of Hearing, and harder indeed than any bone of the body, whereupon it is called *Os Petrosum* or *Lapidosum*, the Rocky or Stony bone. Some use to call the temple-bones *Lapidosa*, and they call this bone *the interior processe of the stony-bone*. In Infants it is called *Os labyrinthi*, the bone of the Labyrinth, in whome it is separated from the temple bones (as also in a Calves head it will easily fall from them when it is sodden) and wanteth the halfe of that passage, which maketh *the hole of Hearing* in growne bodies. For this hole in Infants is altogether gristly and in dissections found distinct from the rocky bone: and therefore because it is without that passage we may in Infants perceive without breaking the bone, the *Timpane* as wel the membrane or head of it, as also the bony circle to which the membrane is fastened: but as the body increaseth and the gristly parts grow dry, they turne into bones even the hole of hearing it selfe; and so the rocky bone groweth very fast to the scaly part of the Temple bone vnder which it lieth, and becommeth as it were a processe thereof.

In describing this bone, we must consider his outside and his inside. His outside as it appeareth either within the scull or without the scull. The outside within the cavity of the scull is couered over with a hard and strong crust, as hard as is the substance of the teeth. The superficies thereof is smooth, not rough as it is without the scull but yet vnequall; because in the middle of the length thereof it buncheth out by reason of the *bones of Hearing* which in that place are contained; [Table 9, Figure 2, betwixt n and the lower E] so also in the vpper part there runneth a sharp and rough line through his length whereby it is diuided into two sides, and forward it endeth into a rough sharpnesse. [Table 9. Figure 2. from F toward d]

It hath many perforations that the ayre hauing receiued as it were the stampe or impression of sounds might passe through them vnto the instrument of Hearing. These perforations are of two sorts, some within the scull some without; within the scull there are two; one is a large and patent hole in the face of the processe which looketh backward, [tab. 4. lib. 7. fig. 10. a, tab. 9. fig. 2. from d to l] and this hole reacheth obliquely outward almost to the very middest of the processe: it is smooth and round in the ingresse, but dilated afterward by degrees as it were into two parts, whereinto the nerve of Hearing is implanted. This hole *Platerus* accounteth to be the sixt of the Temple bones, and the fourth hole of Hearing. But we shall account it for the seauenth hole of the Temples.

This cavity in the bones of Children is shorter, and beareth the forme of a hollowed denne or of a porch. But in growne men when the bone is increased that forme perisheth and it receiveth the figure of a fistulated hole or winding burrough; presently after the ingresse of which burrough (as may be perceiued in the scull without dissection) may be found two holes in the bottome of the entrance which goe into two bosomes or pipes, the one vpperward the other downward [tab. 9. fig. 2. e f] into which the nerve is deuided and through them conuayed. The one hole or pipe is higher and runneth more manifestly toward the vpper part of the hole of Hearing, passing obliquely outward to the inner part of the processe, and so into that canale or pipe which is called *Aqueductus* or the Water-course. [tab. 8. fig. 3. H]

It is distinguished or parted from the second and third cavities onely by a thin scale, and leadeth along the greater part of the nerve [tab. 9. fig. 2. e] of which we shall speake in the first cavity.

The other hole or pipe is lower and lesser, sometimes single sometimes double, appearing in the inside of the passage, and leading along smal furcles of the nerve into the second and third cavities. [tab. 9. fig. 2. f]

The other hole of the stony bone within the scull which *Platerus* calleth the seauenth hole of the Temples and the fift of Hearing, [table 9. figure 2. y] is in the foreside of the processe, narrow

narrow and rough like a ragged cleft through which a small artery passeth from the Organe of hearing vnto the scull : we will account this hole for the eight of the Temple bones.

The holes of the stony bone without the scull are three. The first (which we account for the first hole of the Temples runs into the hole of hearing, [tab. 3. lib. 7. fig. 9, 7, tab. 9. fig. 2. a a] which is called *σφηνοειδης meatus auditorius*. This hole, because of the gristle which is extended and stretched about the beginning thereof, hath a large and ample orifice resembling a caue or den, and it runneth betwixt the mammillary proceffe, and a part of the Jugall or yoke bone.

Without the
skull.
The hole of
hearing.

In yong children, saith *Coiter*, it is all gristly, in those that are growne it is but halfe gristly & halfe bony. The gristly part groweth out of the gristle of the eare: the bony out of the bony circle of the Temple bone. For in the first conformation it is like a bony ring distinguished from the Temple bone by a cartilage comming betweene them, from which cartilage ariseth the membrane of the Tympane or head of the drumme: and this may be perceived in the skulles of infants new borne till they be fixe or seauen months old if they bee boyled; but afterwards this gristle is dried vp and vtterly obliterated, and the bony ring or circle, of which we shall speake in the next chapter, is no more distinguished from the hole of hearing but vnited to the rest of the bone and streightned a little, making a long & round bony canal or pipe [tab. 9. fig. 2. ll] wherein to receiue a greater quantity of ayre, and also that the passage might be more patent and open vnto any sound: which canale runneth inward to the head of the drumme, [tab. 9. fig. 2. from e to c] and that obliquely vpward, or if you will describe the progresse thereof from within forth, then say, that it slopeth a little downeward, and from behind runneth something obliquely forward into the outward eare, where it becommeth somewhat more ample and large.

This passage therefore is oblique and winding to breake the vehement appulsion, or rushing in of cold ayre, that it should not dissolue the harmony of the Tympane and nerue of hearing. Againe, that a strong sound before it affect the Tympane might be communicated to the *internall ayre* and to the nerue; or be broken and so touch the membrane gently and without violence, for a slope blow offendeth lesse then that which commeth in a streight line, and yet for all this we see often times that the noyse of great Ordinance or of Bels, if a man be in the steeple, yea an intollerable cold ayer doe affect the Eare with paine and dolour; sometimes also breake the Tympane from whence deafnesse followeth.

The forme of
the hole of
hearing.

This passage also runneth obliquely from behind forward and vpward, lest those things that fall outwardly vpon the eare should easily bee admitted into the cavity, as also if any thing haue by chance insinuated it selfe that it might with greater facility fall forth againe. It is by degrees streightned or becommeth narrow; first that the ayer being beaten might be gathered into a narrow compasse, by which our hearing is farre more distinct. Againe, that if any small creatures should get into the entrance of the cavity, yet the streightnesse thereof in the bottome might stay their course or returne them backe againe.

The like also we may say of crummes, of pease, or of any such thing that should happen to fall into the eare. There is also in this place a bilious viscid and bitter humor wherewith, saith *Cicero* in second Booke *de natura Deorum*, as with lime such creatures are intangled. Wherefore also there are haire growing in those particles of the eare which before we called *Tragus* and *Antitragus* resembling the beard of a Goate.

This hole also is solide and hard, for by that meanes the sound in the passage beeing stronger beaten against the bony or hard sides of the passage is so much the more intended then if it had bene more membranous or soft. It is also inuested or couered with skin, partly to breake the sound which would haue bene more vehement if it had beaten against a naked bone: partly also lest the bone should haue bene corrupted or tainted by the ayer: wherefore it is hard, thicke, polished and strongly ioyned to the bone.

The substance
of it.

Finally, this passage in the beginning and the end hath certaine circles, the outward of which is rough, [tab. 9. fig. 2. b] because of the gristle of the eare which groweth thereto: to the inner circle the small membrane of the Tympane or the drumme-head is stretched and tyed. [tab. 9. fig. 2. c]

The primarie vse of this hole or passage is, that the ayer altered by the sound, might through it be deriued vnto the eare, and so through the concauity thereof might insinuate it selfe from the backpart obliquely foreward to the membrane of the Tympane; for through narrow, concauous, smooth and hard passages, sounds are commonly carryed, not onely with more ease, but also do more exquisitely represent the nature of the sound. And

The vse of it.

this

this shall he easily perceiue that will strike a trunke very gently at one end, so that hee that standeth by him may not heare it; and yet if a man lay his eare to the backe end of the trunk he shall easily heare how often the fore end is striken; because in the trunk as in a narrow place the ayre is condensed and by that meanes the sound vnited and sharpned; whereas if the ayre that is beaten by the sounding body shall passe thorough a large place, it will bee diffused and dissipated and loose much of his strength.

The second.

The secondary vse of this hole of hearing is for the expurgation of the chollericke excrement of the braine, (for phlegme is rarely purged this way because of his thicknesse) which through the veines attaineth to the membrane of the Tympane & through it sweateth into the hole of Hearing. In this hole also we finde a muscle of which we shal speake after ward.

Another perforation.

There is another hole which we account to be the third hole of the Temple-bone [table 3. lib. 7. fig. 9. V] scituated neare the first hole of the wedge-bone, and is a great deale narrower then the former. It is oblique, short and double, and admitteth a branch of the Angular veine; emitteth also or sendeth out a small branch of the nerue of Hearing.

CHAP. XVI.

Of the Canale out of the Eare into the mouth.

He third outward hole of the Stony-bone which we account for the fift hole of the Temple-bone [tab. 3. lib. 7. fig. 9. s] is scituated betwixt the Mammillary proceffe and the appendixe called *Styloides*, and endeth into a hole or canale which passeth from the eare into the mouth. Of this passage *Aristotle* made mention, but *Eustachius* was the first that described it, and after him *Volcherus Coiter*. This hole or passage is like a round pipe or small quill, larger in the beginning and passeth obliquely to the inward and foreside of the Basis of the braine, and in the midst of foure holes it penetrateth the whole bone where it is encreased by a substance that is partly gristly and partly membranous. But before we prosecute this passage further, we will shew you those foure holes in the midst of which this passage thorough the bone is.

where it perforateth the bone.

The first therefore is on the backside where the sleepey artery entreteth into the skull. The second is on the foreside through which the fourth coniugation of nerues yssueth out of the skull. The third at the outside making way for the artery which is to be distributed into the *Dura meninx*. The fourth at the inside is a fissure made of the extremities of the wedge and stony bones, passing obliquely downeward and forward. And in the very midst of these perforations doth this cavity pierce through the bone.

The substance of it.

Now to return vnto the substance. We said before that it was partly gristly, partly membranous. For at the last of the 4. holes or the fissure which is common to the wedge and the Temple bones the substance of it is gristly and very thick. But on the opposite part it is not exactly gristly but as it were membranous & becommeth thinner. This canale thus encreased with substance of another kind passeth between two muscles of the throate as the forenamed fissure passeth and neare the root of those proceffes which we likned to Bats wings, on the inside, I say, of them it determineth into one of the cavities of the nostrils, and is inserted into the thicke coate of the Palat neare the roote of the *Vuula*. But the inward extremity or end of this passage where it respecteth the middle cavity of the nostrils becommeth a strong gristle bunching or swelling much outward, which is couered with the mucous or slimy coate of the nose, and ser as a Porter to keep the end or outlet of the passage.

The figure of it.

The figure of it is not round but a little depressed making 2. angles, the hollownes thereof is much about the proportion of a goose quill, yet so that it is twice as broad in the end as it is in the beginning, and is likewise couered with a mucous coate, but that thin.

Why gristly.

It was made gristly that the way might be alwayes open and that it should not hurt the neighbour parts with his hardnesse, but easily yeeld without danger of breaking. Moreover, it was couered with a mucous or slimy coate, which *Laurentius* compareth to a value such as groweth within the veines as we shall vnderstand hereafter: the vse of which coate is to couer the orifice of this passage within the mouth, that euill vapours might not exhale out of the mouth into the eares. The termination of this passage is on both sides common to the nosethrilles, the pallate and the canale it selfe, that by this meanes the mouth might be a fit receptacle for all the kindes of excrements of the braine; and (which sheweth the wonderful prouidence and wisdom of Nature or rather of the God thereof) the

Where it determines in the mouth.

the very end of it is where the muscle of the chops is situate, that so when vpon our swallowing the chops are dilated or opened by the muscle, this passage also is recluded or opened to giue way to the descending excrement.

The chiefe vse therefore of this passage is for expurgation, to leade along the superfluities that fall from the head, by the eare into the mouth, as also to purge and depurate that ayre which is implanted in the instrument of hearing; for it was necessary that many excrements should in this place be gathered together, because the braine lyeth about it which yeeldeth much excrement: and we may well conceiue that many of those excrements are gathered together about the eare, by the quantity that issueth sometimes outward through the hole of hearing.

The chiefe vse of it.

An honest man of good credit told mee that hee had beene deafe three or foure yeres, at length his eare was cleansed by one that professed some skill in curing deafnesse, and that in two dayes he drew out of his eare the quantity of two great Wall-nut shels full of wax, and that therupon hee instantly recouered his hearing againe. If therefore there were so many thin excrements which could sweate through the fast membrane of the tympane, what a multitude shall wee imagine may lurke within, which for their thicknesse cannot possiblie sweate through?

A Rorie.

Aquapendens also testifieth, that hee had often obserued these inward cavities especially in children to be full of a thicke humor, slimy and mucous, which ought to haue beene purged away by this canale or passage: otherwise if it stay within, either it altogether stoppeth vp the eare, or else being resolved by inward heat is converted into wind, from whence come those singing noises and murmurs of the eares, and consequently the deprauation or vtter amission and losse of hearing.

Hence therefore we may obserue, that in inward offences of the eares, it is a very reasonable course for the Physician to prescribe *Masticatories*, because the wayes are open, eyther for Nature to expell being prouoked, or for the Medicine to draw euen crasse and thicke matter by this waie into the mouth. Beside by this meanes the passage shall bee kept drie and the drier it is the more fit to receiue sounds. And hence it is, that *Hippocrates* in the seventeenth Aphorisme of the third Section saith, that the North winde because it is dry makes a man heare the better, and on the contrary, the South winde which is moyst, duls and offends the eare.

The vse of Masticatories in deafnesse.

Another vse of this Canale is for the behoofe of the *Inbred aire* of the eare: first, to purge it and make it clearer, drier & thinner: againe to restore it and refresh it, for it is not to be doubted but that new aire is supplied out of the mouth by this passage. For considering that the *Ingenit aire* is perpetually wasted by the inbred heate, it is agreeable to the wisdom of Nature that it should be supplied by a regeneration of new aire which must be made of externall aire, because the ingenite aire was at the first made of externall. Furthermore, that the aire doth passe out of the mouth into the eares, we are taught both by *Aristotle* in the eleuenth Chapter of the first Booke of his History of Creatures, and also by experience, because when a man yawne wide he cannot heare what is spoken, and beside he perceiueth a noyse in his eares. In like manner, when a man blowes his nose or with any force containes his breath, he shall euer perceiue that the aire entereth into his eares, and with a certaine perturbation whereby the implanted ayre is disturbed, because it is a drift not without some violence or constraint; but when the ayre insinuateth it selfe of it owne accord for the refection of that which is bredde in the eare, then is the motion gentle so that wee doe not perceiue it. And beside the length of the passage prepareth and fitteth the newe ayre for the refection and nourishment of the old. Wee may also imagine that by reason of this passage, *Alcmeon* of whome *Aristotle* maketh mention in the place aboue quored, did thinke that Goates drew their breath not onely by their mouths and by their Nofethrils, but also by their eares, which wee haue no great Reason to thinke strange, because wee see that cunning Tobacconists (a generation of new and addle Artistes) can driue the smoake out of their mouthes thorough their eares.

The 2. vse of the Canales.

A third vse of this canale is, that if it happen the sound cannot directly passe vnto the Nerue of Hearing by the hole of the eare, that then at least some of it might this waie through the mouth bee conueyed vnto the organ of Hearing, and so those that are deafe dy outward accident might receiue the sound or voyce by the mouths. And this wee may verie well discerne by the receipt of the sound or a Muscical Instrument. For if a man stoppe both his eares verie close and hold a wand in his mouth, the other end whereof doth touch

The third vse.

How a deafe man may bee made to hear.

any instrument that is plaid vpon, hee that so holdeth the wand in his mouth shall bee able to discern the Musicke. In like manner if in the night time you be desirous to know whether any man be comming toward you, set a staffe vpon the ground or but a sword, and hold the end or pommel betwixt your teeth, and you shall heare a great way further off then your outward eare will be able to discern especially if the way be stony.

The fourth
Use.

A fourth use of this canale is, that in a vehement and violent noyse such as the shooting of ordnance, thunder and such like is, the membrane of the tympane or head of the drum might be secured from breaking, for surely it would bee in great danger to breake if the *Inbred aire* had no passage out. For when this Inbred aire is moued if it could not retire backward, it must passe the membrane outward toward the eare, & the outward aire we know forceth it inward by which two contrary inforcements it could not but be endangered, whereas now the inbred aire hauing an out-let into which it may retire, it leaue the membrane scope and roome to yeld to the impulsion of the outward ayre.

How this pas-
sage is found
in a skull.

He that would find this passage must take a dried skull and put a hogs bristle into the hole of hearing, and he shall perceiue that it will issue out again in the palat of the mouth. But in a greene head the holes of this canale are very conspicuous in the same palate. And thus much of the canale which runneth from the eare vnto the mouth, as also of the externall part of the stony bone within the skull with the proceffe and holes that belong vnto it.

Of the super-
ficies of this
bone without
the skull.

The other part of the exterior superficies of this stony proceffe or rocky bone without the skull is diuersly exasperated and made vnequall with knubes, bosses or cauities, porosities or smal holes and lines running in it. So that the ancients did rightly compare it to a craggy rock. The use of which inequalities is, that from them the muskles might better arise and into them be better inserted.

The mammil-
lary proceffes
of the stony
bone.

This bone also hath belonging vnto it a proceffe and an Appendix. The proceffe is some-
what thicke, and because it resemblerh the teats of a womans dug it is called *μαστοειδης mammil-*
laris. [tab. 3, lib. 7, fig. 8, M, fig. 9, K] This proceffe is not found in infants, but ariseth afterward.

Of the appen-
dix Styloides.

The appendix is slender, long and sharpe, and therefore called *στυλοειδης*. *Coster* calleth it *Os sa-*
gittale, os clauale, os acuale; from the resemblance it hath with an arrow, with a nayle, or with a
needle. It is also called *στυλοειδης*, because it is like a spur. [tab. 3, lib. 7, fig. 9, i] This Appendix
in infants new borne is gristly, but afterward becommeth bony when the bones grow and the
gristles are dried, yet for the most part as it is in other appendices there remaineth in it some
remembrance of a gristle. But of these wee shall speake more at large in our discourse of the
bones of the head. In the meane time thus much shall suffice to haue said concerning the ex-
ternall superficies of this stony proceffe of the Temple bones or of the rocky bone whether
you will, as well within the skull as without.

The inside of
the stony bone

On the inside this stony bone is not solide, the reason was, that it should not be too heauy,
but thrilled and perforated with infinite holes, dens and serued passages, [tab. 18, lib. 7, fig. 2,
4, 5, 3, 2, m n E i] and in a word the greatest part of it is a very sponge wherein the implanted
or inbred ayre is laboured or perfected. But in the midst of it there are three notable caui-
ties formed, especially to help our hearing; the small partitions of which cauities, although
they bee very thin because the bone should be light, yet are they very fast and strong bones.

Three cauities

But because the membrane of the Tympane or head of the drum is interposed betwixt the
hole of hearing and the first of these cauities, we will intreat of the Tympane before we come
vnto the cauity.

CHAP. XVII.

Of the Membrane of the Tympane or head of the Drumme.

The names of
the membrane
of the Tyme-
pane.

He Membrane of the Tympane which *Hippocrates* first of all men, in his Booke
de carnibus, made mention of vnder the name of *δέρμα τῆς τῆς ἀκοῆς*, that is, a skinne
in the hole of hearing, is called by *Aristotle* in the 83. text of his second Booke *de*
anima *μῆνις*. *Galen* in the first chapter of his eight Booke *de usu partium*, calleth
it *στυλοειδης*, a lid, and *στυλοειδης*, a covering. Some call it *Tympanum*, because it is
stretched ouer the first cauity as a peece of Vellam ouer the head of a Drumme, or because as
a Drumme being beaten with a sticke maketh a great sound, so this membrane being beaten
vpon by the ayre, communicateth this sound vnto the nerue of sense. But it may most pro-
perly

perly be called not the Tympane or drumme, but the membrane or head of the drumme, because it is stretched vpon the bony circle we shall speake of afterward, and receiuing the impression of the sound returneth the same againe vnto the sense. [tab. 10, fig. 3, and 4, p. tab. 11, d] It is scituated betwixt the hole of the hearing, at whose inward end it is set, and the first cavity of the inside of the stony bone, which cavity we properly call *Tympanum*. It is extended ouer the cavity obliquely forward and vpward, as if a man should couer the sloping cut of a writing pen with a filme: and the reason of this scituation is, because it might more directly respect the first cavity which is somewhat higher then the hole of the hearing. Again, that the violence of the aire, of water or of any such like that might by accident fall into the eare, should not directly or by a right line attaine vnto the membrane to offer it violence.

Scituation.

The reason thereof.

The second reason.

The figure of it.

The figure of it is round [tab. 10, fig. 6, & 7, tab. 11, d] curued a little inward in the midst like that herbe which wee call *Pennigrasse* or *Venus nauell*, the better to receiue the sound which commeth from without, because that which is concaveous or hollow doth more perfectly, and fully receiue the sound.

Concerning the substance and originall of this membrane, there are almost as manie opinions as there be writers. Some think it ariseth from the braine, some from the *Dura Meninx*, some from the *Periostium*, some from the *Pericranium*, some from the nerves of the first coniugation, some from the *Pia mater*. But if it may be lawful for vs to interpose our opinion, we perswade our selues, saith *Bauhine*, that it ariseth from the seede it selfe, as being generated in the first conformation as we said before the membrane of the cristalline humor was generated; and the reason that perswadeth vs thereto, is, because the very substance of it differs from the substance of the others membranes in the Body. But if this opinion should not please, we next of al incline to them who produce it from the *Periostium* because if you dissect the head of an infant, you shall finde this membrane to cleave to the *Periostium* [tab. 11, k k] where it couereth the scaly bone and the neighbour parts: as also that at the hole of hearing the *Periostium* is dilated, where there breaketh or riseth out of the stony bone a little oblique and round proceffe much like a quill when the first oblique incision is made in it toward the framing of a pen, which proceffe was ordained that this membrane might be connected with the stony bone.

Diuers opinions concerning his originall.

This proceffe is called the ring of the bony circle [tab. 10, fig. 3, & 4, tab. 11, e] out of whose circumference the hole of hearing beginneth. This proceffe hath a double originall [table 11, p] the lower groweth out of the scaly bone and resembleth a knub or knot, which bending a little obliquely inward is placed before the doore or entrance of the first cavity, where on the inside it hath a round furrow, or is lightly excavated in the middle round about the circumference with two bony brims or edges swelling out on eyther side, in which furrow the membrane groweth very fast round about, that it might be secured from the violent motions eyther of the externall Ayre entring in, or the internall Ayre beating outward, as it happeneth in oscitations or yawnings when we hold our breath long, or when we blow our Noses.

The bony ring.

Wherefore it is most like that circle in a Drumme to which the Vellum is fastned. [table 10, fig. 3, and 4, q, tab. 11, d] And this bony ring in infants is easily separated from the Temple bone, but in growne bodies it is so close ioyned on one side to the stony bone, on the other side to the hole of Hearing, that a man would not thinke it had beene ever separated from them: neyther indeed can it be separated in growne bodies without breaking. Yet the furrow remaineth still to be seene. And thus the membrane of the Tympane seemeth to be separated in the circumference from the *Pericranium*. But let vs heare what *Galen* can say of this membrane.

Galen inquiring into the substance of this membrane, and instituting a comparison betwixt the covering or coate of the Opticke and the first Nerue of hearing, and afterward of the instrument of smelling, sheweth; That it was not fit these Nerves should be left naked, because then they would haue beene exposed to all outward iniuries. Seeing then they needed a covering, either it must be crasse and thight as that of the eye; or rare and porous, or in a meane betwixt both. It behooued not it should be crasse and thight, because such a covering would haue hindered the accessse of the Ayre when it was mooued, especially if the motion were but easie, as it is when we speake ordinarily one to another. Neyther ought it to haue beene rare and porous, for then the Ayre would haue pierced through it, and so the Nerves should easily haue beene offended and the Braine it selfe refrigerated.

A passage out of Galen, proving that hee knew this membrane.

Wherefore Nature framed a Muniment or defence, to helpe the security of the Instrument, of a moderate

E, His distribution through the great hole of hearing. F, Another branch falling through the hole whereby a veine doth enter in. H I, A round cavity, in the fore-part whereof is placed, the bone noted with I. Fig. 6. aa, the first hole of the Organe of hearing. β, the auditory Nerue diuided into two parts, where it passeth through the fourth hole. γ, The ingular veine with a part of a nerue passing through the first cavity. δ, Where it passeth through his second hole neere to δ. ε ε, An artery entring that cavity thorough the third hole, and a nerue falling through the same hole. H, the same artery falling through the fifth hole. ii, the lower part of the fifth Nerue reaching vnto the 2, and 3: cavity. θ θ, A higher part of the fifth Nerue brought through the scruiing canale or pipe vnto s, where it falleth out. x, the Tympane or Drumme shutting the first cavity. λ, the three little bones of hearing ioyned together. μ, the third cavity or the Trumpet of the organ of hearing. ν, the second cavity or the mettall mine running out with three burroughs. ξ α, the Canale or water course carrying a Nerue and an artery, opening it selfe with two holes. Fig. 7, and 8. s, The Hammer. σ, the Anuile. τ, the Stirrop.

moderate consistence. And thus he concludeth: Nature therefore foreseeing that if shee had made the construction of that Nerue with a strong Muniment, it would indeede haue beene fitte to beare off offences: but the Instrument of the Sense must of necessity haue beene Deafe. Againe, if the construction of the Nerue had had no defence, it would haue beene very subiect to outward iniuries: and therefore shee tooke a way betwixt them both, and made for the construction of this nerue a helpe, neither too stiffe to hinder the sence of Hearing: nor too rare, that the aire should penetrate through it, but of a moderate consistence, which might not only secure the Instrument from violence, but also receiue & returne the impressions of sounds.

Againe the same Galen writing of the couering of the Instrument of Smelling, saith, that it needed styaqua a Defence more rare then that of the Instrument of Hearing which is fast and thight, because the object of the Sense of smelling is thicker then the object of the sense of Hearing: for the object of smelling is a vaporous substance wherein the odour doeth exhale, but the object of hearing is aire altered only by an impression of Sounds.

By this we may see that Galen was not vtterly ignorant of this membrane, and we haue the rather inserted this passage out of him, because many late Anatomists haue auouched that Galen made no mention thereof at all, but was vtterly ignorant of it. We returne now vnto the membrane.

The substance therfore of this membrane is thin, fast, dry, transluide and of exquisite sence: so thin and fine that Hippocrates compares it to a Spiders webbe, the better to transmit an easy voyce or soft sound (for it was necessary vnto the act of hearing, or if you wil, vnto the passion of Hearing, that the sound should be communicated with the Inbred ayre although the substances of the outward & inward aires are not mingled) & yet so strong withall that it might be able to beare a pulsation which might affect the instrument of Hearing.

The substance of the membrane.

Wherefore Bony it behoued not to be, for then the instrument of sense would haue been deafe, because the inbred aire would not haue receiued the sound and alteration of the external aire, and if the bone had beene so thin that it could haue transmitted the affection of the aire, then also would it haue bin in danger of breaking.

Why not bony.

It was not fit this couering or instrument should be fleshy, because if that which receiued the sound had beene lax or loose it would not so well haue transmitted the impression, for we see that the straiter a drumme is braced the stronger and louder sound it yeelds. Againe, if it had beene fleshy it would haue bin soft and full of moysture, and by that meanes would haue admitted of many things to cleaue or sticke vnto it which now doe fall away from it, because it is membranous.

Why not fleshy.

This partition therfore or muniment, or couering, call it what you will, is membranous and thin withal: for if in the first conformation it be produced a thick & fast membrane, then is the party deafe incurably, as Arantius and Laurentius haue well remembered.

But we find sometimes before this membrane on the outside that there groweth a certain thicke coate beside the intent of Nature, of which Aegineta maketh mention in the 23. chap. of his 2. Book, and Aquapendens saith he foud it twice, but Aegineta teacheth also the way how to cure it, yet it is much to be doubted that if it grow from the natiuity such children will become deafe and dumbe; Deafe because this coate hindreth the appulsion of the sound vnto the membrane; Dumbe because they are not able either to conceiue with their minds or to vtter with their voices, that they are altogether ignorant of.

How children become deafe and dumbe.

And as such a coate or filme before the membrane doth cause deafnesse, so it sometime happeneth that immediatly behinde the membrane there is a collection of mucous matter, or an affluence of some humor from whence proceedeth a great difficulty of hearing hard to be cured: but if the humor be thin then the Hearing is not so much impeached as the patient is vexed with ringings, singings, whistlings and hissing murmures in his eares. Furthermore this membrane is thight and fast, hauing in it no conspicuous pores but neruous and strong, the better to resist outward iniuries and violent incursions of the aire.

It is also very dry that it might more readily receiue the sound, and more distinctly make representation of the same. For we imagine that the Image of the Sound is receiued in this membrane without the matter, euen as the images of colours are receiued in the horny membrane of the eye. Beside Hippocrates saith that drynesse is a great helpe to the conception or reception of sounds, because that which sounderth shrillest is farthest hard, as we haue experience in small bells which are made of thin and fast Lattin plate.

Why the membrane is dry.

This membrane is also transluide and polished like a Looking-glasse both within and without, sauing that on the inside the proceffe of the bone cald the mallet or hammer is extended

The diuers
vses of the
membrane.

vpward vnto the middest thereof, like as we see in the taile of a drum there is a chord stretched ouerthwart through the midst.

The vse of this membrane is to close vp the hole of Hearing in a round compasse, and like a hedge or wall to distinguish it from the fourth cauity of the stony bone, and therefore *Laurentius* calleth it *septum*, the partition. It serueth also to distinguish the externall from the internal parts of the eare; but especially to separate the Inbred ayre, whose duty it is to receiue the impressions of sounds from the externall or the ayre that cometh from without, for if these two ayres had beene mixed and confounded, the outward ayre being oftentimes foggy and thick, must needs haue made the inward ayre also more vnfit for sensation. Neither doeth it onely keep the inward ayre from permixtion with the outward but also containeth it that it should not vanish of it owne accord, or be disperfed and dissipated in vehement noyses or Sounds. Adde hereto that it keepeth out the externall ayre so that neither the cold nor heate thereof can offend the nerues of the braine. Finally it defendeth the inward parts from outward wrongs, so that if a man be ouer head & eares in the water, yet the water cannot passe beyond the membrane: In like manner it keepeth out flies and other such busie creatures, dust and whatsoeuer else should happen to fall into the hole of hearing.

But because the thinnesse of this membrane made it subiect to be violated or indangered by such outward accidents, Nature for more security hath placed on the inside thereof 3. bones a chord or string and 2. muscles whereby this membrane is made better able to endure the force of the ayre when it is beaten against it.

CHAP. XVIII.

Of the small bones of the Organe of Hearing, and of the Chord.

The finders
out of these
bones.

He three bones of the Organe of Hearing were not knowne to Anatomists till the age wherein we liue. Those two which are knowne by the names of the Anuill or the Stithy, and the Mallet or Hammer were inuented or found out by that restorer of Anatomy, *Iohannes Carpus* of Bononia, & the third *Iohannes Philippus Ingrassius* challengeth to himselfe, so doth also *Columbus* & *Enstachius*, & well it may be that all these being so oculate Anatomists did find it out by their industry. But now we haue them, it shall be more expedient precisely to describe them vnto you then to determine who were the first inuenters of them.

The situation

These bones therefore are scituated in the first cauity of the stony bone, which before we called the Tympane that is the drum or taber, and because their figure is diuers they haue also diuers names giuen them, partly from the similitude they haue with things whose names they beare, partly also from their vse. The first is called *Malleus* or *Malleolus* the Mallet or the Hammer. The second *Incus* the Anuill or the Stithy. The third *Stapes* the Stirrop [tab. 10. fig. 6, 7, 8.]

Their names.

The Mallet.

The Hammer or Mallet [tab. 10, fig. 4, r, fig. 5, c, fig. 8, q, tab. 11, c, l] is seated in the beginning of the first cauitie of the stony bone [table 10, fig. 2, neere to c] at the end of the hole of Hearing. This bone saith *Coiter* hath his name rather from his vse then from his forme, because when the membrane is mooued, the Mallet also is mooued therewithall: or because like a Hammer it lies vpon the Anuill, and in the motion beates vpon the membrane. Others doe liken it to the thigh bone, as *Vesalius* on this manner. As the thigh neere the necke thereof hath two proccesses, so this small bone hath two proportionable proccesses in the necke thereof, whereby it groweth more strongly to his membrane. Again as the necke of the thigh bending obliquely to the cauity of the hanch endeth in a round head, so this bone departing inward from the membrane and ending in a round smooth and plaine head, is ioyned to the vpper part of the other bone by the interposition of the membrane, as if a hammer were loofely tyed to a Smiths Anuill. This first bone therefore is long and crooked, hauing a head, a necke, and a taile.

His head.

The head is the vpper and thicker part, long and bunching out, for this head is not perfectly round, as hauing ingrauen in the outside of the top a small and long cauity wherein it receiue the head of the second bone which we called the Anuill, whereto being ioyned, it listeth it vpward and forward to the side of the hole of Hearing.

Necke.

The necke of it is but narrow, yet on the backside thereof do two small proccesses shoote out,

out, which are very slender and sharpe. To the vppermost adhereth the ligament or chord and the lowermost resteth vpon the membrane that it might not be driuen too far inward or broken. But the vse of this proceffe I cannot better demonstrate then by those Chords which they vse to stretch vpon the bottome of a drumme whereby it is secured from the violence of the ayre which is within it; which aire otherwise being so violently and so often beaten, would rend the bottome asunder. Betwixt these is a small cavity and right opposit against it a little knobbe into which one of the Tendons of the Muscles is implanted, as the other is into the necke.

The tayle of this bone which *Fallopian* calleth *Pediculus* as it were the *Stalke* is somewhat broad in the top, but endeth into a small knot which receiue the insertion or tendon of the muscle; (*Columbus* addeth, that into this sharpe proceffe there determineth a small Nerue from the first coniugation which affoordeth a hairy and crooked branch which is inserted into the labyrinth of the eare) presently after it runneth backward and downward, and by degrees endeth into a slender and sharpe proceffe, somewhat rough and a little incurved or hooked, so that it cleaueth to the membrane of the Tympane, not in the end or point of this proceffe but thoroughout his length, yet not in the very middest of the membranes breadth. [tab. 10, fig. 4. from r, to P]

And Tayle.

The reason of this Connexion is partly to defend the membrane from outward violence, that it should not bee driuen beyond his extent (wherein also it is assisted by the chord of which we shall heare euen now) partly to draw it downward and inward, for the proceffe wee spake of is curved or hooked inward, and by this meanes the membrane is made inward conuexe, and outward hollow, in which figure it is also by this proceffe preserved, whence it cometh to passe that the outward aire which entereth the hole of hearing slideth from the sides of the membrane and gathereth it selfe together in the center where the Mallet hangeth, and being so vnited and intended is a great furtherance for the communication of the sound to the inward parts.

Again, as this Hammer groweth to the Membrane [tab. 10, fig. 6, n] by his lower proceffe and the inferiour part of his tayle, as also to the orbe of the hole of Hearing by the benefit of a ligament which runneth ouerthwart from the prominence which is on one side the hole to the prominence on the other so that it is no where at liberty, but on euery side fastned to the membrane: in like manner the head thereof is articulated to the Anuile vpon which it lyeth by that kind of articulation or iuncture which we call *Ginglimos*. [tab. 10, fig. 6, 7, 8.] For in the Hammer and the Anuile there is a cavity and a head, and the Hammer is mooued about the Anuile. Notwithstanding this Hammer and the Anuile after a man is dead are so closely ioyned (whether it be so in liuing bodies it is much doubted) that Nature seemeth to haue as much vse of their continuity and vnyty as of their diuision and plurality: for being two they do better safeguard and defend the Membrane, but their continuation awayleth nowhit lesse for the better conueyance of the sound. Wherefore although the articulation of these two bones is worthily said to be *per Ginglymon* because they mutually receyue and are receyued one of another, yet because of their strait and close copulation some are of opinion that their iuncture is rather to bee referred to that kinde which wee call *Synarthrosis*, the meaning of which words of Art shall bee at full expounded in our last Booke of the bones.

The Connexion of the Hammer.

Finally, the Hammer is a longer bone then the Anuile but withall more slender, because it was to mooue about the Anuile, and wee know it is reasonable that that which beareth should bee greater then that which is borne. Notwithstanding both these bones in the place where they are articulated or ioyned, are much greater and thicker then in their other part, which thing to say true may be obserued almost in the articulations of all other bones of the body.

The forme of it.

The Anuile [Table 10, figure 4, f, Figure 5, 1, figure 7, and 8, b, table 11, m] is the second bone which is situated in the hinder side of the first cavity and lyeth next to the Hammer to which it is opposite, and couereth (sayth *Cotter*) that part of the Membrane which is not covered by the Hammer, yet so that his thicker part is toward the eare and his legges, (if wee may so call them) or his thinner parts toward the Tympane. Some are of opinion as *Columbus* and *Archangelus*, that this bone had his name from his action, because as an Anuile it receiue the stroke of the Hammer, which mooueth about it and beareth against it: Others conceyue that it hath the name from the similitude it hath with a Smiths Stithy or Anuile, not that great one whereon they driue sledges of Iron, but the little and moouable

The Anuile.

The reason of the name.

Why called
Dens.

moouable Anuiles which are partly plaine and partly round. And heereupon *Vesalius*, *Eustachius*, *Cotter*, *Platerus* and *Aquapendens*, (because it is not altogether plaine as a great Anuile is, but hath an vnequall cavity such as is to bee seene in the top of the *Grinding* teeth) haue likened it to a tooth hauing two fangs or rootes, the one longer and smaller, the other thicker but shorter, insomuch as they call it not *Incus* or the *Anuile*, but *Dens* the *Tooth*.

The forme of
it.

This bone is shorter and thicker then the Hammer (*Aquapendens* saith as thick againe) and hath two legs; for in the vpper extremitie it is thicker and swelling, and in a smooth cavity receiue the head of the Hammer: it hath engrauen in it a small *sinus* or bolome, which *Aquap.* calleth an *vnequall cavity*, in the midst whereof riseth a line, as it is in the bone of the *Cubite*

The articula-
tion.

where it is articulated to the Arme, so that the articulation thereof is more truly sayd to bee made by *Ginglymos*, which for the motion is more expedite and ready. And as the head of this Anuile is articulated with the Hammer, so the productions or processses thereof doe grow to the orbe of the hole of Hearing, and to the toppe of the Stirrup or third bone. For the lower end thereof which is also the smaller doth deuide it selfe into two slender and acute processses (which *Falopius* and *Laurentius* with some others doe call Legges) standing off one from another.

The processses.

The higher of these which is the shorter and the thicker, is somewhat broad, a little intorted or bent inward and leaneth vpon the Scaly bone of the Temples, and by a transuerse ligament cleaueth to the walles or sides of the orbe of the Tympane euen there where the water-course slideth, & by this meanes it is tyed more strongly to the hammer, that when the membrane hapneth to be vehemently shaken, the two bones might not be separated one from the other.

The other processse of this Anuill or roote of this Tooth is somewhat longer, slenderer and bending downward; yet sensibly intorted vward, it appeareth about the membrane and is tyed to the top of the stirrup by the mediation of a ligament and affixed thereto by that kind of coniunction which we call *Arthrodia*, occupying that place of the membrane wherein the Hammer is not, whereby it might *Perceine* or receiue the pulsion of that part, and communicate the sound to the stirrup, from whence through smal holes it is ledde along vnto the nerue of Hearing.

The Stirrup.

The Inuenters.

The stirrup [*tab. 10, fig. 4, t p, fig. 8, T, tab. 11, f*] called *Stapes*, is the third bone of the eare, which the first Inuenters did very aptly expresse by this resemblance. Many contend about the Inuention of this bone; among the rest *Columbus*, *Ingrasias*, *Falopius*, and *Eustachius*, all excellent Anatomists and haply all of them as fortunate in the finding it out as they haue bene diligent to search into the secreet corners of man; and therefore we will not determine any thing in the preiudice of any of them. We finde it to be scituated as it were in the midst of the first cavity of the stony bone neere the *Ouall window*.

The figure.

In brute beastes it is triangular, very like the greeke letter Δ [*tab. 10, fig. 8, sheweth the fig. of it in brute beastes*] but in men it may be sayd to bee formed of two parts, [*table 10, figure 7, sheweth the forme of it in men*] the one *Superior* which is bent like a bowe hauing two small Legges somewhat sinuated, which becomming narrow are inserted into a transuerse Basis.

The top.

The top thereof is not sharpe but hath a small plaine and round head, wherewith like an arch it sustaineth the longer processse of the Anuill, or if you wil the Stirrup hangeth to this processse by the mediation of a ligament.

The sides.

The sides or legs of this Stirrup are very small and depart but a little asunder, making a hole betwixt them more long then round. Some say it is Triangular, others of an Ouall forme; but the Basis of the bone (which is the part remaining) is transuerse, somewhat broad and the edge thereof a little thicker then the other part.

The basis:

The Basis also shooteth out a little beyond the legs or side-bones thereof, whereby it is articulated to the bone at the *Ouall window*, and is firmly fastned to the membrane which shutteth the perforation, and that by the helpe of a ligament arising from that side of the head which hath the cavity *Varolius* called it very elegantly $\gamma\alpha\nu\theta\epsilon\delta\iota\nu$ as it were the *Pupilla* of Hearing. And on this manner it doeth exactly represent the forme of a Stirrup, not such a Stirrup as is vsed now a dayes, but such as we see grauen and figured in old pictures and tables, that is, triangular, and representing the fashion of the greeke letter Δ .

The perforati-
on.

Why lesse then
the rest.

This bone is much lesse then either of the other two, for if it had bene bigger or waighed more, then being moued together with the other two, it would haue drawne the membrane

downe-

downward. In the middest it is perforated or open like a stirrop, that it might be the lighrer, and that hereunto the Inbred aire might insinuate it selfe and be moued. Again the better to conuay the sound which it receiueh communicated from the Anuill not only to the depth of the first cavity, but also beyond to the other cavity, and so through the *Quall window* directly vnto the Labyrinth. Wherefore without this stirrop the sound could not haue beene transported into the whole cavity.

For example, as the visible species or forme which is received within the horny coate must first passe through the narrow & streight hole of the *Pupilla* or Apple of the eye before it can arriue at the cristaline humor: so the species or forme of the sound which hath gotten into the concauity of the membrane, must passe vnto the chiefe Organe of hearing through the small hole of the stirrop bone: and thence it was that *Varolius*, as we said euen now, called this hole of the stirrop *Pupillam auditus* the Apple of the eare.

Wherefore, as wee sayd, the formes of Sounds passe through the emptie hole of the stirroppe into the cauities which are wrought by Nature in the Stony bone where they meete with the Inbred Ayre, which may also bee compared to the Christaline humor. For as the Christaline is the chiefe Instrument of the sight in respect of reception of Images or Formes; so is this In-bred ayre of the Eare the chiefe Instrument which receiueh the Formes of Sounds, although there bee another more noble Organ which iudgeth of them.

Moreover, lest these three bones if they should haue mooued inconstantly, might haue endangered the Membrane to which they are firmly tyed by drawing it too much this way or that way, it is fastened to the bone with a small ligament or chord, reaching overthwart from the sides vnto the top of the stirrop. Yea they are tyed together with slender and soft Membranes which doe the office of a Ligament, and that by two ioynts which in their extremities are cruisted ouer with a gristly substance after the same manner that it is in other bones, and so their articulation doth not differ from the Syntax or coniunction of other parts.

They were made three in number (though some creatures haue but 2. as *Casserius Placentinus* recordeth) for their better motion whereby the membrane is secured, which otherwise in violent concussions of the aire might haue beene broken. For if it had beene but one bone, the membrane in impulsioe could not haue giuen place because the bone would not haue bent therewith; or if the proceffe of the bone should haue yeilded, being necessarily so fine and thin, it might easily haue crackt a sunder. Wherefore the membrane of the Tympane is so fastened to the taile of the Hammer that it might not breake when it is violently driuen inward: And againe the taile or handle of the Hammer cleaueth vnto the membrane that it might not be driuen too much outward. But that it might better resist any violent motion outward or inward, there were two other bones added to the Hammer to helpe the flexion; and two muscles whereby the motion is restrayned when the Hammer with the membrane is driuen with violence eyther inward or outward. For the bone which wee compare to a Hammer hath a double motion, as *Arantius* elegantly obserueth, pressing forward and recoyling backward.

Forward or inward according to the motion of the membrane whereto it is annexed, which membrane being shaken by the outward ayre is driuen inward, and vpward, remaining so long gibbous on the inside till the Inbred ayre is affected with the sound, which ayre wandering through the circles, conuolutions and burroughs of the eare, maketh the representations of the Sounds to bee received by the branches or tendrils of the fift payre of Synewes, by which they are conveyed in a moment of time into the Braine. But that this membrane should not be driuen too farre inward, the Hammer opposeth it selfe. The Hammer determineth at the small cavity of the Anuill whereinto the head of the Hammer is articulated; wherefore the Anuill being a firme and stable bone, stayeth the inclination of the membrane, euen as saith *Arantius*, in clocks there are certaine points of iron which will not suffer the wheele to runne beyond the number limited for the time of the day. And as the Anuill is assistant vnto the Hammer by laying a law vpon his motion; (and therefore hath two legges or processees whereby it is fixed to the stony bone and the stirrop) so also the stirrop standing vpon the cavity of the stony bone neere the circles as it were vpon a stable basis, doth elegantly sustaine vpon his head which is built in the manner of an arch, the longer proceffe or leg of the Anuill.

The second motion of the Hammer is outward, for the Membrane of the Tympane together

Why perforated in the middest.

Varolius.

The reason of their connection.

Why more bones then one

The double motion of the hammer.

Inward.

Outward, together

gether with the Hammer when the violence or constraint which before bare them inward is remitted, do returne vnto their naturall station; partly by a naturall motion whereby they recover their former position when the violence is intermitted; partly by the muscle which is an instrument or arbitrary motion; for that muscle is contracted toward his originall and so the head of the Hammer is separated from his structure with the Anuile, and the recured pro-
 cesse of the Hammer beareth the membrane outward. But beside these two bones, the 2. mus-
 cles also of the inward eare do assist the membrane, one of them against the inward impulsio[n],
 and the other against the outward expulsion.

The substance
 of these bones.

The substance of these bones is hard, dense and smooth. Hard for that helpeth the hearing,
 as also addeth a greater strength and firmitude vnto the membrane. They are also dense and
 smooth for the better reception and transportation of the sound; yet *Columbus* and *Cotter* are
 of opinion that the two first are within spongy and medullous. The third is so smal that there
 can be no holes perceiued therein.

How they dif-
 fer from other
 bones.

And as these bones in forme and figure doe differ much from other bones of the bo-
 dy, so also and especially they haue two notable diffimilitudes or disproportions from the
 rest.

The first is that they are not compassed about with the *Periostium*, least saith *Aquapendens*
 and *Casserius Placentinus*, they should be vnfit for the reception of sounds: for if you couer
 a hard body with a soft cloth and then strike vpon it, it will not yeeld so shrill a sound as it
 doth when it is bare or naked.

Why children
 do n[ot] heare so
 well as grown
 men.

Againe, therein they differ from other bones as all Anatomistes doe concur, that they
 are perfect and accomplished at the very birth, hauing the same magnitude then that they
 haue in olde age; partly because man at all times euen from his Infancy hath great neede of
 the Sense of Hearing as well to learne to speake as to gather knowledge: partly because the
 membrane of the Tympane is as much subiect to danger by outward violence in our Infancy
 as in any time of our life. Notwithstanding they are not so hard in Infancy as in old folke,
 for Children are full of moysture: whence it is that Children doe not heare so suddencie
 as growne men, because to the exact perfection of the Sence there is required a notable dri-
 nesse.

Aquapendens addeth a third difference betwixt these bones and other bones of the body: for,
 saith he, these bones of the eare do hang suspended from a membrane. Whence it commeth to
 passe that the externall ayre together with the sound is more easily communicated by the
 Hammer and the Anuile to the ayre implanted in the eare: for Soundes are more liuely com-
 municated to hard bodies, which hang loose as you may perceiue if you tie a peece of Iron to
 a string and strike vpon it, it will yeeld a shriller sound then it will if it be not suspended. But
 this conceit of *Aquapendens* sounds but harsh in *Casserius Placentinus* his eares, though to vs it
 found reasonable.

Why they are
 hollow.

These bones are also hollow, as well to make them the lighter, as also to contayne Marrow
 for their nourishment, whereto we may adde, that that which is hollow maketh a better re-
 sonance.

Their vses.

And albeit these three bones are of all others the least in quantity, yet by that which hath
 beene said, we may conceiue that they are of great vse and necessity. In a word, their vses are
 first to establish and defend the membrane of the Tympane, least it should be torne either by
 inward windes gathered in the braine, or by the violent motion of the outward aire, as in thun-
 der, shooting off Ordinance or such like.

Secondly, they yeeld some assistance vnto the Sense of hearing, for by their help the sound
 is conuaid by a kinde of consequence or succession to the auditory Nerue. For vpon their
 commotion the chord is shaken and the implanted aire is moued to receiue the sound. Now
 the chord could not haue been so vehemently moued by the membrane alone as by the mem-
 brane and the bones; and so these bones together with the chord being shaken by the appul-
 sion of outward aire, doe conferre vnto the distinction of Sounds as the Teeth doe to the ex-
 planation of the speech.

Anatomistes
 are here at a
 losse.

I am not ignorant that many men haue busied themselves to finde out the particular vse of
 each of these bones, wherein what satisfaction they haue given themselves, I know not;
 certainly to vs that reade their writings they giue but little. Their conceits beeing meere
 speculations, and so intricate for the most part, as if they did vnderstand what they would
 haue said, yet they haue not beene able to expresse themselves vnto others. *Cotter* mee
 thinks resoluth very well that their exact history especially for the vse, is not so curiously
 to

to bee sought into, because it is impossible that wee should attaine further then a bare coniecture, and beside something would be left by vs for admiration, especially where our vncertaine guesses cannot bring vs any great profit sauing the satisfaction of an ouer curious conceit.

It remaineth that wee speake of that slender and neruous Chord which is within the membrane. It doeth not indeed compasse the membrane round about, but running thorough the midst thereof is fastned to that ioynte where the stirrop is articulated with one of the Legs of the Anuill. This Chord if it be drawn out is thrice or foure times as long as it appeareth before it be drawn. For the substance *Eustachius* taketh it to be a branch of the fourth coniugation. *Falopius* ingenuously confesseth that he knowes not what to call it, yet resolues to giue it the name of a Nerue, and with him *Coiter* consenteth. *Ingrassias* calls it a thred or a chord: *Aquapendens* a slender rope of the nature of a ligament, or, saith he, if it be not so nor any of the other aboue named, then is it a body of his owne kinde.

Howsoeuer it be framed or of whatsoeuer, the vse of it seemeth to be for pulsation, for as in a Drumme the sound is made by the repercussion of the chord which is streatched ouer the Vellum or the Skin, so in the eare saith *Coiter* this chord receiuing an impression by a beating made vpon it from the three bones, doth strike the inward ayre whereupon Sensation is made.

The Chord.

Diuers appellations.

The vse of it.

CHAP. XIX.

Of the Muscles of the inward Eare.

THe Hammer being articulated to the Anuill with that kinde of articulation which we call *Ginglymos*, it followeth that their motion must be very obscure, now they are moued together with the membrane at which the Hammer hangerh, vpperward and downward hauing one muscle appointed for this motion within the membrane, another seated without it.

The intermall muscle [*tab. 11. fig. 2. 1*] described first by *Eustachius*, and scituated in the stony bone, is exceeding small, there being in the whole body none lesser: and yet the frame thereof is so elegant as no muscle in the body may be compared thereto. It ariseth in the Basis of the wedge-bone in that place where there is a hole made with a root of the proceffe of the stony bone, and an additament of the nowle-bone.

The intermall muscle.

It taketh his originall from a substance much like a ligament. Afterward it becommeth fleshy, and groweth a little broader euen to the very midst; then it is againe angustated or straightned and produceth (*Eustachius* saith) but one Tendon. Whome *Coiter* and *Aquapendens* do follow. But *Casserius Placentinus* and according to him *Bauhine* say, they are 2. very small, [*tab. 11. fig. 5. below i*] one of which is inserted into the vpper proceffe of the Hammer, the other into the necke thereof. But in Dogs a little before the insertion it hath a fleshy and round glandule a little depressed, which is not fixed to the membrane lest if it were drawn by it selfe being very small it should be in danger of breaking.

His originall and progreffe.

This muscle when it worketh draweth the head of the Hammer obliquely forward, and inward deduceth or inclineth it from the Anuill, and bending the proceffe of the Hammer driueth the membrane outward.

That this is the vse of this muscle *Arantius* proueth by an experiment on this manner. If, saith he, in a Greene head that is well dissected till you come to this part, you draw this muscle with a sharpe hooke toward his original, you shall finde it hath a double vse: one that the head of the Hammer wil manifestly recede or depart from the Anuill and be lifted vp, the other that the membrane will be driuen outward.

The vse of it according to *Arantius*.

Now this motion which is made in the eares although it seeme to be voluntary, because it is accomplished by a muscle which is an instrument of voluntary motion; yet it can hardly be perceiued by our selues, yea we heare whether we will or no, the reason is because the muscle is so very small.

Neither do we want examples of many muscles which we know assuredly do worke as well while we sleepe as while we wake, which yet we cannot obserue in our selues, but their motion seemes to be without our consent, as we may instance in the muscles of respiration, of the eies, of the cie-lids, the bladder and the fundament. Yet in some men this motion is more eident, which

Aquapendens
his demonstra-
tion of the
motion of the
muscle.

which also they can at their pleasure moue or containe. The truth of this *Aquapendens* proueth on this manner: The motion saith he, is Sensible, and with a kind of noyse, as if a man should stretch 3. threds a little distant one from another, and strike them with a cittern quill as wee do strike an instrument; or as if a man should scratch ouerthwart the graine of a wanscoate, or imagine it to be like the noise that the Steele makes when you strike fire out of the Flint. This motion is especially perceiued when a man begins to yawne, but in the beginning of it wee heare a kind of obscure or dull sound from the comotion of the aire. But this motion or noise in the aire many men do not obserue, neither doth it seeme to me saith *Casseri*, to haue any vse or to conferre at al to the sense of hearing; for if there be a noise in the aire and at the same time a man shall strue to stirre vp this motion, he shall heare the outward noise more imperfectly. And therefore this motion seemeth to happen either from the necessity of the matter, the Muscles necessarily following the attrition of the Hammer against the Anuile, or else it was ordained by Nature for the auoyding of vapors. For in Agues wherein many vapors do arise vnto the head this noise is frequently heard, which we conceiue to be when as the vapors which fil the cavity of the eares are by this motion dislodged, and yet we may vnderstand that this motion is not altogether at our owne disposition.

Bauhine dez
monstration
thereof out of
the experience
in himselfe.

In like manner saith *Bauhine*, when the eares are purged into the mouth by the passage that way opened, I am wont to perceiue in my selfe a kind of tickling within my mouth neere the roote of the *Vuula*, at which time if I often swallow my spittle, I doe manifestly perceiue by the noise that that motion is ordinarily stirred vp in mine eares: and I perceiue likewise the foresaide tickling to bee appeased when the matter by that meanes is sooner purged into my mouth.

It is lesse in
great Beastes
then in men.

But how commeth it to passe that this motion is perceiued in both the eares at once? It may be answered, that it happeneth in the eare as it doth in the eye: for when one eye is moued, the other also instantly accompanieth it, as we haue shewed before. A man would imagine that in large bodied creatures this muscle might be better perceiued then in a man. But we find it farre otherwise; for although beasts haue it, yet for the most part it is in them lesse and harder to finde then in a man.

How to finde
this muscle.

He that is desirous to find out this muscle, must lightly cut the stony proceffe thoroughout the length, guiding his Knife by a line which runneth there through but not very high, beginning at that part of the proceffe which is next vnto the wedge bone, for the muscle runnes length-wise and so determines into the membrane of the Tympane.

The other
muscle with-
out the mem-
brano.

The other Muscle [*tab. 11, fig. 1, and whose insertion is at b*] is situated without the membrane of the Tympane in the vpper part of the hole of Hearing about the middest thereof. Concerning the inuention thereof two excellent Anatomists of Padua in Italy doe contend. For *Hieronymus Gabritius ab Aquapendente*, whome therefore we call *Aquapendens* affirmeth, that he found it in the yeere 1599. But *Iulius Casserius Placentinus* auoucheth, that he obserued it the 7. day of March, in the yeere one thousand five hundred ninety three. But out of question they both haue deserued wonderous well of this Art which of them soeuer was the first inuenter thereof.

Bauhine hono-
rable remem-
brance of *A-*
quapendens &
Placentinus.

And because, saith *Bauhine*, I would haue the world know how much I esteeme them both, I will set downe both their descriptions thereof, beginning with *Aquapendens*, because hee is the Ancienter, not to derogate from the other, seeing I loue and honor them both. The one was my maister in the yeeres one thousand five hundred seuentie seuen, 1578. and 1579. the other in the yeere 1579. was my friend and fellow-Student, and this friendship to this day we maintaine by entercourse of Letters, and shall do I doubt not so long as we liue. *Aquapendens* therefore hath it thus.

Aquapendens
his description
of this muscle.

Furthermore this yeere 1599. I found a muscle in the hole of hearing, cald words *anastinos* [*tab. 10, fig. 9*] which is without the membrane very small, fleshy and not without a tendon which proceedeth directly from the midst of that hole or passage, till it be inserted into the very center almost of the membrane on the outside iust against the place where the hammer on the inside is fastned to the membrane, which together with the Hammer it draweth outward. You shall finde this new muscle if in a Greene head you cut the vtter shell of the bone which maketh the Hole of hearing on both sides, which you may best do with a Chizell and a Mallet, and so remoue the bone carefully to the sides, for so the Muscle will appeare, and yet I haue not bene able to finde it in all my latter dissections, although I esteeme the necessity of it to be so great that I thinke it was rather the fault of my diligence then a defect in Nature. Thus farre *Aquapendens*.

Casseri *Placentinus* describeth it on this manner.

In a man there is another Muscle situated in the vpper part of the hole of Hearing, [tab. I I. fig. 1, a b] about the middelt whereof the skin and the membrane which being implicated or folded together do inuest the said hole, do evidently degenerate for the forming of this muscle into a fleshy body: but almost membranous, distinguished or lined through with fibres, having also a Tendon. The figure of the muscle is round and in the progresse groweth slenderer by degrees, and so passeth directly on vnto the Tympane. It is inserted not into the outside of the membrane neere the center, but the tendon (which it transmitteth with a double extremity or termination into the cavity of the stony bone betwixt the Tympane and that part of the temple bone from which the bony ring proceedeth) is fastned on the inside into the head of the Hammer, betwixt the vpper and the lower processe thereof. The inuention of this muscle if I attribute to my selfe I shall not defraud any man of his due commendation, for I obserued it the seuenth of March in the yeere 1593. in the presence, &c. Thus far *Casseri* *Placentinus*.

Placentinus
description.

The vse as well of the Internall as of this externall Muscle *Aquapendens* thus expresseth.

The vse of these muscles is for the security of the membrane, for because it might haue bene broken or torne either on the inside or the out, Nature provided a strength or defence in both places. For on the outside the aire being violently moued might haue broken the membrane

Aquapendens
his opinion of
the vse of the
muscles.

by thrusting it inward, and on the inside by beating it outward; in the outside the externall ayre which with violence together with the sound rusheth into the eare, on the inside the aire which thorow the mouth getteth into the eare doth forcibly sometimes drive the membrane from within outward, and in this manner is the membrane stretched ordinarily in yawnings, blowings of the nose, retention of the breath, strong contentions, lowd voices, the excretion of excrements, and such like violent constraints. The externall muscle therefore when the membrane is driven inward draweth it back, and as it were recalleth it into the right place. In like maner, the internall muscle retracteth it inward when it is turned or driven outward. And these are the necessities for the satisfaction whereof Nature ordained these two elegant muscles, to wit, for the preservation of the membrane.

The reason why the custody of the membrane was committed to a muscle, that is to an instrument of voluntary motion, is rendred on this maner. If any other tie but that of a muscle had bene made the *Custos* or *Vindex* of this muscle, such a tie must have held it alwaies stretched or tentred alike, and so the membrane would rather have bene more endangered then any whit secured. Besides, it was very necessary that as the impulsions of the aire vnto the membrane are diuers, so there should be a variety of power in that that was to curbe or limmit those diuers motions or impulsions. Such a variety of power cannot be imagined to be in any Ligament but onely in muscles which make their operation with a certaine Analogie or proportion to the finall end which Nature intends, or according to measure; contracting and relaxing themselves more or lesse as neede shall be, accomodating their motion diuersly according to the diuers impulsions of the aire; for they suffer the membrane only so to receiue the offered violence, that neither the violence might bee altogether withstood but that the membrane might yeeld thereto, nor yet the membrane bee outraged by such violence. In a word, these muscles partly by yeelding and giuing ground, partly by obliuation or opposition do secure the membrane from being torne and rent asunder. Thus far *Aquapendens*.

Placentinus
opinion of the
use of the mus-
cles.

Placentinus thus. The muscles of the inward eare do one of them assist the Hammer against internall impulsions, the other against externall. The outward muscle which I found out, that sendeth his Tendon into the cavity of the stony bone and ioyneth it selfe with the greater proceffe of the Hammer, draweth that part of the Hammer outward which inclineth inward, and so moderateth the compression thereof made vpon the Anuile, that it is a defence against the internall muscle.

The Internall which ariseth from the wedge bone and passeth into the cavity of the stony bone vnto the Head of the Hammer into which it is inserted, succoureth the same against the former when it is driven inward, defining & limiting his introcession. For when the tympane by an irruption of outward aire, is together with the hammer driven inward, this muscle resisteth their motion that the tympane and the hammer should not be constrained beyond their Tether and so suffer laceration. Thus farre *Placentinus*.

Varolius his use
of a muscle in
the Eare.

Varolius concerning this matter (for we account him also among our classicke authors, especially concerning the head) writeth on this maner.

Although, saith he, the sound do moue the sence of Hearing whether we will or no, yet there is in vs a kind of voluntary Animaduersion which we exercise in all our senses at our owne pleasure when we would iudge curiously of any sensible thing. Wherefore as by the helpe of the muscles of the eye men do voluntary direct the center of the cristalline toward the obiect which they attentively behold, so within the organ of Hearing there is placed a smal muscle, which arising from the fore-part is inserted into the articulation of the triangle (so he calleth the *Stirrop*) with the Anuile: when this muscle is contracted, the triangle or stirrop is drawne a little forward, the ioynt of the Anuile with the Hammer yeelding thereto, and approacheth more directly to the center of the Tympane, and at that time we heare with more attention and better iudgement, like as we are able to see the least visible obiect when we stedfastly behold it by a line concentricall to the *Horny membrane*, the *Pupilla* and the *Christalline humour*. Some haue imagined that the small bones of the eares diuersly moued by this muscle, doe make within the organ of hearing many and different sorts of sounds, whose opinion we think sufficiently confuted by the former assignation which we made of the use of the muscle. Thus farre *Varolius*.

CHAP. XX.

Of the Cavities of the Stony bone.

Albeit we purpose in the Booke of Bones as particularly as we can to follow their history; yet because this Stony bone and the dissection thereof is most necessary for the understanding of the manner of the sense of Hearing: Wee haue determined to make our particular description thereof in this place; and to passe it ouer with little more then bare mention in the Book of Bones.

Why wee in-
treat of this
bone here.

Although therefore (as before is said) the stony bone is within altogether *Cavernous* and spongy, and that the Ancients haue made mention of one onely Denne or Cavity therein: yet we wil reckon vnto you 3. notable ones and of great moment, which also the *Neotericks* or later Anatomists haue called *Dennes* and *Caues*.

3. Cavities.

These Dennes or caues are formed in the middest of the stony bone where it swelleth most, to containe the Organs of Hearing, that is to say, the membrane, the three small bones, the internall muscle, the chord, the auditory nerue and the inbred aire, which also is called the internall *Medium* of this Sense. All which caues may more distinctly and distriktly be demonstrated in Children, then in growne Men. *Placentinus* findes them also very conspicuous in Birds. They haue each of them proper names borrowed from externall things: the first is called *Concha* or *Tympanum*, because it is like the shell of a winkle or a Taber. The second is called *Labyrinthus*, because of the turnings therein. And the third is called *Cochlea*, because it is like a Snail's shell.

Their names.

The first [tab. 10, fig. 2, b, from c, to E, tab. 11, q, r] cavity is layd open, when the membrane of the tympane is taken away. It is called *Concha*, as we said euen now, because it is like a winkle or Periwinkle, so acknowledged by *Aquapendens*, *Placentinus*, *Arantius* & our author *Baehne*, although I know there is great contention against *Aristotle* in this point, who seemeth first to haue giuen this name to this cavity. But we stand not vpon names so much, so we know the thing signified by the name. The better appellation as me seemeth is a Tympane, because this cavity couered with his membrane resembleth a Drum or Taber, for when the membrane is stricken by the Sound it resoundeth againe, as a Drum if it be beaten (by reason of the aire therein contained) rendreth a great sound.

The 1. cavity.

The reason of
the name.

Coiter reprehends *Falopius* and *Platerus* for this appellation, because, saith he, in this cavity there are holes and windows, and diuers windings which a drum hath not. To whom we answer, that in men it hath the name of a Drum or Tympane from the vse; but in brute Beastes not only from the vse but also from the figure, because in those creatures that chaw the Cud it is very like to a Turkish drum. This cavity is also called by *Coiter* and *Placentinus* the *Bason* & the *Denne*. It is excavated or hollowed in the beginning of the stony bone, betwixt the roots of the *Mammillary* prolesse, and the place where the head of the law is inserted or fastned to his ioint. The vtter part thereof regardeth the hole of Hearing from which it is onely separated by the membrane [tab. 10, fig. 2, from h, toward c.]

Coiter's object.
Answered.

Hence it is that if the inside of the eare bee inflamed or vlceraed, vpon the motion of the Note, lower iaw the patient is pained in his eare.

The inner part of the cavity is by a thin scale distinguished from the hole of the sleepe artery [tab. 10, fig. 2, from h, to L.]

This first is the greatest cavity of the three, and by a successiue ingresse or continuity of passage is ioyned with them, by which meanes it is able to containe a greater quantity of inbred aire, and also receiue at the same time diuers sounds comming from diuers quarters.

But because the internall aire must first be moued by that which is without, and then transport the image of that sound wherewith it is moued to the auditory nerue, it was very necessary that it should be purged and kept pure from any stayne of corruption, that like a neate glasse it might represent the image offered vnto it. For this purification and expurgation of the inward aire, Nature hath placed in this cavity diuers instruments: some seruing for Pulsation, some for Traiection & some for Expurgation. For Pulsation serue the three bones, the chord and the muscles. For Traiection or conduction vnto the other cavities serue two perforations commonly called *Fenestella* or the windows. For Expurgation there is a passage which leadeth into the pallar. All the particles did require a large cavity, whence it was that Nature framed this stony bone long and round, that so it might containe the more. Furthermore, this cavity

The organs in
this cavity.

Why this is
single.
A witty conceit
of *Aquapendens*

is but single, whence it comes to passe that though there be many noyses made together, yet they are at the same time receiued. For if this first cavity had bene distinguished into many dens, neither would the sounds haue bene receiued at the same time nor after the same maner intertained & iudged of by the faculty, for the diuersity of reception would also haue induced a diuersity of apprehension, as *Aquapendens* very wittily hath obserued.

The fashion of
the cavity.

The interior superficies or inner surface of this cavity is vnequall, being in some parts depressed and thrilled through, in others knotty and swelling. Immediately behinde the membrane it runneth vpward toward the forepart, where also it becommeth narrower, afterward it is dilated and tendeth backward toward the top; then as if it were another cavity it is produced or lengthened downward; which part saith *Coster*, in a man is like a bladder. [table 11, fig. 8, and 9.] In a calfe like a waggens budget, in a kid and lambe like a market womans pouch. It is also rough and spongy; rough, that it might receiue the sounds and not reflect, returne or double them, for if it had bene leuigated, that is, smooth and equall like the arch of a Church, it would haue returned an Eccho. Spongy also, that if at any time the noyse should happen to be so strong that it might offend the hearing, the force thereof might be abated in those small holes. Moreover, in that spongy porosity the Inbred ayre is laboured and brought to perfection. But when I say, it is spongy, I would not haue you conceyue that it is soft as a sponge but porous, for otherwise it is exceeding hard and stony, thereby yeelding and returning a quicker sound.

Why porous
or spongy.

How lined.

Againe, some parts of this cavity are lined ouer with a membrane produced from the *Pericranium*; for after the *Pericranium* hath framed the membrane of the Tympane, it is duplicated and diuersly diuided, so as some of it doth inuest certayne parts of this cavity.

The necessity
of the parts of
this cavity.

But because this cavity was destined for the reception of the implanted or Inbred ayre, which was to receyue the outward ayre altered by the sound, it was very necessary that it should receyue some kind of percussion: but being by the membrane distinguished or diuided from the hole of hearing, it could not receyue the alteration of the outward ayre without some other helpe, which helpe is pulsation, and that pulsation is accomplished by the three bones, the chord and the muscles.

Now that the Internall ayre being affected by the pulsation of the outward ayre altered by the sound, might carry this affection vnto the sense, there was made certayne canales wherein the inward ayre might be conuayed vnto the auditory nerue, to wit, the two *Windowes* with a passage into the *Labyrinth*. Furthermore, it was also necessary that this implanted ayre should be preserved pure, as also bee cherished and sustayned by the ayre which wee draw in at our mouths, to which purpose Nature hath created a canale or passage out of this cavity into the pallate, by which it is purged and receyueth new ayre for his perpetuall nourishment. Of the Instruments seruing to pulsation, we haue entreated at large in the seuenteenth and eighteenth chapters; of those seruing for expurgation very particularly in the nineteenth chapter; and both wee haue repeated in this. It remaineth now that wee prosecute those Organes which serue for Traiccion or transmission of the affected syre vnto the auditory nerue, and so to the first sensor.

CHAP. XXI.

Of the two Windows called *Fenestella*, and the water course in the first cavity.

The first.

Fenestra ovalis

IN this cavity there are two holes very small, which some men call *Fenestra* or *Fenestella* the windowes. These regard the orbe of the hole of hearing as from a higher place. The first which is the foreward and the higher and looketh toward the face, [table 8, figure 4, and 5, F. table 10, figure 2, k.] being as it were in the midst of the cavity, is of an Ouall figure or like an Egge, and therefore it is by some Anatomists called *Fenestra ovalis*, the ouall window.

It is somewhat long and flatted on the sides, and in the backe side it openeth it selfe into the *Cochlea* or the least cavity with a large mouth and becommeth so like the forepart of the *Cochlea* that a man cannot tell whether that this Ouall window open into the *Cochlea*, or the *Cochlea* into it. This also ioyneth it selfe with the posterior hole, and passing inward is dilated, and maketh as it were a Marker place or is like the cavitie of a mettall Mine, (for thus the anatomists haue pleased to compare litle things with great) from which many streets,

wayes

wayes or burroughs do run. Vpon this lieth the basis of the stirrop, and for the most part closeth it vp.

The other hole or window is the posterior and lower. [*tab. 8. fig. 3, 4, G, tab. 10. fig. 2. l*] It is round and lesse then the former and somewhat narrower in a man; but in a Calse and a Sheep saith *Placentinus* it is somewhat larger, and a little extuberating or bunching out; alwayes open it is and declining toward the backside of the cavity, and yflueth together with the former through the bone making a double canale.

Betwixt these two windows [*tab. 10. fig. 2. k and l*] about the lower hole is there a little knob or protuberation, which together with the round hole and the strutting bunch placed vnder the vpper part, may be compared to the little bosse (saith *Placentinus* and before him *Vesalius, Coiter* and *Platerus*) wherewith they vse to adorne the cheeks of a horses bit. In this lieth the chamber of the third cavity which is called *Cochlea*, of which we shall heare more in the next Chapter.

The vse of these windowes is, by pulsation to receiue the sound communicated to the implanted ayre, and to transmit the same to the other cavities that follow.

The lower hole is clouen into a double pipe which ly one vpon another [*tab. 10. fig. 2. i i*] and are diuided onely by a thin bony scale, the one of them together with the Quall window passeth to the *Cochlea*, the other goeth into the Labyrinth or the second cavity of the stony bone. The more forward of these admitteth a surcle of the Iugular veine, and sendeth out a branch of the first coniugation. The posterior is compared to a Water-course [*tab. 8. fig. 3. H, tab. 10. fig. 2. g*] because it is like the pipes wherein water is conuayed, imagine it to be in a Serpentine Still, some call it the Snayly pipe. The Ancients and *Galen* call it *Cacum meatum* the blinde passage, others *Capreolaxis*, that is, writhen or intorted, not because it is blinde, but because if you put a Hogges bristle into it, it will hardly finde an yssue. And truely in the dry skull of an Oxe you cannot finde way for a bristle by any meanes.

It passeth writhen, first forward then backward obliquely about the hole of the first cavity. From thence turning downwards it determineth into the fift hole of Hearing. [*table 10. fig. 2. a b y d*] It is full of holes; in the beginning is that which is marked with [*a*] commune to it with the vpper part of the passage of the auditory nerue. Afterward in the middle of the passage on the outside in the forepart of this canale [*d*] it maketh the first hole of Hearing and letteth fall an artery; so also in the inside [*y*] at the beginning of the second cavity it openeth it selfe. In the end also it hath another hole [*b*] which determineth into the third bone of Hearing. Through this canale is the greater part of the auditory nerue as also an artery diuersly deduced and dilated. For because it was necessary that the branch of the nerue of the fift coniugation should grow hard, it was also fit it should be conuayed thorough the hardest, driest and most contorted passage, especially seeing there was no other way where through it might be conuayed.

CHAP. XXII.

Of the Labyrinth and the Cochlea or Snayle-shell, that is, of the second and third Cavities of the Stony Bone.

THe second Cavity because it is full of windings & turnings like a Conny-burrough, is called *Labyrinthus* and the Mine. It is insculped or excauated in the Posterior and anterior sides of the stony bone or in the root of his proeasse, and is distinguished or denided from the hole of the nerue of Hearing, onely by a thin scale. [*tab. 10. fig. 2. betwixt m and e*] It is round and lesse then the former: and when it hath (vnder the knob and behind the Quall window) ioyned it selfe to the following cavity; attayning inward it is dilated and maketh as it were a Market place, or the broad floore of a Mettall Myne as before is saide, from which many wayes run out, which proceeding thorough the hard substance of the bone like a hollowed circle, doe againe returne into a large Chamber.

These wayes we call burroughs with *Falopius, Coiter* and *Platerus*, or with *Placentinus* bony Semicircles. [*tab. 8. fig. 4, and 5. NNN, tab. 10. fig. 2. m 1, 2, 3, and particularly m with the Characters 1, 2, 3. fig. 6. V*] Of these we make three, which do so passe that two of them do twice interse& themselves with right angles, but the more manifest intersection is made about the top of the third cavity where the hole endeth which receiuerth and transmitteth the nerue of the fift coniugation-

In their originall they are ample or large and become narrower by degrees, because it was not fit that the Sound should passe through a broad space; afterward running through the substance of the bone in circular reflections, they returne to their beginning, yet so that in their whole progresse they neuer manifestly open one into another.

The first.

One of these (which is the lower) runneth from the forepart of the cavity diuerting or turning aside outward yet still in the same cavity, afterward it is reflected and runneth thorough the posterior angle.

The second.

The second issueth out of the same anterior angle, and arising vpward after it hath made a semicircle, it returneth through the posterior angle.

The third.

The third ariseth and determineth in the backward angle of the cavity: for beginning there, it perforateth the bone with a circular cavity tending outward, and so returneth thither againe. And all these in young Infants may be separated whole from the cavity and from the crust wherewith the bone is lined, but in time they grow stony and are vnited. These canals or burroughs could not be made long because of the shortnes of the stony bone, although it had beene very profitable, because length maketh the sound be better perceiued. Wherefore Nature recompenced their shortnesse with circunvolutions, and indeed the gyrations do better helpe the Hearing then length would haue done, because in them as it were by degrees the sound is by little and little laboured, and ascends broken and diuided into the braine. Furthermore, the burroughes in their inward superficies are inuested with a very soft and fine membrane.

The reason of the meanders.

Their perforations.

These burroughs by their egress and regress into this cavity make fixe holes: beside, from the first cavity into this are two holes, and moreouer certaine small ones from the lower hole of the auditory nerue and from the common canale. [table 10. fig. 2. 7] The cavities or holes, saith *Aquapendens*, are so innumerable and intricated one with another, that it may well be called a Labyrinth. For their number they are rather to be admired then numbred, neither can a man finde any order in them, and if any man should attempt any such thing, it were a worke of a vaine and addle witte, albeit *Placentinus* thinketh it feasible. For cut any part of this bone, and beside the vmoost crust you shall finde the rest of the whole bone to be full of holes, pores and dennes, yea altogether spongy, as is touched partly before.

The vse of the conuolutions.

The vse of the Conuolutions and Meanders is, that the sound being conuayed through so narrow passages might be more sharpe and not be dissipated; and this we may see in Instruments of musick, for a Flute or Corner by how much it is the longer and the narrower, by so much is their sound more shrill: the reason is, first because the ayre remayning quiet and at rest in the canale doth more easily receiue the alteration proceeding from the sound then it would doe if it had scope wherein it might be troubled and disturbed. Again, the ayre concluded in a narrow roome is not dissipated but vnited, and so remayning yeeldeth a greater & quicker representation of the sound vnto the nerue, then it would do if it were dispersed.

The third cavity.

The third cavity is called *Cochlea* or the Snail shell from the sinuing obliquity of his passage; which elegantly resembleth the wing of a Snail or Periwinkle shell [tab. 8. fig. 4. and 5. O. tab. 10. fig. 2. vnder n] especially if you take off the vpper part of the shell till you come to the narrower part thereof where the scruiing begins to be thicke. *Vesalius* calleth it *Antrium Buccinosum*, the Den like a Trumpet. The Ancients called it the blind hole or the blind cavity, because they thought it had no through passage. But the truth is, that though it be much intorted and writhen, yet it hath an yssue in the midst, in that place where the gyrations are fastned from the beginning to the end, and this yssue is narrow and direct. For if this cavity had beene blinde without an out-let, the ayre being beaten could not haue attained to the nerue of Hearing.

Where situated.

This is farre lesse then the former two, scituate in the forepart of the proceffe vnder the knub of the first cavity, that it might meete with the Sound which proceedeth from behinde forward, and is distinguished from the canale, which we saide was like a watercourse (placed in the midst of the stony proceffe) by a thinne bone like a bridge. [table 10. fig. 2. betwixt n and f]

The figure.

It is long and crooked and hath three gyrations sometimes, sometimes foure, one of them receiuing another after the manner of the *Cochlea* or Snail shell, by which it is intorted somewhat inward and downeward. But the broader scrue standing highest receiue the nerue; the narrower standing lowest determineth in the cavity of the bone, and worketh it selfe also a passage. Into this endeth the hole of the first cavity called *Fenestella ovalis*, which *Platerus* calleth the lower hole and *Placentinus* the vpper [table 10. fig. 2. l] I meane into the greater gyre of this bone.

This

This bone of the *Cochlea* or the *Snail* shell consisteth of two kinds of circles, whereof one is made of a bony substance very thin and dry, which may easily be crumbled, and on euery side like a *Snake* rowled vp into bights. The other was first propounded by *Eustachius*, *Eustachius*, which is made of a soft and mucous matter yet firme and hath I know not what kind of sandy matter mingled therewith. It ariseth out of the middle space of the first conuolutions, as it were out of a large basis, and being by degrees extenuated, endeth in a sharp point but it ascendeth not so high as that it toucheth the circumference of the bone whereinto the first gyrations doe determine.

This wonderfull prouidence of our Creator, *Empedocles* as *Galen* witnesseth in his Booke *de Historia Philosophica*, did first intimate, when he saith that the sense of hearing is made by the impulsion of the ayre, or of a spirit which striketh and beatech the part like a *Snail*es shell, suspended within the eare like a bell. And with him agreeth *Aristotle* in the 11. Chapter of his first Booke *de Historia Animalium*, where he saith, that the inward eare which is like the contortions of a *Snail*es shell, endeth in a bone which is like the outward eare.

This third cavity as also the second and the burroughs thereof, are inuested with a soft and thin membrane, after the same manner that the sockets of the teeth are. *Vesalius* saith it is a part of the nerue of the fifth coniugation, and that it doth inuest but some parts onely of the cavity, not all throughout. Into this cavity as well as into the former do run three or foure holes so small that a haire will scarce passe through them, yssuing out of that canale through which we said the auditory nerue doth passe; through which holes certaine nerues of the first coniugation, or at least their faculty is communicated to the foresayde membrane. So differeth *Bauhine* from *Vesalius*.

And although it is generally beleued that the sense of hearing is especially made in the first cavity, yet it cannot be denyed but that it is also made in the others; seeing into them as is said, there are furcles of nerues deriued, and in them also Animall spirits and Inbred ayre is contained. Notwithstanding the two hindmost cavities were rather made to hinder an *Eccho* or reflexion of the sound to the first cavity. And whereas these cavities haue holes of diuers magnitude, length and figure, it is reasonable to think that they were so framed for the difference of sounds. For a base sound and a great quantity of ayre require a large hole.

The length prohibiteth the *Eccho* and the reflection of the sound, wherefore the greater sound required longer canales, and the lesser shorter, that the sound in them might as it were, be appeased, and an *Eccho* prohibited. The variety of the figure maketh much either for the naturall dilatation or transmission of the sound and the ayre, which runneth for the most part through circled meanders; or that the sound in them might rest: now we may easily imagine that a sound will sooner cease or be appeased when it runs through many turnings or gyrations then it would doe if it were conuayed by a straight line.

But the vse of this third cavity *Cotter* elegantly sheweth and confirmeth by an instance in a circled instrument, put case it bee a *Sackbut*. For if a man lay his eares to the holes of such an instrument, he shall here a wonderfull whistling and hissing noyse and murmure: where if a man blow into it with his mouth it will sound like a *Trumpet*. And thus much concerning the stony bone and the cavities thereof: now we proceed.

CHAP. XXIII.

Of the Nerue which arinueth at the Eares.

At length we are come to the Auditory Nerue which maketh that coniugation which is commonly called the fifth. [tab. 21. lib. 7. fig. 1, 2, 4. tab. 15. lib. 7. fig. 20. M] It yssueth out of the transuerse proceffe or bridge of the *Cerebellum*, and is a thicke and large nerue; therefore neereft of all to the After-braine because it was to conuey a great quantity of Animall spirits. It insinuateth it selfe into the first hole of the stony bone, with a large perforation and made of purpose within the scull for the transmission of this nerue, which it hideth all the way it runneth foreward, till in the middle almost of the stony proceffe it is diuided into two vnequall parts: the one large and ample, the other small but harder; harder I say then the other, not through out the length of it, but onely in that part which is longer then the former. For (that we may say so much by the way) the softnes or hardnesse of a nerue dependeth vpon 3. things First, vpon the

Where it ariseth

How many waies a nerue becomes hard and soft

the originall, so those nerues that arise out of the Braine it selfe are the softer; those that arise out of the After-braine or out of the spinall marrow are the harder. Secondly, vpon their distance, as they are farther from their originall, or neerer vnto it. So the Opticke nerues are the softest of the whole body, because they are neere to their originall; the nerues of the hands and feete the hardest, because they are farthest off. Or, thirdly, it hangeth vpon their contraction: for from their contractions with hard bodies as bones and gristles, or with soft as fat and vessels, they become harder and softer as *Placentinus* hath obserued, but this by the way.

2. Branches.

Small threds
of the audito-
ry nerue.

Why those
that are borne
deafe are also
dumbe.
The very
nerue of
hearing.

This slender production of the nerue through the vpper hole of the fore mentioned passage entereth into that secret bony canale which we called the *Watercourse*, and so creepeth toward the forepart of the head. Afterward it is reflected and entereth into the first cavity, and falling downward and backward, it yssueth out of the bone at the roote of the lap of the eare, and is subdiuided into three especiall branches. The larger and vpper runs out into the fore-side and the backside of the roote of the outward eare. The lower deriued through the iaw, is distributed into the *Masseter* muscle and the first muscle that mooueth the cheeks. The third which is the middlemost is very small and Capillary, and is disseminated into the glandulous and membranous parts about the roote of the eare. There are also other threddey surcles which are spent into the muscles of the larynx or throte, and of the bone *Hyois*. And this is the cause of the consent betweene the eares, the tong and the larynx. Hence also it is that when the auditory nerue is originally and in the first conformation obstructed, those that are borne deafe are also dumbe; and thus much of the lesser part of the nerue.

The thicker part of the nerue which is soft, and is properly the *Nerue of Hearing* because it of it selfe is the cause of this sense; is led through the hole of the foresaide passage and runneth out into the dens or caues of the stony proesse: yet the larger branches doe determine in the first cavity as being the largest and of most vse, where they are dilated like a membrane and make the chiefe instrument of hearing. Wherefore the receiued opinion is, that in this cavity the sense of hearing is especially administred, because into it the animal spirit entreth through the nerue, and is there mixed with the Inbred ayre. Out of this one cavity through small perforations of the fore said cavity run certaine small threds into the other two cavities, which are communicated to the membrane wherewith they are compassed.

The vse of it.

The vse of this nerue is (according to *Galen* in the sixth Chapter of his 8. Booke *de usu partium* & *Auerrhoes* 2. *Collect.*) to be the Organ of hearing, and to receiue the sensible object that commeth from without, and to leade the images of the sounds vnto the braine as vnto their competent Iudge and Censor saith *Laurentius*.

The Chord.

But from a branch of the fourth coniugation of the braine, there departeth a very small surcle, which with a winding passage entereth into the cavity of the Eare neere the bony canale which goeth to the palate, then it cleaueth obliquely to the Tympane, and after to the Hammer about the insertion of the muscle, and proceeding on perforateth the stony bone in the backside of the hole of the hearing: then, a little reflected, it creepeth downward till it meete and ioyne it selfe with a smaller and harder branch of the fift coniugation. This *Eustachius* calleth a Nerue, others call it the chord or thred which, say they, runneth through the middest of the membrane of the Tympane; but whence it ariseth and whither it would, or whether it be a nerue or an artery, they freely confesse that they are ignorant.

Eustachius.

CHAP. XXIV.

Of the Implanted or Inbred Ayre.

Galen in his seventh Booke *de Placitis*, speaking of the instruments of the senses determineth; that the instrument of sight is lucid or bright, that of the hearing aereall, that of the Smell vaporours, that of the Taste moist, and that of the Touch earthy. Wherefore when we say that the instrument of hearing is ayry, or like vnto ayre, we vnderstand that it is a part of mans body (taking the word Part in a large signification) which imitateth the nature and condition of the ayre.

This ayre of which *Plato* among the Philosophers made first mention, is seated in the eares from the first originall of our generation in the wombe of our mothers. I meane as soone as there were emptie cavities hollowed in the bones, all which are filled with this ayre.

And

The objects
of all the senses,
Plato.
How this ayre
is generated.

And therefore the Ancient Philosophers and Physicians, yea *Aristotle* himselfe in the eight chap. of his 2. Book *de anima*, and the 83. text called it *implanted*, or *Inbred*. Others call it *Congent*, *implanted*, *complant* & *inedificated*. It is made of the airy part of the seed and that very pure, to which the purest airy part of the mothers blood applyeth it selfe, saith *Archangelus*.

The names of
it.

This aire is contained in the cavities of the eares; which may be proved, because all the dens and cavities excepting the first in which are the smal bones the muscles & the chord, are empty; seeing therefore there is in Nature no vacuity, it is necessary that these empty cavities must be full of aire.

Where contained.

This aire is thin, pure, without any sound at all, immovable, plentifull and separated from the externall ayre. *Thin and pure*, that it might more readily and more perfectly admit any externall sound, for through a crasse and cloudy ayre the sound is not so freely caried, but heard with more difficulty; whence it is that a mans voyce in winter is baser then in summer, because as saith the Philosopher in the 17. Probleme of the 11. Section, both the inward and the outward aire is thicker in Winter then in Summer, now being thicker it is mooved more slowly.

The nature of
this ayre.

Pure.
Arist. Problem.

This ayre is *without any sound*, and therefore in the night we may hear better because there is no noyse stirring, as *Aristotle* teacheth in the 33. Probleme of the 11. Section. Ad hereto that which he in the same place addeth, that in the day time the ayre is dense, because it is filled with light and the beames of the Sunne, but in the night more rare, because the fire and the beames are departed thereout.

Without sound
Arist. Problem.

Wherefore the outward ayre which is altered by sounds, and like a waue of the Sea boundeth to the eares is not admitted into the inward eare, neither doth it touch the implanted ayre; for if it had, the sense of hearing would haue beene imperfect and the Instrument would soone haue beene vitiated, which *Aristotle* proueth by an instance in those that yawne, in the 29. Probleme of the 11. section, and in his 5. Book *de generatione animalium* and the 2. chapter. For when we yawn we cannot heare so distinctly, because much of the ayre we breath forth getteth into the eares, insomuch that we may sensibly perceyue the motion thereof; for when the internall aire resisteth the occuration of the outward there ariseth a noyse in the eares, which noyse as also the circumaction or disturbance of the spirit hindreth our hearing whilst it be againe appeased.

Aristotle in-
stance.

Why wee can
not heare well
when we
yawn.

Againe, it was necessary that this implanted aire should be *immovable* by it selfe or of it owne nature, that it might exactly receiue all the differences of sounds, of *motions* saith *Aristotle* in the eight chap. of his second Book *de Anima*. Others say, it is immovable because it is not moued by any other but remaineth alwayes the same in the eares. Others because it hath no naturall sound but is fit to receiue all differences of sounds saith *Laurentius*. But that the inward aire ought to be quiet and immovable may be proued by the indisposition we haue in our hearing when we are troubled with hissing or singing noises in our heads. Yet is this ayre mouable not of it owne accord, but because it is moued with the least impulsion of the outward aire and is stirred with local motion; for when the outward aire moueth the membrane of the drum, the internall aire is also moued, that it may receiue a forme like to the forme of the sound which is made.

Immovable.

How it is
mouable.

It is *Plentifull*, for plenty is required for the full reception of the sound; some say that it may be able to receiue many sounds offered vnto it at the same time, but *Placentinus* saith, it doth not receiue many sounds because of the multiplicity of the parts thereof, because each sound is receiued by euery little particle thereof.

Plentifull.

It is *separated from the externall Ayre* by the interposition of the membrane of the Tympane, least the Instrument of Hearing should bee offended. For if the externall Ayre should haue gotten into the inward Ayre; if it had beene eyther too cold or too hot it would haue violated the Auditory Nerue, and by continuity the After-braine also and the Braine it selfe. Moreouer, if the externall Ayre should haue beene immediately ioyned and commixed with the internall, seeing the externall is in perpetuall motion, thicke, impure, oftentimes also smoaky and full of small creatures, it could not haue beene auoyded but that the Hearing would thereby haue bene impaired if not perished; for the inbred ayre also would haue become thicke, smoaky, and also filled with those small Animals. It would also haue sometimes hapned in violent motions of the outward ayre, that the inbred aire and with it the Animall spirit must haue beene shouldred out of their proper place and the hole of Hearing quite rammed vp. Furthermore, this benefite wee haue by the membrane that separateth the externall from the implanted ayre, that if a man bee vnder water, the water cannot

Neither is this implanted aire of the same nature that the outward ayre is of, but hath onely a similitude therewith, which we may gather out of these words of *Galen*. *Neither is euery Instrument of sense changed, altered or affected by euery sensible object: but that which is bright and light some is altered by colours, that which is aery by sounds, that which is vaporious by odors, and in a word that which is like is familiar to his like.*

Wherefore we esteeme the nature of this ayre to be the same with the animall spirit which also is aery, and that there is the same maner of the conuersation and refection of the one and of the other. For this implanted ayre is successiue generated and againe dissipated, as the Animall spirit is continually spent in the animall actions, and againe euery day regenerated. In like maner this ayre that is bred in the eare is (at least a part of it) continually dissipated and generated againe; for if it should altogether be exhausted or spent we should vtterly lose our hearing. Now it is strengthened and hath his refection from the ayre which wee draw in by our nozethrils and through our mouths, especially by that which entreteth at the mouth, for there is a patent and open passage thorough the Canale which we haue before spoken of out of the mouth into the Eares, by which passage also wee sayd before that the Eares were purged.

Simplicius the Philosopher hath deliuered, not that this ayre is like the animall spirit, but that it is a thing animated or hauing a life of it owne, wherby it subsisteth. *Coiter* calleth it a part of the Soule, *Archangelus* conceiueth that it is nourished by blood, whose opinion we will heere set down, that those that list may iudge of it.

The aery body (saith he) is nourished by blood brought by the veines, and that *per Diadosin*, that is, by Transumption, as the cristalline humour of the Eye is nourished by the glassie humor, by this *Diadosis* or transumption. For there redoundeth out of the glassy humor as much as is sufficient for the nourishment of the cristalline, like as the glassy humor transumeth from the membrane called *Araña* or the *Cobweb* an Aliment accommodated and proportionable to it selfe. And this commeth to passe after this manner. In the Coate called *Araña* or the *Cobweb* there are veins by whose blood it is nourished. After the Cobweb is satisfied, that which redoundeth or is superfluous is transumed by the Glassy humor: when the Glassy humor is satisfied with nourishment, that which remaineth is transumed by the Christalline humor as a fit nourishment for it, so that the Christalline is nourished by an Aliment, prepared by the vitrious humor, and the vitrious or Glassy humor is nourished by an Aliment prepared by the Cobweb, to wit, either of the others superfluities or leauings.

The same happeneth in the aery instruments of hearing. For the membrane that inuesteth it receiueth veines and is nourished with their blood: that which aboundeth beside the nourishment of the membrane, being now far altred from the nature of blood is attracted and transumed by that aery body into his proper nourishment. But that this instrument of hearing might haue not only venall nourishment but arteriall life also, and with it all the parts that are subordinate and ministring to it; there are certaine arteries which are deriued into the structure of the organ of hearing. Thus far *Archangelus*.

Concerning the vse of this implanted ayre our Authors are full of diuersity. *Aristotle* in the 10. Chapter of his second Booke *De partibus Animalium* and in the second chapter of his fift Booke *De Generatione Animalium*, calls it *Audiendi sensorium*, the very sense of hearing it selfe. And truly the Ancients haue all deliuered that it is the chiefe and principall Organ of Hearing, and from hence it was that *Aristotle* sayd that the Nature of Hearing was aery.

Mundinus sayth, there is an audible spirit in the cavity of the stony bone which is the instrument of Hearing.

Carpus thus. The implanted ayre receyueth the species or formes which are brought to the sense of Hearing.

Varolius. The included aery spirit is the proper Instrument of Hearing.

Coiter. This ayre is the first and principall organ of Hearing, yea a part of the Soule.

Archangelus. It is the most principall Instrument of Hearing, which the Faculty vseth in the perception of sounds and voyces, and in iudging of them.

Aquapendens. The office of this ayre is to receyue outward and externall sounds, and so it is the principall author of Hearing.

Placentinus. It is the matter which receyueth the Sound, the Medium where-through it is

transported. For after it hath receyued a Sound it doth not conceyue it or iudge of it as being a thing inanimated, now no action of the Soule can be performed by that which is not animated.

Laurentius. This Ayre is exceeding necessary to the Sense of Hearing, without which I can scarcely conceyue how we should heare at all; but that it is the principall organ of hearing, I could neuer be perswaded, especially because it is not animated, but rather I belceue it to bee an internall *Medium*.

Finally our Author *Bauhine* setteth downe the vse of it in these tearmes.

This Aire the faculty of hearing vseth as an internall *Medium* for the susception and transvection or transportation of Sounds and voices to the auditory nerue, by it to bee discerned, like as in all the instruments of the other senses there is required a double *Medium*, the one outward the other inward. Inward, as in the sight the watery humor, in the Taste the spittle, in the Smell the spongy bones, in the Touch the skinne is the internall *Medium*, (although I know *Laurentius* would haue it the Cuticle) in which the formes or *Ideas* of things are separated from the things themselues, and so naked are transported vnto the first *Sensator*. In like maner the implanted aire is gathered in the inward eare, to receiue the abstracted formes of the sounds, and to transport them or conuey them vnto the sense.

Againe, as in all the instruments of the senses the internall *Medium* is distinct, and a differing thing from the principall Organ to which the action particularly belongeth; as in the Organ of sight the watery humor is thought to be the internal *Medium*, but the cristalline the principall part receiuing the representations, but not iudging of them: so in the hearing the internal *medium* is this implanted aire; but the principal part is the auditory nerue, which yet doth not iudge of the *Idea*, but conducteth it to the braine, that is to the first *Sensator*.

CHAP. XXV.

Of the maner of Hearing and of the Nature of Sounds.

Considering that to intreate of the maner of Hearing belongeth rather to a Philosopher then to Anatomists, we will be but brieue herein, yet something we thinke good to say because the structure of the eare was for the most part vnkown to the ancients.

The Eare is the instrument of hearing, and the action of the eare is the sense of hearing; vnto this Sense there are three things required: an Obiect, a *Medium*, and an Instrument. The Obiect is that which is audible, that is, all Sounds. A Sound is a quality issuing out of the Ayre (Coiter addeth, or the water) beaten by sudden and forcible collision or concurrence of hard and solid bodies, and those smooth, concavous and large. This definition we will labor to expaine in this following discourse. The *Medium* is cyther Externall or Internall. The Externall *Medium* according to *Aristotle* is Ayre or Water, but in water the sound is but dull, as a man may perceiue when his head is vnder water: yet they say that Fishes can heare in the water very well, as they can assure vs that vse in the night time to fish for Mullers. And although the ayre going into the water do make a sound; yet this sound is made in the Ayre and by the interposition therof, though it be made by the water.

The Internall *Medium* is the implanted Aire concluded within the denues or cauities of the eares. The Instrument although we may say it is the whole inward eare furnished with his cauities and other parricles aboue expressed, and although that generally the Philosophers and Physitians do determine that the inbred aire is the especiall and proper Organ of hearing; because as in the Eye the cristalline receiueth the obiect, that is, the light: so this inbred aire receiueth the sound. Yet we are of opinion that not this aire but the auditory nerue is the principall instrument. For we thinke with *Galen*, that not only the alteration or reception which is made by the inbred aire is the sense of hearing, but also the dignotion or iudgement of that alteration. Wherefore sounds and voices are transferred by this ayre to the auditory nerue, as vnto the substance that is apprehensue, and from thence to the common sense where they are exquisitly iudged of. For if they must be knowne and perceiued, then must they touch some substance indued with sense, because all action is by contraction. Now the sensatiue faculty is not transported out of the body, and therefore it was necessary that the sound should apply it selfe to the eare.

The Sound is generated of hard bodies mutually striking one another, as of the Efficient

Plecentinus.

Laurentius.

Bauhine.

An inward & an outward *Medium*.

That it is not the chiefe organ of hearing

Three things required to Sensation, Obiect, Definition of a Sound, *Medium*.

3. Instrument.

How sound is made.

ent cause, (for soft bodies doe easily yeeld, not resisting the force that is offered vnto them) and is receiued in the aire as in his matter : this Ayre accompanieth the Sound, and carryeth it as it were on his wings ; for as the ayre is moued so also is the Sound carried as wee may perceiue by a ring of Belles farre off from vs : for when the winde bloweth towards vs wee shall heare them very lowd : againe when the ayre is whiffed another way, the Sound also of the Bels will bee taken from vs. So also when two hard bodies are smitten the one against other, wee see the percussio before wee heare the Sound, for wee do not heare the Sound before the ayre that was moued doe bring the Sound with it to our eares, neither is that motion made in a moment but in time, and is carried swifter or slower as the percussio of the resisting bodyes was more or lesse vehement and quicke (for this the Philosopher requireth in Sounds) and consequently the repercussio or repulse of the aire. So wee see in a Drum if the skin of Vellam be moyst and lax, either they will not sound at all, or they make but a dull noyse.

How the sound
attaineth to
the eare.
A fit compar-
ison,

Vndam vocalem.

The Aer being affected with the quality of the sound driueth and altereth that ayre that is next it, and so by succession till the alterations come to the Ayre that is next to the outward Eare, even as when a stone is cast into the water it stirreth vp circles which driue one the other till the water moue against the brinke, or if the water bee broade doe of it owne accord determine. In like manner by the percussio of the Ayre there are generated certaine circles which moue one another till by succession they come to the organ of hearing: which continuation of the aire thus beaten *Anicen* and the ancient Anatomists call *vndam vocalem*, the vocal waue.

But if the stone be great and violently throwne into the water, so that it driueth the circles vehemently to the brimme of the pond, then will those circles be repelled againe and so run doubled and hudling to the first circles. In like manner if we hallow or speake aloud against any arched place, or against a wood or a mountaine, the voyce will be doubled and an Echo will answer vs.

What aire is
fittest to re-
ceiue a sound.

But all ayre doth not alike receiue a sound. For a pure thin and cleere ayre, which is vehemently and suddainly stroken by two hard bodyes whose superficies is broad, will sooner receiue the sound, and represent it more smartly then if the Ayre or the Bodyes bee not so prepared. A Needle strooke against a Needle will not make a sound though they bee hard bodies, because their superficies is narrow and not broad, and so in the rest. But above all, that Ayre which is containd in a concauous or hollow place, doth best receiue the species of soundes; because in the reflection there are many percussions besides the first; for the reuerberation of the Ayre maketh much for the increasing of the sound, which wee may see in dens, caues, woods, hollow mountaines, wels, and such like, which will not only returne againe the soundes that they receiue, but sometimes also the very articulated words. And thus much concerning the nature and generation of soundes, which is a meere Philosophicall disquisition, and therefore we passe it ouer more briefly. Now let vs come to shew how the outward Ayre that is beaten, is communicated with the implanted Ayre and the internall parts.

Diuers opinions
of the manner
of Hearing.

1. *Empedocles.*

But before we descend to this it shall not be amisse to let you take a view of the diuers opinions as wel of the Ancients as of the Moderne writers, concerning the manner how hearing is made, for vpon that very point we now are.

The first is that of *Empedocles*, who thought that this sense of hearing is made because the aire offereth a kind of violence to the inward part of the Eare, for because the inward Eare is intorted like a winkle-shel, and hangeth as a Bel in the steeple of the Body, it easily perceiuerth all appulsions of the aire.

2. *Alcmeon.*

The second is that of *Alcmeon*, who thought that we therefore heare because our Eares are within empty, for all empty things do resound if the sound get into them.

3. *Diogenes.*

The third is that of *Diogenes*, who saith, that in the head there is an aire which is smitten by the voice and so moued: against whom *Hippocrates* writeth in his Book *de carnibus*, where he saith, that there are some Authors of Naturall Philosophy, who affirme that the Braine yeeldeth a sound, which cannot be. For the Braine it selfe is moist, now no moist thing wil resound, but that onely which is dry.

4. *Hippocrates.*

The fourth is the opinion of *Hippocrates* in his Booke *De locis in Homine*. First of all saith hee, the Eare is perforated, and in that part wee heare, yet the emptie places about the Eares doe heare nothing but a confused noyse, but that which entereth through the membranes into the Braine, that is distinctly heard; where there is a perforation through the membrane

membrane which inuesteth the Braine. And in his Booke *de carnibus*, we heare because the holes of our Eares reach vnto the dry and stony bone to which is added a canale or fistulous cavity, against which hard bone the sounds do beate, and the hollow bone because of his hardnesse yeelds a resonance. Now in the hole of Hearing neere that hard bone, there is a thinne Filme like a Cobweb the driest of all the membranes of the body: but that which is the dryest is fittest to conceiue or receiue a sound as may bee prooued by many arguments. When this Membrane therefore yeeldes the greatest resonance then wee heare best.

The fift is *Platoes* opinion. The ayre that is implanted in the eare is beaten, that pulsation is transmitted into the principall seate of the soule and so we heare. *5. Plato.*

The sixt is *Aristotles*. Wee heare (saith he) when the ayre is mooued by two solide bodies, that which is beaten hath a plaine superficies that from thence the ayre might result; the concussion of these two bodies must bee vehement, that the ayre betweene them may not diffuse it selfe, but bee apprehended and smitten before his dissipation, for so onely the sound resulteth and filleth the ayre by continuation euen to the eare. Now in the organe of Hearing there is a certaine implanted Ayre. Hence it commeth that when the externall ayre is mooued the internall receyueth therefrom a motion and agitation (which otherwise of it selfe is immouable) so as it exactly perceyueth all the differences of the motion of the externall ayre. Thus is the Hearing begunne and perfected in the Ayre. *6. Aristotles.*

Seauenthly, *Galen* in the sixt Chapter of his eight Booke *De vsu partium*. It was necessary (saith he) that from the Braine a certaine surcle should be propagated downward to the eares, which might receiue the sensible obiekt comming from without, whether it were voice or a sound made by the percussion of the ayre; for the motion that is caused by such percussion diffuseth it selfe like a storme of winde or raine, or like a waue of the Sea till it ascend vnto the Braine. *7. Galen.*

Thus far the Ancients, who most of them, if not all, were ignorant or at least much to seeke in the exact Anatomy of the Eye. Among the later writers *Vesalius* and his adherents haue it thus. *8. Vesalius.*

A Nerue of the fift coniugation proceedeth through a torted and writhen passage, and extendeth it selfe into a Membrane where-with the hole of the eare is stopped, which Membrane being thin, dry, and well stretched and beaten by the outward ayre maketh a sound, being assisted by the hardnesse of the bone and his turning gyrations much like the shell of a Snaile or Periwinkle.

Columbus. So also we heare by the help of a nerue of the fift coniugation, which at the middle of the Labyrinth becommeth thicker, but yet maketh not the Membrane.

Massa saith, that the sound is made by the motion of the small bones, and thence wee heare. *9. Massa.*

Volcherus Coiter. The outward Ayre affected with the quality of the sound runneth vpon the Membrane or Head of the Drumme, which when it is beaten mooueth the small bones that are tyed to it. The bones strike the Nerue that runnes ouerthwart the Membrane. The same Nerue makes a repercussion vpon the membrane, whence it is that the ayre included receyueth the alteration and the sound. The Sounds without any disturbance are carried through the contorted Meanders of the Eares to the Auditory Nerue, which receyueth the Image of the noise, and presenteth it to the principall Sensor. *10. Coiter.*

Laurentius hath almost the very same in substance. The outward ayre (saith he) being stricken by hard and solide bodies and affected with the quality of the sound, alreth the ayre that is next vnto it, till by a continuation it come to the eares, where it first encountereth with the Membrane: the Membrane being stricken mooueth the three little bones and transmitteth in a moment the liuely Character of the sound, which Character is receyued by the implanted ayre, and through the windowes it sendeth it through these crooked and winding Labyrinths into the Snaile shell, from whence it arriueth at the auditory Nerue, and from thence is conueyghed to the common Sense as vnto an equall iudge or Censor. *11. Laurentius.*

Archangelus hath it on this manner as neere as I can vnderstand him. The thing that maketh the sound sealeth or stampeth in the ayre the species or forme of the sound, and withall driuerh it on vnto the Instrument of hearing which is also ayery that it might better receiue those species, and must likewise be mooued; wherefore the hole of the Eare standing

ding alwayes open (& in his inside supporting the stretched membrane of the tympane, behind which the aery instrument of hearing is concluded or shut vp, and to which the Anuile cleaueth) when the outward ayre attaineth to that membrane the Hammer beateth vpon the Anuile, and so it commeth to passe necessarily that the Instrument of Hearing (by which he vnderstandeth the implanted Ayre) is moued with the same motion that the outward ayre is moued, whence it is that altogether the same species or similitude of sound moueth the Faculty of hearing, which is brought thither by the outward ayre. Now the Nerues of Hearing do determine into the same place where this aerie instrument of Hearing is concluded, and a membrane made of the amplification of these nerues encompasseth that aery body, as the Opticke Nerues doe ariue at the Christalline humour. And as the Opticke Nerues do conuay vpon the wings as it were of the Animall spirit from the place of the Common sense the *Visine* Faculty to the Christalline humor: so these Nerues from the same Common sense doe transport the Faculty of Hearing to the principall organe of Hearing, that there might be a perception made of audible things. And so the Hearing when it hath apprehended the sound of an audible thing carrieth it to the Soule, and then the Reason or the intellectuall or sensatiue Soule comprehendeth and taketh knowledge of that which maketh the sound to be a Bell or a Drumme, or any other thing.

13. *Banquine.*

Finally, *Banquine* my Author (I call him so often my author to stoppe their mouths who would thinke that I should arrogate too much to my selfe if I should not acknowledge him from whom I haue taken most of this History) expresseth it on this manner.

The outward Ayre is an externall *Medium* which being driuen and moued by the mutual percussion of two hard bodies and affected with the quality of the sound, carryeth the sound which resulteth from that percussion vnto the Eare. The sound passeth through the hole of hearing which is alwayes open vnto the Membrane of the Tympane which it moueth.

That Membrane being moued, the implanted or in-bred ayre is also moued and receiueh the sound, or at least his Character or impression, and transporteth it out of the first cavity of the stony-bone thorough the hole of the Stirrop and the *Ouall window* to the other two cavities which we called the *Labyrinth* and the *Snayle-shel*. From thence it is conueighed to the auditory Nerue and to the originall thereof, that is the After-braine and so to the common sense as vnto a Iudge that is able to determine of the differences of sounds.

And because the Auditory Nerues are ioyned in the *Bridge* of the After-braine from whence they proceed, therefore all sounds are apprehended in one comprehension, not in two though there be two eares, that is, two organes of Hearing. But least the Membrane before mentioned should be driuen too much inward by the violence of the outward ayre when it is violently beaten, Nature prouided three small bones and two Muscles as we haue shewed before to preuent that inconuenience.

The vse of the hearing.
Aristotle.

The vse of the Sense of Hearing according to *Aristotle* in his Book *De sensu & sensibili* is to acquire or get knowledge and wisdom. For speech being an audible thing is the verie Cause of Learning. Again by the Hearing things are signified to our selues, as by our voice and tongues we are able to signify any thing to another, as *Aristotle* hath well obserued in the end of his third Booke *de Anima*.

A deprecation

And so much shal haue bene sufficient to haue spoken concerning the Sense of Hearing, wherein I finde that I haue great cause to entreate my Reader sanably to reade ouer this Discourse, and to pardon me if in some things I haue not so fully satisfied him; for there are some passages in my Author, wherein I haue bene intangled, partly by the difficulty of the matter, partly by the fault of the Printer, for in such a case as this the least error may prooue a sufficient *remora* or obstacle to interrupt the tenor of a Discourse, but as neere as I could I haue followed their words, at least their meaning, if they vnderstood themselves, as of some of them I make much doubt.

CHAP.

CHAP. XXVI.

Of the Nose which is the instrument of Smelling.

HAving absolued the Historie of those many particles which belong vnto the sense of hearing, wee will now come to the third outward sense which is the Smelling. As therefore we said in the Eare that there was an outward Eare and inward Eare; so must we also diuide the Nose into an outward and inward. The outward Nose carryeth with it, saith *Laurentius*, a kind of beauty, yea of maiestie; and the *Egyptians* in their *Hieroglyphicks* signified a wise and prudent man by a nose: and *Festus* calleth such wise men *Nasutus*, as if they were able to sent or smell the politicke stratagems of other men. Besides man, onely those creatures haue this outward Nose that haue foure feete and bring forth liuing ones, as for birds and serpens (saith *Aristotle* in the 16. Chapter of his second Booke *de partibus Animal.*) and those foure footed beasts that lay egges, they haue onely *μυστήρια*, holes of the Nose, which are not so compassed or formed that you may call them Noses; vnlesse it be because they breathe and smell by them. As for those Creatures which doe not breathe, they haue no Nose or holes at al, but other instruments of this sense, some smell by their gills, some by their *fistula* or pipe or trunke, some otherwayes as some of those we call *insecta*.

The outward
vie.

Nasutus.

Aristotels.

This outward Nose is called *πίρ* by *Aristotle* in the 11. Chap. of his first Booke *de Historia Animal.* and in the 16. Booke *de partibus Animalium*, as *Galen* in his Booke *de olfactus instrumento*. The word seemeth to be deriued from *πίρ*, because through the Nose the excrement and superfluities of the head doe fall away. Others call it *μυστήριον*, because of the mucous matter or phlegmaticke excrement which distilleth through it. If we should describe the Nose, we must say that it is a protuberating or strutting part of the face, making a way for the Ayre, for by we receiue it in and auoyde it out againe: some say it is a defence for the instruments of smelling, when as indeed they are not contained in the Nose, but remaine within the skull. Yet we will not deny but that it is an assistant to them, for if the Nose were away we should not smell without all question.

The names.

The reason of
the figure.

It is scituated betwixt the Eyes, for the part whereby we breathe ought to be in the midst and before. Nature therefore placed it in the midst betweene three other senses, the Sight the Hearing and the Taste, and in a straight line that the respiration might not bee interrupted but passe freely to and fro.

And situation

Moreover it is placed saith *Cicero* in his second Booke *de Natura Deorum*, aboue; because Odours flie vpward and therefore from aboue are more commodiously receiued. Add hereto that it standeth vs in good steed to smell our meats and drinks being so neere the mouth, which instinct Nature hath giuen also to brute beasts, as we may see especially in Apes who first smell to a thing before they will eate it. In a man the chiefe vse of the position of the Nose is for beauty and elegancy.

The Basis of the Nose aboue is broad and groweth into a blunt end downwards or rather, saith *Laurentius*, it beginneth with a sharpe point from the inward Angles or corners of the eyes, and endeth at the beginning of the lips.

It is diuided into an vpper part which is immoueable and bony, and a lower, which is moueable and gristly. The vpper part of the Nose called *Dorsum* or the backe is called in Greeke *πίρ* the spine or ridge of the Nose. The lower part where it enlargeth it selfe, into the Nostrils is called *ακρίον* by *Ruffus* and *Pollux*: the foote of the Nose, and the vtmost roundnesse *σφαίριον* the globe of the Nose or the tip as we commonly speake.

The diuision
of the nose.

Within it is diuided into two cavities by a hedge or partition which they call *pteryges*, *mares* the Nostrils, because in them the odors or odoriferous spirits or the Ayre doe innare or swimme continually; others cal them *μυστήρια* of the mucous matter that yssueth from them, others *τὸν πύλον τῶν ὀσφύων*, the holes of the Nose as *Galen* hath in his Booke *de instrumento Olfactus*.

And the names
of the parts.

The vse of the diuision is, that the action of the smelling might be more perfect, for in all the parts of sense (excepting the Touch) the sense is bipartite, because of the two sides of the body, the right and the left.

The vse of the
diuision:

In like manner saith the Philosopher in the 10. Chapter of his second Booke *de partibus Animal.* the power of the Nostrils is double or bipartite, but if they had bin disseuered or set aside as the eares they could not haue performed their office; because we smell euen in

our breathing, as also doe all other creatures which haue nostrils. Againe, by reason of this diuision one nofethrill remaines open when the other is obstructed, that thorough it we might haue the benefit of Inspiration and Expiration, and when both of them are obstructed the mouth may bee opened to supply their office, as wee see often in our Patients whose noses are stopped with a cold, they sleepe with their mouths open, drawing and yeelding their breath thereby least the man should be strangled.

The diuision
of each hole.

It is further to be noted that the holes of both the nostrils (which is but one in one nostrill) about the middle of the Nose are deuided into two parts, as *Galen* obserued in his Booke *de Odoratus organo*. The one part runneth aboue the palate into the vtmost part of the mouth and throate, whence it is that oftentimes we see that if a man laugh when he is drinking the drinke will come out at his nofethrills: and those Irrhines which wee cast into the nose sometimes for medicine, will fall into the mouth if the nose be close shut. The other part of the hole of the Nose ascendeth to the spongy bone. Finally, the outward parts of the Nose which compasse the holes are called *πτερυγια ala, pinna*, The wings of the Nose.

The Nose consisteth of a Cuticle, a Skinne, Muscles, Bones, Gristles, and the inward Coate.

The Skin.

The Skinne wherewith it is couered is thin, without any fatte that the quantity of the Nose might not exceed, which would haue beene a great deformity; but vnder the partition in the middle of the Nofethrills there is a rising or prominent fleshy particle neare the top of the lip, called by *Ruffus* and *Pollux* *κίον Columna* the Pillar, which in some men hangeth something outward; it is thicke and fungous so that it resembleth the Cartilage or Gristle, (from which notwithstanding we must learne to distinguish it) and in the compasse thereof stand many haire called properly *Vibrissæ*, becaute when we twitch them out it maketh vs shake our heads and sneeze, which is called *capitis vibratio*. The vse of these haire is, that those small Animals that fly about in the ayre should not be drawne into the nose in our Inspiration, but hang in those hairy springes.

The haire.

The muscles.

But becaute in deeper and sudden Inspirations and Expirations the motion of the nostrils serueth to no small purpose, therefore Nature made them mouable, and becaute they were to be moued according to our will and good pleasure, there are certaine muscles inserted into them, some seruing for dilatation, others for contriotion: the first open the nofethrills, the other shut them. Those that dilate the nostrils are foure: two small ones arising from the cheeke-bones, two others arise from the seame of the fore-head. There are also other foure which constringe the nose, two arising from the rootes of the wings, the other two are hidden in the cauity of the nose, vnder the coate which compasseth it about; but of these we shall heare more particularly in the Booke of Muscles.

CHAP. XXVII.

Of the Bones, Gristles, Vessels, Coate and vse of the Nose.

The bones.

He Bones which make the cauity of the Nofethrills are of two sortes: some may be sayed to be proper to the Nose although they be bones of the vpper Iaw, others are common. The proper are three: two externall and one internall, and these reach from the top but to the middle of the Nose, the rest is gristly.

The gristles.

The common Bones are one fixed at the vpper roote of the nose within, called *σπογγώδης* by *Hippocrates* and *Galen*, and neare it wee finde two other fungous and spongy bones which fill the vpper cauity of the nostrills made for the voyce and the Reception of odours, which are vnited by the bone *Cribri-forme*, so that some thinke them to be parts thereof: but of these in the History of the Bones.

Vessels.

The Gristles of the Nose are five: three are before tyed to the circumferences of the bones, and two make the wings, of which we shall intreat amongst the Gristles.

The coat or
membrane.

The vessels of the Nose are veines from the Iugular veines, arterics from the sleepe arteries, and nerues from the third coniugation of the braine on eyther side one.

The Coate (which *Galen* in his Booke *de instrumento olfactus* calleth sometimes a coate sometimes a membrane, but a membrane most Anatomists call it) which compasseth the capacity of the nostrills is, as *Vesalius* thinketh, an extension of a branch of the lesser rootes of the third coniugation of finewes. But *Columbus* and *Bauhine* take it to arise from the *Durameninx*, and it is the common coat of the mouth, the palate, the tounge, the *Larynx* or throtle,

Table 12. Fig. 8. sheweth the fore-side of the Skull, as also the bones, the holes or perforations and the Sutures both of the skull and of the upper Jaw: Figure 9. sheweth the Basis of the Skull, and many holes and Sutures therein.

TABVLA XII:

FIG. IIX.

IX

- AA*, A hole in the fore-head bone.
BB, The hole of the fourth bone of the vpper iaw, which is in the cheek.
C, A hole of the second bone of the vpper iaw in the inward angle of the eye.
DD, The fourth hole of the Wedge-bone in the outward side of the eye.
EE, The first hole of the same bone.
G, The second hole.
H, The third hole of the same bone in the scate of the eye.
II, The fore-head bone.
K, The left bone of the *Synclipter*.
L, The left bone of the temples.
M, The Mammillary proceffe of the temples.
NN, The Wedge bone.
III, The first bone of the vpper iaw.
Δ, The second bone of the vpper iaw.
Θ, The third.
ΛΛ, The fourth in the left eye.
Ξ, The fift bone of the vpper iaw in the Nose.
OO, The bridge or partition of the nostrils.
P, The Suture in the yoke bone.
Q, A part of second common suture from the first *N*, to *S*.
RSTVXTZ, The third common Suture drawne obliquely through the orbe of the eye.
aD, The first externall suture of the vpper iaw in the cheek, and from thence through the eye to *Q*.
b, The third externall suture of the vpper iaw from *b*, to *c*.
c, The second externall suture of the vpper iaw in the eye.
e, The fourth externall suture reaching to *z*.
f, The first externall suture of the vpper iaw in the middle of the Nose.
g, The second internall suture in the nose.
h, The seauenth externall suture of the vpper iaw.
i, A bastard suture of the vpper iaw at the eye.
Fig. 9. A, The end of the Coronall Suture.
CC, The lower additaments of the Lambdall suture on either side.
D, the fourth hole of the wedge bone in the outside of the orbe of the eye.
F, A part of the fourth proper Suture.
H, the great hole of the *occipitium* made for the spinall marrow.
K, A part of the bone called *Synclipter*.
LL, A part of the fore-head bone.

MM, The lower part of the nowle bone. *N*, A rift or cleft of the wedge bone which is common to the bones of the temple, drawne on the left side from *v*, to *o*. *OO*, The wedge bone. *P*, His foure processe marked 2, 3, 4, 5. *AR*, The first hole of the wedgebone at the bottome of the throat. *A*, the seuenth hole of the same at *R*. *T*, The first bone of the vpper iaw. *SA*, The fourth. *π*, The fift, where the Cutter betwixt *e*, and *π*, hath not well expressed the Suture. *TT*, The bones of the Temples on either side. *V*, The fourth hole of the bones of the temple made for the hearing. *z*, The bridge or partition of the nose. *X*, The first hole of the temple bone in his Basis. *YY*, The yoke bone. *aa*, The anterior part of the fourth proper Suture. *b*, The lower part of the fift proper oblique Suture. *c*, The lower part of the bridge of the nose which is like a Coulter where 3, is placed. *d*, The vpper part of the second common Suture. *f*, The First externall Suture of the vpper iaw in the Cheeke. *g*, The first common Suture in the side of the brow. *h*, The cavity of the Temples whereto the lower iaw is articulated. *i*, The Appendix of the Temple bone called *Stylodes*. *k*, The mammillary proceffe of the same Temples. *ll*, the knob of the nowle bone. *mm*, the 6. proper oblique Suture of the scull. *nn*, the seauenth transuerse Suture. *op*, A Line beginning from the last named Suture which climbeth by the Temples, and is more like a diuision then a line. *qq*, the lower part of the second common Suture of the scull in the hollownesse of the nose. *r*, the line of the hole of hearing. *sa*, the stony Bones. *sv*, the 5. externall transuerse suture of the vpper iaw. *Xy*, the 7. externall right Suture. *ab*, A Bastard Suture of the vpper iaw in the palate. *γ*, the hole of the eare. *δ*, the fift hole of the temples neere vnto his proceffe where *r*, should be blotted out. *B*, A hole of the bone which is not alwayes found. *E*, the second hole of the nowle bone made for the first coniugation of the sinnewes, and for the iugular veine and artery. *H*, the First hole of the *Occipitium* or nowle nose. *μ*, two holes in the marrow. *3*, the third hole or the outgate of the seauenth coniugation. *αα*, two holes of the bone for the passage of the palat which is accounted the fourth of the wedge-bone. *ξ*, Fiue holes in the basis of the wedge-bone. *v*, the hole of the fourth bone of the vpper iaw in the palate. Note that *MF*, at the right side pointeth out the cavity which the yoke bone maketh for the passage of the temporal Muscles.

throttle, the gullet and the stomacke. This Membrane although it compasse the whole circumference of the mouth and the parts conteyned in the chops, yet is it one and continuall, and of one and the same substance, but not alwayes of a like thicknesse. For in the Nostrils it is thinner, but in that part which is vnder the spongy bones it is thicker and full of small holes, through which the thicker Excrements of the Braine do passe: which excrements as they descend doe part of them passe into the mouth through those hoales which are made out of the nosethrills thereinto; part yssueth at the Nose, yea, and sometimes with violent hawking we fetch part out of the wayes of the Nostrils into the mouth.

Why we sneeze
when our nose
is tickled.

This Membrane is of exquisite Sense, so that if it be irritated or prouoked, Steruntation or Sneezing will follow, because of the consent it hath with the Chest whereinto it insinuateth selfe: but why were the nosethrills inuested with this Membrane? I answer, to hinder the growth of flesh in the nose which might make the nosethrills narrow, as it happeneth in the disease called *Polypus*. Againe, to make the nosethrills more slippery that the mucous excrement might more easily descend. Finally, that they might be partakers of Sense.

The vses of the
outward nose.

The vse of the outward nose is first for Respiration, that through it as through a canale or pipe the ayre might be conueyed in to be distributed, partly vward to the Braine to recreate and refresh the Animall spirit, partly downwards to the Lungs and the heart to refrigerate and coole the same. This is the first and especiall vse of the outward nose: for although we respire also by the mouth, yet was not the mouth created for Respiration, because if the holes of the spongy bones or the nosethrills bee obstructed (so that when wee sleepe we draw in our breath by our mouths) the tongue becomes rough and the mouth dry (sometimes also it growes bitter) that when we wake we can scarce swallow our spittle. Hence it is, that Nature prouided the nose like a couer to defend the holes that go out of the nostrils into the mouth through which we breath when we are asleepe and our mouths shut vp.

That the
mouth was
not made to
breath by.

The seconk vse of the outward nose is to serue the sense of Smelling. *Hippocrates de Carn.* faith: The moyst Braine smelleth the odors of dry things, drawing them together with the ayre through gristly bodies. For the nose leadeth the ayre, informed, as it were, with the formes of odors through the holes of the Spongie bone to the Mammillary processes as vnto the principall organs of smelling, from whence it is conueyed to the braine: for if a mans nose be cut off at the roote, eyther he cannot smell at all, or at least but imperfectly.

Galen.

The third vse is, that through it the excrements of the Braine might distill, or by a vehement efflation be blowne out. And these two last vses *Galen* expresth excellently in the sixt Chapter of his 8. Booke *de usu partium* on this manner. *From within outward are the Excrements of the Braine deriued through the Nostrils. From without inward are the Obiects of the smelling Faculty transported this way. One Instrument serueth these two turnes of Nature; one of which is necessary for the preservation of Life, the other for our better life.*

Finally, the Nose serueth to forme the voyce, and addeth a great beauty to the Face.

CHAP. XXVIII.

Of the Inward Nose and the manner of Smelling.

That the Nose is the Instrument of Smelling all men will confesse, but because it is compounded of many and diuers parts, it is a great question to which particle among all the rest the *Action of Smelling* is to be attributed. Of these wee haue already examined those parts which make the outward Nose, it remaineth therefore that we prosecute our History in the parts of the Inward Nose.

The inward
nose made of
two parts.

The spongy
bone.

The Inward Nose therefore consisteth of two parts, the bone called *Ethmoides* or rather the spongy bone, and the Mammillary processes. The Spongy bone is situated partly in the top of the Nostrils, partly within the Scull. It is a couering of the Mammillary processes thrilled full of holes or rare and Spongy, through which perforations the ayre is immediately conueyed to the Braine for respiration, and vapors for the distinction of odours: that way also the whole source of the excrements is conducted.

The Mammillary processes which make the other part of the inward nose do proceede out

out of the Braine and haue their habitation within the Scull about the cavity or bosome of the spongy bone. Of this spongy Bone we haue sayd somewhat already in the 6. Chapter of the 7. Booke, and shall speake afterward more at large, and concerning the *Mammillary* processes we haue intreated of them sufficiently in the 16. Chapter of the 7. Book, whither we referre the Reader, and proceede to discouer vnto you the manner of Smelling. And because I would not haue you think that *Hippocrates* was ignorant from whence this Sense came and where it was accomplished, you shall giue me leaue to relate vnto you a short passage or twaine out of his workes. The first in his Booke *de Carnibus*, where he speaketh to this purpose.

2. passages out
of Hippocrates.

The Braine hath in it a Faculty of Smelling though it be moist, and draweth through gristly bodies which are dry, together with the ayre the odours of dry things. For the Braine reacheth euen vnto the cavity of the Nose, hauing no bone in his way but onely a soft gristle like a sponge, which you can call neither a Bone nor Flesh. If therefore the cavity of the Nostrils be dry, then doeth the brain better and more exquisitely perceiue the odours of dry bodies. For it cannot smell water because it is moister then the braine, vnlesse it be corrupted. In like manner when the Nostrils are moist wee cannot smell, because at such times the braine doth not draw the Ayre into it selfe.

Againe in his Booke *de locis in Homine*. There is no passage tending vnto the Nose (hee meaneth the Sense of Smelling) but a loose and spongy substance, and that is the reason why we heare further then we smell, for if the Sense be far from the Sense it is dispersed before it attaine thereto.

Galen more distinctly (as being better acquainted with Anatomy) on this manner in a particular discourse of this subiect. *The Braine sendeth out two sprouts long and hollow, taking their originall from the foreward ventricles and determining at that part of the Scull where the Nose beginneth, where are placed certaine Bones called Ossa Ethmoidea, that is, like a Syue or Searce. But we returne to the manner of Smelling.*

According to *Aristotle* there are three things required to euery Sense; an Obiect, a Medium and an Instrument or Organ.

3. things re-
quired to sense
The Obiect.

The Obiect here are odours or vapours of a fire Nature.

But what an odour is, is not so well knowne as what a Sound or a Light, or a colour is: wherefore in men this Sense is the dullest of all the rest, as *Aristotle* sayeth in his Booke *de Sensu & sensibili*, and many creatures Smell a great deale more exquisitely then we; we touch more exquisitely then any other creature, at least that Sense in vs is most perfect. Whence it is that a man receiueh no Smell without pleasure or discontentment, because the Instrument is not perfect.

The Sense of Smelling is the middle Sense, for there are Fiue Senses, two that worke by contact, as the Touch and the Taste; and two that apprehend their obiects by the interposition of an other, as Sight and Hearing.

Smelling the
middle sense.

Now because Odors are not so manifest (saith *Aristotle* in the 9. Chap. of his second book *de Anima*) as Sapours (for our Language vseth the word Saviour promiscuously in both these Sences) therefore it is that the names of Odors are taken by a similitude from saviors, so that some odors are called sweete, as that of Saffron and Honny; others sharpe as Tyme and such like; there is also a fowre Odour, an acute and a fatte. Wherefore *Galen* in the 22. Chap. of his 4. Booke *de simpli. medic.* teacheth vs that Odors do moue the Taste as saviors doe; for if our meates be corrupted the Taste is able to find the vnpleasing odour, and wee throw them away. Yea almost in euery thing the smel and the Taste haue a mutual consent; wee say almost, because in those things that are most fragrant and sweete smelling as is a Rose, the Smelling and the Taste doe much differ. For the smel is delighted with the Odor of the Rose, but the savor thereof disturbeth the Taste. But as the Hearing is audible and inaudible, the Sight visible and inuisible, so also the Smelling is odorable (for it is no treason to Coyne words in so vnouth a tract of speech) or inodorable. That is inodorable, eyther that hath not nor can haue any odor, or that which hath but a little odor, or that which hath an euill or offensive odor, and so much of the Obiect.

Whence odors
haue their
names.

The consent
betweene the
smell and the
taste

The Medium by which we Smell is the Ayre or Water. For those creatures which liue in the water whether they haue blood or no blood, are yet apprehensie of odours, as also those that liue in the Aire. For Fishes and Snayles and those we call *insecta*, do smell their nourishment a farre off, and approach thereupon vnto it, because of the Alimentary species of the odour, as Bees will flock to Honny, and so in the like.

The medium
of the smell.

But man neuer smelleth but when hee draweth in his breath, for if hee hould his breath,

How a man
smelleth.

That vnbloo-
dy creatures
do smell.

breath, though you put odoriferous things into his Nose he cannot smell them; the reason is, because the instrument of his Smell is not placed in the superficies of the coate of his nostrils, but farre within, to which there are certaine perforations that leade. Againe, in inspiration the instruments themselues are dilated, which if they were not dilated the ayre could not passe through the pores nor ascend vnto the processes and so vnto the ventricles of the Braine. Other creatures, euen those that are without blood do smell, though they do not respire, and they smell because they are able to receiue and *perceiue* odours. And that they do *perceiue* odors, it is manifest, because they are stifled with those odors, where-by men are also stifled. For saith *Aristotle* in his Booke *de sensu & sensibili*, as men get a stuffing in their heads, yea are sometimes suffocated with the steame of Charcoales, so many insectile creatures are driuen away with the smell or vapour of Brimstone or other Bituminous matter, because they are annoyed, yea killed by them.

Hence it followeth that the instrument of smelling in men differeth from the instrument of smelling in such creatures, as a mans eye differs from the eyes of those creatures which haue hard eyes. For those creatures that haue soft eyes haue also eye-lids to cover them, which lids, if they do not moue and open they cannot see, but those that haue hard eyes haue no lids at all, nor any thing proportionable thereto, but they see immediately that which is to be seene.

A difference of
this instrument.

In like manner saith the Philosopher, in those creatures which doe not respire the chiefe instrument or Organ of smelling hath not couer at all no more then their eyes haue. But those creatures which draw in ayre haue their organs of sight and hearing couered; yet because in their breathing their veines and passages are distended, the instrument is vncovered, or it may be their breath remooueth the couering away, but when they doe not respire they cannot smell, which is all otherwise in those creatures that doe not respire. Hence it is that those creatures that doe respire cannot smell when they are vnder water, for they must respire when they smell; but in the water they cannot respire.

Aristotles conceit
of the couers
refuted by
Galen.

This conceit of *Aristotles* concerning the couers of the holes of the nose, *Galen* in his booke *de instrumento olfactus* refuteth. For saith he, it is an vncertaine thing which cannot be demonstrated nor made eident, that we should assuredly beleue it to be true: beside, saith *Galen*, it is of no vse.

But let vs grant that in the bottome of the Nose there is a couer which is opened by inspiration, that the way may be made open for the ayre and vapors to passe in; and that when the inspiration is ended, it againe closeth: It must needs be that the motion of this couer (saith *Galen*) must be Animall or Naturall or Violent.

That it is Animall or voluntary no man will say, because there is no neede of a couer or valve for Animall motion; beside Animall motion followeth our wills, but this couer is neuer opened sauing when we draw our breath. Againe, the instrument of Animall motion is a muscle, but in the top of the nose on the inside there are no muscles.

Neither is this motion Naturall as is the motion of the valves of the heart, because the motion of the Heart is perpetuall and not at our command.

An instance
out of *Galen*.

Violent we cannot say it is, for then (saith *Galen*) when the Ayre rusheth forcibly in, the couers should be opened euen without attraction or drawing of our breath; but this we are able to disproue. For put a man into a chamber fulfilled with some strong odour, and moue the Ayre neuer so vehemently, or leade the smell into his nostrils with a reede (for so doubtlesse those couers if there were any would be refferated) yet he will not sent the smell at all, vnlesse he draw in his breath. Concerning this matter, he that desireth further satisfaction, let him reade *Galen* diligently. We will proceede vnto the third thing required to sensation, which is the Instrument.

The instru-
ment.

Concerning the instrument of Smelling we haue before related the opinion of *Hippocrates*, of *Aristotle* answered of *Galen*, and also by *Galen* himselfe. But the truth is, saith *Archangelus*, that all the ancients were ignorant of this Mystery.

Amongst the latter Anatomists *Varolius* hath well described it, so hath our Author *Ban-
bine*, you shall heare both their conceits.

Varolius.

Varolius hath it thus: Two nervous productions proceed out of the very middest of the Braine, wrought as it were out of the substance thereof; these productions shooting forward doe determine at the top of the nostrils and make the chiefe instrument of Smelling, to which place when the odoriferous exhalations doe attaine, the instrument *perceiveth* the species of the odor without any matter, and into this species is changed; the exhalation is dispersed or extended through the substance of the Braine.

BAN-

Bauhine hath it thus : As the Eye is the instrument of the Sight, and the Eare of hearing, both of them compounded of many particles : so the instrument of the Smell is the Nose. But because in every sense there is one principall part, it is a great question which is here the principall instrument by which the faculty taketh knowledge of the proper objects of this sense. Some thinke it is the Nose, because if we shut our Nose and draw in breath through the Mouth we doe not smell at all, but if we draw our breath through the Nose, the odour presently striketh the sense. But because there are some creatures that smell without Noses, it followeth that the nose is not the principall Organe but helpeth the perfection of the sense, and is an assistant onely to the principall organe. We must therefore finde out some other part, and that in the Nose or neere vnto it.

Bauhine.

The principall instrument.

Not the Nose.

Galen.
Not the bone.

Not the membrane of the Nose.

Not the palat.

Not the Spongy bone.

But the mammillary processes.

Their nature.

Archam. conceit of Nerves of Smelling.

Bauhine.

Odors consist in exhalation.

We

The Bone it cannot be, saith *Galen* in his Booke *de Instrumento olfactus*, because bones are insensible every way, much lesse can they distinguish of smells. It is not the coate or membrane of the nose that discerneth odours; for though you fill the nose with odoriferous things, yet we do not smell before we draw our breath. Again this coate is very like that membrane that inuesteth the vtmost part of the head, which membrane partaketh not of this sense, and therefore not this coate of the nose. It is not the coate of the Palate, of the Chops, or the Rough Arterie; for if you stop your nostrils and draw your breath through your mouth you shall not smell at all or freely any sense of an odour, neyther about the Pallat, or the Chops, or the Rough Artery. Wherefore the nose is the way, or the pathe or walke of odoriferous things, although to say truth it was ordained rather for Respiration, saith *Galen*, then to smell with.

The body therefore that perceiueh or apprehendeth odours is placed higher, and that is eyther the Spongy bone or the Mammillarie processes. Not the Spongy bone because, as is saide, bones are insensible together. It remaineth therefore that it must bee those processes which because they are somewhat like the nipples of a Dugge are called *Mammillares*, which proceeding out of the Basis of the Braine are by the *Pia mater* (saith *Archangelus*) ioyned to the braine and reposed in the vpper part of the Spongy bone called also *Ethmoides* (for wee will confound them) and because they are two, they are distinguished or separated by a production of the same bone carrying the Figure of a Spurrowell.

They are much of the nature of Nerves, as is before shewed in the 16. Chapter of the seauenth Booke, and therefore are best able (saith *Laurentius*) to discern of the qualities they receyue: yea (saith *Archangelus*) they seeme to haue their originall from Nerves of Smelling which do degenerate into them. For from the backe part of the marrow of the Braine at the fourth Ventricle doth the Odoratorie Nerve arise vnder the Optickes, and pacing forward are thrust into the Mammillarie processes betwixt the Braine and the Wedge bone. And these Nerves of Smelling (saith hee) were made as canales or pipes through which the Facultie of Smelling (residing in the Animall spirit drawne out of the fourth Ventricle) might be transported vnto the Mammillarie processe or the organes of Smelling; as the Faculty of Seeing through the Opticke nerves is transported vnto the eyes. The originall of these Nerves was vnkowne to *Vesalius*, *Columbus* and the rest, because haply they vsed to Dissect onely putrid or stale heades. But we returne vnto *Bauhine*.

These Mammillary processes (hauing a peculiar Nature, Figure and Composition of their owne) are esteemed to be the principall organs of smelling, especially because there is no part in the nose which can so easily be altered by odours as these: for being full of spirits they do soone receyue the species of odours. For whereas odours do consist in a kinde of exhalation (which is manifest because odoriferous things doe onely so farre forth smell as they exhale; whence it is that in Summer the scents of things are more fresh and fragrant then in Winter) and exhalations are naturally dry, it was fit that the organe of Smelling should proceede from a moyst principle, that by reason of the contrariety betweene the Object and the Organe which is necessary in all actions, the instrument might suffer and be mooued by the exhalation. And because the exhalation when it was come vnto that place might better bee dilated or extended, this instrument dooth not arise from the Spinall Marrow, nor from out of any part compassed or constrained within narrow limits, but out of the very middest of the Braine where they are wrought out of the substance thereof, and thence produced forward determine in the top of the nose, and so become the Organes of Smelling.

A briefe colle-
ction of the
maner of smell-
ling.

Wee conclude therefore that the Smell is made after this manner. The Ayre altered with Odours or by an aiery exhalation of odoriferous things is received by the Nose, which like a Chymney is broad below and narrow above; but because the proper motion of the exhalation is but weake that it cannot make a sufficient impression; it is increased by traction. Wherefore when the mouth is shut and the Chest dilated (for vnlesse the Chest be dilated we can smell nothing) the exhalation that is disperfed through the ayre is by inspiration drawne into the nofethrils: and because out of them there are two holes which go vnto the pallar, the greatest part of that ayre so drawn in entred into the lungs but without any sense of odours; the rest ascendeth vpward to the instruments of Smelling, but it is altered in the spongy bones euen as in the cauities of the eares the auditory ayre is prepared. This ayre thus altered in the Labyrinths of the spongy bones together with the species or forme of the odor passeth thorough the holes of that *Sine* into the *Mammillary processes*, or by them it is received and so conueyed to the common Sense which is in the Braine that it may iudge thereof. For the Braine is the common instrument of Sensation or the organe of all the senses, or it is the instrument by which the *Sensatiue Soule* perceiueth all sensible qualities, yea distinguisheth and iudgeth of them. And thus much of the vpper part of the Face, wherein three Senses are situated, of which we haue intreated.

CHAP. XXIX.

Of the Parts of the Face which are betwixt the Nose, the Eares and the Chinne.

The particular
parts, with
their names.

He parts of the Face which are onely in men and vnder the eyes betweene the nose and the eares reach as farre as the chin, the Ancients called in Greeke *μῆλας*, in Latine *Gena*, because in them haire is generated. We call them the cheeks. They are diuided into an vpper part and a lower. The vpper is next vnder the Eyes, a little rising betweene the nose and the Eares and for the most part is red, in which place *Plinie* supposeth that modesty or shamefastnesse hath her seate, because that part blusseth in those that are modest. *Hippocrates* called *ἡ κυκλὸς προσώπου*, the circle of the Face, & *Πόλλυξ* *μῆλον* the Apple of the Face, because in forme and colour it is not vnlike an apple, besides their color flourisheth most in the Summer of our age.

The lower part is looser, and is all that which is without the closing of the two Iawes, reaching almost all along betweene the chin and the eyes: when your mouth is open you may raise it vp with your finger on the inside, or make it shut when you fill your mouth with Ayre, not suffering it to go into your Lungs or out of your mouth. This is called in Greeke *γυῖος*, in Latin *Bucca* the Puffe of the Cheeke; That part which is betwixt the nofethrils and the vpper lip is called *Μυσταξ*. The cavity which parteth the vpper lippe in two which is an impression therein like a valley, is called in Greeke *φίλτρον*, as it were *amiable or louchly*.

Archangelus

The Lips are cald *Labra* by *Cicero*, by others *Labia* a lambendo of licking, for saith *Archangelus*, men licke with their lips, though other creatures, as Dogs and Cats and Oxen licke with their tongues. They are two, one vpper another lower, and are nothing else but Musculous extremities of the mouth. *Aristotle* in the 11. Chap. of his first Booke *de Historia Animal.* calleth them *χείλα* because they occupy the very mouth. *Homer* also calleth them *χείλα*, and *Lycophron* in that prouerbe vsed I thinke in all Languages:

A prouerbe out
of *Lycophron*.

πολλὰ χείλες καὶ δευτέρῳ πόλιν
μέσω κυλίσσει μοῖρα παμμήτωρ σφολόν,

Great Destinie twixt the Lippe and the lippe,
Caufeth strange chances often to slippe.

The vtmost and prominent parts of the lippes are called *προχίμα* *prolabra* by *Ruffus*, and those parts that meete and looke redder then the rest because of the affluence of blood are called *πρόσθια* by *Pollux* and *Ruffus*. The hole which the two lips make when they are diuided is called *στόμα*, Or the mouth. Finally, the lower part of the Face vnder the neather lip which groweth sharpe is called *γένιον* by *Xenophon*, by *Cicero mentum à memorando* because it should seeme there is some vse of it when wee desire to remember any thing. No creature (sayeth *Plinie*) hath a Chin but man, which if it be round (according to *Pythagoras*) is a signe of an effeminate minde. The doke or dimple in the middest of the chin and

and a great ornament too, is called *ρύμφη* the Nymph; the very sharp poynt of the chinne, bearing out in the lower Iaw is called *ἔξυγος*; the flesh vnder the Chinne is called *λευχασία* in Latine *Buccula*, we call it a double Chinne. To conclude, the hayres that breake out in the Cheeks, the Lips and the Chinne make the Beard, of all which parts wee might discourse at large out of our Authors, but that we haste to that which is more profitable.

CHAP. XXX.

Of the Mouth, Palate and Vvula.

THat which is in Greeke called *στόμα*, in Latin *Os*, we call the *Mouth*, comprehending vnder that appellation not only the Cleft which is made by opening of the Lips, but also al that voyde cavity which is betwixt the lips and the roots of the chops, which are called *Fances*. It is situated in the fore and middle part of the Face, that the hands might equally reach the meate on either side vnto it.

The mouth.

It is also immediately vnder the Nostrils, that not onely the Savors or Tastes of our meates might bee offered to the Mouth, but the Sauours & Smels or Odours to the Nose-thrils. For it is fit both the Sences should iudge of that we put into our bellies.

The reason of the situation.

The parts of the mouth are of two sorts: some are those whereof the Mouth is made, others such as are containd within the Mouth. The parts whereof the Mouth is made are of two sorts, some fleshy, others bony. The fleshy parts are the Lips; the Muscles of the Pusse of the Cheeks, of the Lips and of the lower Iaw. For on the foreside the Mouth is compassed with the Lips, as well to shut vp the Mouth when we would, as also the better to sap liquid things; on each side are the Pusses of the Cheeke swelling out. These parts are couered with the Skinne hauing Fatte vnder it, which Skinne in the middest is flitte ouerthwart like the Eye-lids to giue way for the receiuing of Aliment.

The parts of the mouth

The fleshy.

The Bones are the vpper and the neather Iawes, with the Teeth fixed into them both. All these parts as also the whole inward capacity of the Mouth is compassed with a thick membrane which in the palate is somewhat rugous, spreadeth ouer the Gummes, couereth the vpper part of the Lips, and being reduplicated maketh the *Vvula*.

The bones.

The palate.

The chiefe vse of the mouth is double; first to giue way for the assumption of meates and drinckes, and that in the mouth they might be Tasted. For the Taste is apprehensue of that quality of the meate which is fit for our nourishment, wherefore in the very ingresse of the mouth is the Tounge placed which is the proper instrument of the Taste, that nothing may be admitted into the mouth which doth not make his quality manifest by the contaction of the Tounge: againe to breake the Aliment and to shred and mingle it before it be swallowed, that it may go prepared into the stomacke.

The chiefe vses of the mouth.

The second principall vse of the mouth is for Respiration, that when the Nose is stopped the aire may yet be transported, some of it vpward to the top of the nostrils, some of it downward to the Longues, for the nourishment and expurgation of the vitall spirits: especially for the framing of the voice, for we speake out of our mouths.

The secundary or lesse principall vse of the mouth is, that thorough it by hauking wee might auoide the excrements of the head, by Coughing the excrements of the Chest and the Longues, & sometimes also by Vomiting those of the Stomacke.

The secondary vses of the mouth.

The Muscles common to the Pusse of the Cheekes and the Lippes are foure, two on each side. The one called *Quadratus* or the square muscle, the other *Buccinator* or the Trumpeter; and these muscles beside the vses they haue in beasts do in men helpe the Speech, especially the Sounding of a Trumpet or winding of a Horne or Cornet.

The common muscles.

The lips which couer the mouth are two; one aboue, another below, whose substance saith *Galen* in his 4. Booke de *Anatom. Administrat.* and the third Chapter, is fleshy, fungous and moouable, and that after an vncouth mannner: for the Skin and the Muscles are throughout exactly mingled together, so that *Galen* in the 11. Booke de *usu partium* and the 15. Chapter, calleth the conformation of their substance a *Musculous Skinne*, or a skinny Muscle.

The lips.

And as without they are couered with the Skin, so on the inside they are inuested with a membrane common to the stomacke and the mouth: whence it is that in those that are about to vomit the lower lip is often seene to tremble. These Lippes all creatures haue to eat and drinke with; but men make farther vse of them to helpe their speech, to auoide their

their

Table 13. Figure 1. Sheweth the muscles of the Fore-head, the Eye-lids, and the Cheeks.
Figure 2. sheweth the muscles of the Nose, Lips, the lower law and of the bone Hyois.

TABVLA XIII.

FIG. I.

FIG. II.

μ 2, the insertion of this muscle into the lower jaw. ν 2, A small nerue running to the forehead out of the orbe of the eyes.
 π 2, A nerue propagated to the face. ρ 2, two beginnings of the seventh muscle of the head. τ 2, His insertion into the Mammillary proesse. υ 2, the clauicle or the collar-bone. ϕ 2, A place where the vessels attayning to the head and the nerues of the arme do passe through.

A 1, 2, The muscle of the fore-head and the right fibres thereof.

B 1, 2, The temporall muscle.

$\alpha\beta\gamma$ 2, His semicircular originall.

CE 1, The first muscle of the Eye-lid compassing the whole lid.

FD, 1. The third muscle of the wing of the nose which endeth into the vpper lip.

GH 1, The muscle of the vpper lip.

G 2, The place of the yoke bone without flesh.

I 1, the broad Mouse-muscle stretched ouer the cheeks and all the lower parts.

δ 1, 2, the circumscription or circumference of this muscle.

I 1, the yoke-bone.

I 2, the grinding muscle or the second muscle of the Jaw.

The forward K, in the second figure sheweth the higher gristle of the nose.

L 2, the wing of the nose.

M 2, A muscle forming the cheeks.

N 2, the muscle of the lower lip.

O 2, A part of the fift muscle of the lower iaw called *Diagastri-*
cus, that is, double bellied:

P 2, the bone *hyois* is set in this place.

QR 2, the first muscle of the bone *hyois* growing to the Rough artery.

S 2, the second muscle of the bone *hyois* vnder the chin.

The lower T, in the second figure sheweth the third muscle of the bone *hyois* stretched to the iaw: the vpper T, in the second figure sheweth the insertion of the head.

VV 2, two venters of the fourth muscle of the bone *Hyois*.

the backward K, (put in stead of X) sheweth the seventh muscle of the head and his insertion at the vpper T.

λ 1 2, the originall of the grinding muscle from the yoke-bone.

their spittle, and moreover they defend the Teeth from the coldnesse of the ayre, and are a great beauty to the Face.

The proper
muscles of the
Lips.

For the performance of all these offices they stood in need of Muscles, some of which are common with them and the Puffe of the Cheeke, of which we haue made mention before: others are proper to the Lips onely, and they are fixe; two on eyther side belonging to the vpper Lip, and one on eyther side belonging to the neather.

The lawes:

The lawes are two. The vpper which in men is mouable, and the lower which is moued voluntarily with a double kinde of motion; one simple another compound: the simple motions are fixe, vpperward, downward, to the right hand and to the left, forward and backward.

The compound motion is made of that which is to the right hand and to the left, and that which is forward and backward: and by this motion the law is *circumduced* or led about. It is moued vpperward by the muscle called *Temporalis*: downward by *Diagastri-*
cus, to the right hand and the left by *Masseterius primus*: backward by *Masseterius alter*: forward by the fift paire: of all which as also of the common Muscles we shall intreate in the book of Muscles and of the Bones.

The parts contained in the mouth are diuers besides the teeth and the bone *Hyois*, of which we shall intreate among the bones. These are the Gums, the Palat, the *Vuula*, the Almonds, the Tongue, the Larynx or throtle, the Muscles of these parts, and the beginning

ning of the Gullet.

The Gummes are made of flesh, which *Auerhoes* saith is glandulous; the *Gracians* call it *ἰσχυρὸν τριβύλιον* which signifieth to inuolue: it is hard, saith *Baubine*, and immouable that so the teeth might be better fastened in their sockets, so hard the gums are that such as haue lost their teeth are able to breake their meate sometimes with them.

The Palate is the vpper part of the mouth, wherefore the ancients, as *Hippocrates*, and *Galen* from him call it *ὑπερώα*; *Aristotle* *ὑπαράς*, as it were *Cælum oris*. The Latines call it *Palatum*, because it is fenced in with teeth, as it were with Pales, as if one should say *Paled in* [tab. 13. fig. 4.*] The extension of the Palate is from the backpart of the mouth to the teeth and is hollow like an Arch, but the rooffe is not too high, hence wee call it commonly the rooffe of the mouth, but those whose heads are acuminated or like a Sugar loafe, haue high roofes or palates, as *Hippocrates* obserued in the first section of the sixth Booke *Epidemion*. This is the soale or basis of the Braine established by the wedge bone, which therefore *Galen* calleth the bone of the palate, though, saith he in his 19. Chapter of his 11. Booke *de usu partium*, it scarce touch the palate.

It is made partly of bony substance and partly of fleshy; the bone is hard and fast, lest it should rot by the confluence of excrements vnto it, as wee see it doth in the French disease. This bone is double on both sides, for it is compounded of the 4. bone of the vpper iaw into

which the teeth are fastened, and the sixth bone which maketh the backward amplitude therof. It is also diuided in the middest by a Suture, in the end whereof are two holes through which the braine is purged into the mouth, and so there becomes a great society betweene the nofethrilles and the palate. Through these holes when we hold our mouths close we may expire and inspire, breathe in and out, and when the wayes of the nostrils are obstructed, the excrements gathered together in the ventricles of the Braine are this way deriued into the mouth. But the backward halfe of the palate which endeth into the *Fauces* or chops, and is stretched out from one side to another, consisteth of a thicke and glandulous flesh.

It is inuested with a thicke coate arising out of the *dura mater*, which hauing gotten out of the skull is enlarged, becommeth thicker and compasseth the whole mouth and palate on the inside, yea it is common also with the gullet and the stomacke. Hence cometh the great consent betweene the Palate and stomacke, for it was fit that the coate of the palate should haue the sense of Tasting, that it might take the assay vnto the stomack. Wherefore the sense of it is more exquisite, as receiuing into his back part certaine small nerues of the fourth coniugation, which coniugation is also distributed vnto the palate.

This is also the cause why wee cannot euacuate the head with Masticatorie Medicines, but the stomacke also will bee euacuated by the palate: now the head is euacuated by the palate, because from the head certaine hayry threds of veines doe descend vnto the palate.

This coate of the palate in some places is rugous and rugged, which *Plinie* calleth *Crenas*, that the meate might be better mitted. It is also hollow or concauous, that the voyce might be better formed when the ayre is reuerberated; in this concauity also as in a bosome the ayre we draw in is warmed, that it should not descend cold vnto the vitall parts to offend them.

The Vuula hath many names: It is cald *Gargareon*, or *Curgulio* by *Hippoc.* by *Aristotle* *κίον*, but the proper name is *Gargareon*; *κίον* and *σαβύλη*, that is *vuula*, are the names of it when it is ill affected. The name *Gargareon* is a made word of the sound we make when we gargle, or else from Gargles which we vse in the diseases of this part. It is called also *Columella* & *pletrum*. It is a particle of the mouth or a certaine proceffe saith *Ruffus*, hanging directly downeward (from the inward part of the palate [table 13. figure 4. E] neare the holes of the nostrils which looke into the backpart of the mouth) into the capacity of the mouth betweene the Almonds [F F] aboue the slit of the larynx or throtle [E] as will easily appeare if a man open his mouth wide and presse his tongue downeward.

The substance of it is glandulous, red, and fungous hanging downe from the middest of the glandulous part of the palate. Some thinke it is made of the coate of the palate reduplicated at the end of the mouth and a litle elongated, this was *Columbus* his conceit.

If it be diseased by a fall of humors it is no more called *Gargareon* but *κίον* and *κίον* and *σαβύλη* and *κίον* and *κίον* and *κίον*.

For if it grow equally thicke from the Basis to the end, and fall lowe, become redde,

It is called also *αν-νίς*, and therefore *Galen* calleth them in whome it is ill affected *κίονος*.

The vse of the *Vuula*.

The vse of it is to temperate and moderate the coldnesse of the ayre we breath in, that it fall not suddenly vpon the Longues, and so the bloud (saith *Aphrodisius*) become condensed and thickned by the Inspiration of cold ayre, whereby the motion of the Longues might be made slower; whence it would follow that vpon so great a contention in the motion, the vessels might be broken and a consumption follow.

Another.

Another vse of it is to moderate and Tune the voyce, for only Men and a few Birds haue it: hereupon it is called *plectrum vocis* the quill of the Voyce. For hanging in the cavity of the Palate betwixt the *Larynx* and the cavity of the nostrils it maketh a repercussion of the ayre as it yssueth out of the Throttle. Hence also it is that it helpeth pronounciation very much as *Columbus* saith; who also auoucheth that if it be eaten away by the French disease, or cut off when it is inflamed, the voyce will neuer be shrill or cleere after.

Columbus.

Gainfaide by *Falopius*.

This *Falopius* gain-faith vpon his owne manifold experience, and *Bambine* telleth a Story of a Marchant whose *Vuula* (for I know no other name for it in English) had been some yeares since consumed by a defluxion of sharpe humors, who yet found no decay or fault in his speach to follow vpon it, marry otherwise he grew *Tabid*, that is, into a consumption. Wherfore, saith he, we conceiue that those that haue their voyces impayred by the French disease, doe not only loose their *Vuulas*, but the Vicers eat away a great part of that glandulous body which is betwixt the Bone and the coate of the Palate, or else the bone of the Palate and the membrane is perforated. The like conceit also hath *Falopius*.

A third vse.

Some adde a third vse of the *Vuula* to purge the Ayre, for it licketh vp the dust which otherwise together with the ayre would descend into the Longues. But *Vesalius* doeth not approue of this vse, and he rendereth this reason, because other creatures that drawe their breathes nearer the earth (and so more in danger of dust then men) haue not yet this *Vuula*.

Varolius his vse of the *Vuula*.

Finally (for I will not insist vpon euery mans conceit) *Varolius* concerning the vse of the *Vuula* expresth himselfe on such a manner.

The *Vuula* receiueh the excrement of the braine conuayed vnto the Phlegmaticke glandule through the Tunnell; this excrement it imparteth vnto the Palat, the Tongue and other instruments of the Voice to moysten them, that which is ouerplus is cast out by spitting and hauking. For as in a Flute the Sound will not be shrill and cleare vnlesse it bee wet, so it is in the voyce of a man: and therefore Nature placed the *Vuula* which receiueh the moysture of the braine directly ouer the slit of the Throttle or *Larynx*, that it together with the rough Artery might better be moystined.

CHAP. XXXI.

Of the end of the Month called Fauces or the Chops, and their Glandules.

The extent of the word.

ALTHOUGH the word *Fauces* or the Chops, doe among some Anatomists, *Vesalius* and *Laurentius* especially, signifie all the capacity of the mouth; yet properly it signifieth the backward and lower part of the mouth, or that space where the ends of the Gullet and Rough Artery doe meete, and may not bee perceiued vnlesse the mouth be wide opened and the Tongue depressed. [tab.

13. fig. 4. betwixt F and I] The Grecians call it *φάρυγξ*. Yet this word *φάρυγξ* hath diuers significations: sometimes it is taken for that wee call *Fauces* or the Chops, sometimes for the *Larynx* or Throttle, because they are neare together, sometimes also for the whole Rough Artery. *Aristotle* in diuers places giueth this name to the Gullet. *Philoxenus Erixius* saith a notable Gourmandizer wished *φάρυγξ* (that is his Gullet) longer and bigger then a Cranes. Some by this word vnderstand all the glandulous bodies about the Chops. But in *Hippocrates* where we haue this word *φάρυγξ* put by it selfe, it signifieth some disease of the Chops, as their roughnesse, in the fift Aphorisme of the third Section, or their Infla-

mation as in the seventh Section of the sixth Booke *Epidem.* and the first Aphorisme. This place also is called *ισθμος* by *Galen*, and *ισθμους* by *Hippocrates* by a Metaphor, because of the narrowness of the place: for *Isthmus* signifieth properly a narrow tract of ground betwixt two Seas, and in the whole body there is no part so narrow and straight which containeth so many instruments. For in those *Fauces* are contained, first, the holes of the nostrils descending through the palate into the mouth [*Table 13. Figure 4. after E*] of which we have spoken in the Historie of the Nose; againe, the muscles of the *Fauces* or Chops, the bone *Hyoides* vnder the root of the tongue, the tongue it selfe, the *Larinx* together with the *Epiglottis* and the beginning of the gullet; beside the muscles of these parts and some of the lower iaw. Add hereto certaine propagations of the nerves of the third, sixth and seventh coniugations, the iugular veines; the sleepey Arteries, and certaine glandules of which we will intreate in the next place because they are best exhibited in the thirteenth Table.

Why it is called
Isthmus.

What parts are
contained
therein.

There are three sorts of Glandules in the region of the Chops.

The first is vnder the roots of the Eares (which *Vesalius* accounteth for the third kind) of which we will speake in the 11. Booke. The second are those they call *Tonsilla* or the Almonds, of which we will intreate in this place. The third are those (*Vesalius* calleth them the first) which grow at the roote of the *Larinx* on the sides of the rough Artery, of which we shall make mention when we come to the *Larinx*, but discourse of in the 11. Booke.

Three sorts of
glandules neere
this place.

The Almonds are commonly called *Tonsilla* [*tab. 13. fig. 4. F*] *Celsus* calleth them simply Glandules. They are situated in both sides of the Mouth at the rootes of the tongue betwixt the holes of the nostrils and the *Larinx*, or betweene the beginnings of the weazon and the gullet, on either side one, large, long, and compared to Almonds, and therefore they are commonly called the *Almonds of the throte*. The *Gracians* call them *αμυγδαλα*, because they are seated in the *Isthmus* of which we spake even now. For if you looke into the cavitie of the mouth when the lower iaw is remooued, you shall see the two holes of the nostrils and the *Vula* or *Gargareon*: the two holes like two seas, and the *Gargareon* like a narrow tract or necke of land running betweene them. By the same name of *Paristhmia* they vse also to call not onely a part of the *Fauces* or Chops, but also the inflammation thereof, yea the disease of these glandules when they are inflamed, or when they swell or are resicuated, when they hinder (saith *Paulus*) the free passage of the drinke or the breath. For their swellings seldome hinder the passage of the meate because being but lax loose bodies the weight of the meate beareth them downe before it, and by this wee commonly distinguish betweene the inflammation of the Muscles of the Tongue, which we call an *Angina* or Squinsie, and the swelling of the Almonds; for in the Squinsie wee cannot swallow any thing without great difficulty, and the more solid thing the worse; in the swelling of the Almonds we can hardly draw our breath or take downe any liquor, but solid meate will goe downe much more easily.

The almonds.

The difference
betweene the
swelling of the
almonds and
the squinsie.

Sometimes also by the word *Paristhmia* is vnderstood the inflammation onely of the coate which we saide was common to the Chops, the whole mouth and the stomacke; sometimes the inflammation of those muscles which ly next vnder the saide coate, sometimes the inflammation of the bodies which are within the *Fauces*.

Paristhmia.

They be also called *αμυγδαλα* by *Hippocrates* in his second Booke *de morbis*, because they are placed in opposition one vnto another; but this name is not giuen onely to the Glandules but also to their disease, so saith *Hippocrates* in the place before quoted; It will not bee amisse to thrust your finger into your mouth and to beare downe the *Antiades* that is, the Almonds when they are swelled. Yet some put a difference betweene *Antiades* and *Paristhmia*, for they say, that the Almonds themselues inflamed are called *Antiades*, and the inflammation of the parts about the Almonds *Paristhmia*. So saith *Celsus*, the *Gracians* call the Almonds which are hard after their inflammation *αμυγδαλα*.

Antiades.

They are couered with the common coate of the mouth and the other parts of which wee spake lately which is nervous and in many places perforated with large and ample holes, insomuch that some haue sayde it is fungous. These holes saith *Falopius*, if the glandules be a little swelled, are wont to deceiue Chyrurgions, for they take them to be Vicers, whereas indeed there are no Vicers at all; for when the glandules fall they become againe according to their wonted nature. They also receiue veines from the iugulars. Their substance is like that of the glandules, but more rare, spongy and fungous, and therefore *Hippocrates* in his fourth Booke *Epidemion* calls them *σπγγες* Sponges, because after the

How couered.

Another note
for Chyrurgi-
ons.

manner of Sponges they drinke vp humiditie, yet *Hippocrates* also calleth their tumors by the name of *σπύγαι*.

The vse of the almonds.

The vse of these Almonds is saith *Hippocrates* in his Booke *de Glandulis*, to receiue the moysture of the braine : this moysture it conuerteth into spittle, whereby all the parts within the mouth are moystened euen the Gullet-and the weazon, the Tongue also kept from drying, and made more glib and nimble. It helpeth also the Sense of Tasting, for we cannot Taste without moysture; like as in the stomacke there is no concoction or mitigation without boyling, whereof they haue experience whose Tongues are rough and dry.

CHAP. XXXII.

Of the Tongue and his Muscles.

The names.

The Tongue is called in Greeke, *λίσσα* in Latine *Lingua*, of licking, or because it is as it were tyed within the pale of the Teeth saith *Varro*. It is a notable instrument both of the Taste and of the Voyce; because in the Mouth it is placed next vnder the Palate [*tab. 13. fig. 4.1*] in the way, saith *Cicero* 2. *de Natura Deorum*, which Nature prepared for the passage of meates and drinks. The Basis of it resteth vpon the bone *Hyais* about which it is moued, and neare the *Epiglottis* it maketh an angle or corner, and from hence hangeth and walketh freely in the mouth.

The place.

It was fit (saith *Galen* in the fifth Chapter of his 8. Booke *de usu partium*) that it should be placed neare the braine as are the rest of the instruments of the Sense, because it is the principall instrument of the Taste. Wherefore Nature for the Tongues sake placed the Mouth in the Head that it might haue a den or caue or chamber to moue in, that it might bee a convenient instrument both of the Taste and of the Voyce, as also might helpe the chewing and swallowing of the meate.

The figure.

The figure of the Tongue is not alike in all Creatures, in some it is *Trifanged* as in Serpents, in others *Bi-fanged* as in Lizards; some haue two Tongues as the Sea-Calf. In Fishes it is fastned all along, in Lions and Leopards it is rough and furrowed, but in man it is somewhat long, thicke at the roote for strength, and broad that it might bee fit both for Taste and Speech. In the end it becommeth by degrees sharpe for quicker motion saith *Galen* in the 10. Chap. of the 11. Booke *de usu part.* *Archangelus* compareth it to a *Pyramis*.

The vpper and rough part called *ινγλωττις* is hollowed on either side, those they call *χρηματις* and *παρὰδρυα*.

It is soft, broad and loose or at liberty that it maybe conuayed, produced, dilated and diuersly disposed; for in those that are tongue-tyed we see a manifest defect of vtterance. We may also obserue out of *Aristotle* in the 17. Chapter of his second Booke *de part. Animalium*, that those Birds which can be taught to prattle haue broad Tongues about other birds: and the reason why brute beasts cannot deuide or articulate their voyce is because their Tongues are hard, thicke and not at liberty.

The magnitude.

The magnitude of the Tongue is not all one in all creatures, but proportionable for the kinde whereof they are. Neyther is the quantity of it all one in all men; but it is longer then broad, and broader then thicke, and also proportionable for the amplitude of the Mouth, saith *Galen* in the 10. Chapter of his 11. Booke *de usu partium*, that it might reach into euery corner and the nooke thereof, and not hinder the receiuing of meate. But it is faulty sometimes in magnitude, sometimes in the very substance together with his muscles. For if it be bigge it filleth vp the spaces of the mouth and the Chops, and then it cannot moue so deliuerly or nimbly as otherwise it would, and such men are called *blasi* and *balbutientes*, that is Lispers and Stutters, especially if (as it happeneth most what) it be also too soft or moyst. Hence it is that Infants and those children that are moyster then ordinary doe speake slower and later then others, because of the softnesse and loosenes of their Tongues and the muscles thereof, till when their heate by their age encreasing the ouer abundant moysture is consumed. The Tongue also sometimes is too short when the *Bridle* thereof is not enough cut, so then it is hindered that it cannot apply it selfe on euery side to the Mouth; or because the muscles being little it is moued too swiftly and so implicateth reciprocateh or doubleth the speech and maketh the words come hudling together.

Blas Balbi.

What children speak slowly.

If

It is tyed to the *Larynx*, to the bone *Hyois* (vpon which the rootes thereof resteth as vpon a Basis and by which it is supported) to the Chops also, and on both sides to the Almonds; below it is fastned with a ligament.

The connecti-
ons of the
tongue.

The Tongue is compounded of a proper flesh, a coate, nerues, veins, arteries, muscles and a ligament.

Whereof come
pounded.

The ligament is [tab. 14. fig. 3. 11] very strong, membranous and broad, and is vnder the middest of the body thereof.

The ligament.

The vse of this ligament is manifold: for the solidity and strength thereof listeth vp the Tongue, and not onely so but auaieth much to lill it forth. For were it not for this ligament the Tongue would bee too much gathered backward, neither when it is shot out of the mouth could it bee easily retracted or drawne in againe. Moreover, if it were on euery side free and loose, it had not bene so firmly established and fastened in his proper seate. This Ligament also receyeth the insertion, saith *Vesalius*, of the proper Muscles of the Tongue which otherwise would easile haue bene relaxed or loosened or else parted asunder. At the end of this Ligament toward the tip of the Tongue there groweth a little Chord which *Arantius* and *Laurentius* call the *Bridle* of the Tongue. For a mans Tongue in new borne infants is fastened euen vnto the end with a Tye which the Midwives do vse to teare with their Nalles, sometimes it is faine to be cut, because it is a hinderance to their speech, yea to their sucking, because it cannot lappe it selfe so well about the nipple. The tongue therefore beeing naturally nimble and voluble least it should bee alwayes importunately prating, is restrained by this Tye, as it were by a *Bridle*. Wherefore, by the helpe of the Ligament and the *Bridle* and of many Muscles working together and contracted towards their originall, the Tongue becommeth narrow and pointed, lifted vp and diuersly mooued, and withall restrained from moouing too farre on any hand.

It is invested with a coate common to it with the Mouth, the Pallate, the Gullet and the *Larynx* [tab. 14. fig. 1. A A, B B, C] least the lax and rare substance thereof should part asunder. This Coate is all very fine and thinne, that the sapor might more easly pierce through into the pulpe and substance of the tongue, into which coate as also into the flesh certaine Nerues of exquisite sense are disseminated.

The coate of
the tongue.

The substance of it is soft, loose, rare and like a Sponge that it might be the sooner moistened with the humour which carrieth the sapor in it, and so fitter to discerne of the diuersity of Tastes, for of them it is the competent iudge. Hence it is, that in diseases it is diuersly affected, for as the humor is that it imbibeth, so is the sense of the Tasting depraued, as we may see in those that are sick of the yellow Iaundise or of Agues. The flesh therefore of the Tongue is proper and peculiar to the tongue, there being none such in the whole body: toward the Basis it commeth neerer to a Glandulous substance then to a Musculous, because it is much softer and looser; yet hath it all manner of fibres, but those so intertexed and wouen together that they cannot be separated one from another which may be done in Muscles.

The substance
of the tongue.

Again, the Fibres runne through the length of the Muscles, which is not so in the Tongue; for it hath no Ligamentall Fibres to strengthen it as Muscles haue vnlesse it be a middle one which runneth vnder the tongue. Finally, no Nerues from the Braine that should giue it the power of motion do runne through the substance thereof, wherefore it cannot be called Musculous, although I know some men are of opinion that it is made of two Muscles arising out of the bone *Hyois*, and determining in the tip of the tongue seuered by a white line: some say also there are two other Muscles of which the pulp of the tongue is compounded: but if it werere made of Muscles it should onely mooue not taste, for what Muscle doth taste? We resolue therefore that the flesh of it is not Musculous.

That it is not
musculous.

At the roots of the tongue, besides the Muscles inserted thereinto, there adhereth a great quantity of hard fat.

The Fat of the
roots.

The tongue receiveth two kinds of Nerues, one soft which carrieth sense vnto it from the third and fourth coniugations, yet so that one branch is disseminated into the coate that investeth the tongue to be an instrument of *Touching*, for the Tongue is apprehensue of all the *Tactile* qualities, as cold, heate and such like. The other Nerue is sprinkled into the flesh of the tongue which is the instrument or organ of *Taste*, and by that meanes the tongue is made apprehensue of *Sapors*.

The nerues of
two kinds.

Table 14. Figure 1. and 2. sheweth the tongue cut from the bodie, and the Muscles thereof. In the first the right side of it, and in the second his Muscles some-what uncovered. Figure 3. sheweth the body of the Tongue diuided according to the length of it and his Ligament.

TABVLA XIII.

FIG. I.

FIG. II.

FIG. III.

AAA, The tongue inue-
sted with a Coate com-
mon to the mouth.

BB, A portion of the coate
compassing the mouth cut
from the mouth according
to the sides of the lower
iaw.

C, A part of the same coate
cut from the inner part of
the Palate together with
the tongue.

D, The Muscles cald *Basi-
glossi*, according to *Vesali-
us* the first, but in our ac-
count the fourth, or the
sixt of the bone *Hyois* ac-
cording to *Falopius*.

E, The Muscles cald *Cerato-
glossi*, or the second Mus-
cle according to *Vesalius*,
and in our account the fift.

F, The Muscles called *Styloglossi* or the third Muscie. G, The Muscles called *Myloglossi*, or the fourth Muscle according to *Vesalius*. H, The flesh consisting of the Glandules, or the ninth Muscle of the tongue according to *Vesalius*. II, The Ligament of the tongue. KK, LL, The Musculous substance of the tongue, and the fibres thereof.

Caution.

The other kinde of Nerves is hard, that is, Nerves of motion, to wit, the seauenth coni-
ugation, which with many surcles is disseminated into his muscles that the tongue might
be mooued with voluntary motion; and because this Nerue is placed in the lower part of
the tongue, the Chyrurgion or Midwife must be very carefull lest when they cut the *Bridle*
they do not cut the Nerue.

The veines.

It hath also two notable Veines called *Ranina*, not because they are like Frogges, but be-
cause they are of the colour of a Frogge. They yssue out of the inward branch of the exter-
nall Iugular Veines and runne vnder the tongue, as it will appeare vnto any man that listeth
it vp. These Veines in the diseases of the mouth, the heate of the *Fauces*, the Squinzie and
such like, are opened for deriuation; after the blood is euacuated and reuelled by the ope-
ning of the *Humetarie Veine* of the *Arme*.

The arteries

It hath also two large Arteries on either side one from the sleepey Arteries which ac-
company the Veines. These are allowed to the tongue to maintaine the life of it, as the
Veines were to supple it with nourishment.

The body of it

The body of the tongue although it be continuall not diuided by any partition, whereby
it becometh fitter to Taste with, to breake the meate, and to articulate the voyce; yet it
is diuided or rather scored thorough the middest with a white line, which *Hippocrates* in
Coacis first called *Apur*, that is, the *Median*, which Line runneth thorough the very middest
of the surface of the tongue diuiding it into a right side and a left, yet not as it is in Lizards
whose tongues are forked; so that the tongue (as all other the Instruments of the *Senses*)
is double, and therefore *Galen* calleth it a *Double Member*.

The

The Uses of the Tongue. Although it bee but a little Member yet it is of great vse, because it expresseth all the conceites of the minde, wherefore our wise Creator hath defended it with many Teeth, with Lips, and restrained it with a Bridle, that beeing so carefully attended it might not run before the minde, which first ought to consulte and deliberate before the Tongue pronounce any thing.

The uses of the tongue.

The vse therefore of the Tongue is eyther primary or secondary. The primarie vse is, that it might be a conuenient and fit organ or instrument both of the Sense of Tasting and of the Speech. Of the Taste (which vse of the Tongue is common to Man and beast) to distinguish betweene all the varieties of Savors; wherefore *Aristotle* in the 11. Chapter of his first Booke *de Historia Animalium* saith, there is in the mouth γλωττα κομὴ ἀισθητικόν, A Tongue which is the Sensor of tastes. The taste which the Tongue hath it receiveth especially from the Coate which inuesteth the mouth, and particularly from that part of it which couereth the tongue. For whilst wee chew our meate the Tongue rowleth it selfe on euery side of the mouth and applyeth it selfe to the Viands to take a say or Taste of them.

The primary vse. For tasting.

Moreover, because we can thrust or lill out our Tongues, wee are able to discern of the Savors of those things also which are without the mouth if the Tongue do but touch them, especially with the very tip, for there saith *Aristotle* the taste is most quicke, in the 27. Chapter of his second Booke *De partibus Animalium*, and therefore saith he, in Fishes onely the very tippe of the tongue is loose, the rest is fastned downe vnto the Soale of the mouth.

The Tip of the Tongue.

Concerning the vse of the Tongue in the voyce, *Hippocrates* hath made mention in his Booke *De Carnibus*. As also *Aristotle* in the eight Chapter of his second Booke *de Anima*, for it is the very organ of Articulation, so we saide before that those Birds which haue broad tongues may easiely be taught to prattle, as we see in Parrats. *Euripides* therefore calleth the Tongue ἀγγελος λόγων, The Messenger of the Speech. And therefore a mans Tongue which is best proportioned and most at libertie, attaineth to the greatest perfection in the deliuey and variety of the voyce. For although a Parrat, a Stare, and such like Birds can moderate their tongues to a kinde of faigned distinction of Sounds, yet in man the sound is more expresse and better articulated. Beside, saith *Hippocrates* in his Booke of the *Epilepsie*, the Tongue of a man is the messenger of the Braine, that is, as *Bauhine* well enterpreteth it, of the Understanding and the Will; but in other Creatures it deliuereth onely the affections of the Senatiue soule which *Galen* calles *Rationem delitescentem*, A silent shadow of reason, which he attributeth to all Creatures denoyde of reason. So we see euen in the tongue of a man, sometimes it expresseth onely those things that fall vnder the Sense, as when wee cry for paine, or for Foode and succour; sometimes those things that fall vnder our vnderstanding as in Discourse.

For speech.

A mans tongue the messenger of the braine.

The Secondary Vse of the Tongue is for mastication or chewing, or breaking of the meate, and for diglutition or Swallowing.

The secondary vse Chewing.

By this motion of the Tongue those Creatures that want Teeth doe swallow their meate whole, as Birdes; and those that haue teeth doe with their tongues mooue their Viandes vnto their teeth whereby they are mitigated and broken, and so receyue in the mouth a good preparation for the Stomacke, which otherwise would not nor could not so easilie concoct them, for shreadde meate is more easily boyled then a whole loynt.

Againe, the Tongue helpeth the Diglutition by turning the meate ouer it towards the Gullet. By the Tongue also wee can licke and whistle, or varry the sounde of any Fife or Pipe, or such like. All these good offices the Tongue dooth in a man, in other Creatures but one or at least not all. For in the perfection of Creatures (sayeth *Galen* in the Fiffe Chapter of his second Booke *De Semine*.) Nature proceedeth by degrees from a Plant. The first Degree, is of those Creatures which haue onely the Sense of Touching; more perfect are those that Taste, yet more that Smell, then those that Heare: and finally, she addeth the Sense of Seeing which is the ytmost perfection of the sensatiue Soule.

Swallowing.

So steered T. tongue F. d. 1

Degrees of perfection in Creatures.

The Muscles of the Tongue are assistant vnto it in the performance of all his Functions of Speaking, Tasting and Rowling of the Meate: and therefore there are three kinde of Muscles belonging vnto it which we may call *Locutorij*, *Gustatorij* and *Gibi reuolutores*, the Speaking, the Tasting and the Rowling Muscles.

The muscles of the tongue.

The

Table 14. Figure 1. and 2. sheweth the tongue cut from the bodie, and the Muscles thereof. In the first the right side of it, and in the second his Muscles some-what uncoverd. Figure 3. sheweth the body of the Tongue divided according to the length of it and his Ligament.

TABVLA XIII.

AAA, The tongue inu-
ested with a Coate com-
mon to the mouth.

BB, A portion of the coate
compassing the mouth cut
from the mouth according
to the sides of the lower
jaw.

C, A part of the same coate
cut from the inner part of
the Palate together with
the tongue.

D, The Muscles cald *Basi-
Glossi*, according to *Vesalius*
the first, but in our ac-
count the fourth, or the
sixth of the bone *Hyois* ac-
cording to *Falopius*.

E, The Muscles cald *Cerato-
glossi*, or the second Mus-
cle according to *Vesalius*
and in our account the fifth.

F, The Muscles called *Styloglossi* or the third Muscle. G, The Muscles called *Myloglossi*, or the fourth Muscle according to *Vesalius*. H, The flesh consisting of the Glandules, or the ninth Muscle of the tongue according to *Vesalius*. I, The Ligament of the tongue. K, L, L, The Muscous substance of the tongue, and the fibres thereof.

The chiefe vse of it in man is speech, the chiefe vse in Beasts is tasting, because they want hands to gather and apply their meate vnto their mouths as men haue: but both men and beasts when their meate is in their mouths doe rowle it with their tongue, or turne it ouer into their Gullets. The tongue must therefore bee moouable and haue Muscles, which Muscles are of two sorts, some Common, others Proper. These are accounted common Muscles which belong vnto the bone *Hyois*, and those proper which haue their originall from other where, and do determine into the substance of the tongue, and they are accounted five paire called *Styloglossi*, [tab. 14. fig. 1, 2. F] *Myloglossi*, [tab. 14. fig. 1, 2. G] *Genioglossi*, [tab. 14. fig. 1, 2. H] *Basiglossi* or *Tp siglossi*, [tab. 14. fig. 1, 2. D O] and *Ceratoglossi*. [tab. 14. fig. 1, 2. E] But of these we shall entreat particularly in the Booke of Muscles, heere it is enough to haue pointed them out.

Five paire.

The roote of
the Tongue.

These Muscles being remooued, at the roote of the tongue there appeareth a kinde of flesh made of many glandules and fat mixed together, which saith *Archangelus* doth not deserue the name of a Muscle, so saith also *Columbus*, yet hee reckons it for the 11. Muscle, because the Anatomists before him accounted it for a muscle. But a muscle is not made of glandules but of fleshy fibres.

The vse of the
kernels.

This heape of Glandules [Table 14. figure 1, 2. H] groweth to the roote of the Tongue that it might continually be moistned, for without moisture there can be no Gustation. So in the stomacke there can be no concoction without Elixation or boyling, wherefore Nature ioyned to the Stomacke the *Pancreas* or Sweete-bread a glandulous body, that from thence might continually steame moyst vapors, that so the concoction of the stomacke might be made by *Elixation* or boyling. Beside, the moysture which the Tongue receiueth from these glandules makes it more glib and easy to be moued; for if it be dryed it will not mooue

mooue so readily, as we may see in those that are very dry, and in hot burning Agues when the humour or moysture of the Tongue is exhausted. Beside the Glandules, the Almonds also of the throat (as we remembred before) do continually moysten the Tongue and help his motion. And thus much of the Tongue.

CHAP. XXXIII.

Of the Sense of Tasting

WEE said before that there were three things required in euery Sense; the Instrument, the *Medium* and the Obiect. Which three we will shew in this fourth sense of Tasting as far as we can gather out of Anatomy.

The Physitians (following *Galen* in his Booke *de Instrumento odoratus*, and the fifth Chapter of his 7. Booke *de Placitis*) doe determine that the instrument of the Taste is the Tongue, and that it is affected to Savors as the Eye is to colours. But as in the Eye there is one particle which is said to be the most principall instrument of Seeing, the other but assistant: so in the Tongue there is one similar part which is the principall instrument of Tasting, and that is the rare and laxe substance thereof, which is therefore rare and spongy, that it might be better steeped with the moysture wherein the Savors are conuayed. The other parts of the Tongue are but helpers and handmaids all contributing vnto the principall part. This substance, call it flesh, or pulpe, or what you will, because it was made to receiue all Savors was to be deuoyde of all Sapor, that is, *insipid* or hauing no Taste all as we vsually speake, and that it is so any man may perceiue if hee eate of the Tongue of any beast boyled fresh and without any sauce.

The instrument of tasting

The principall particle.

The matter wherein the formes of Savors do consist which we call *Natura subiecta*, is moyst: for without moysture (saith the Philosopher in the 20. Chap. of his second Booke *de Anima*) nothing can make an impression of a Sapor, and euery thing that maketh this kind of Sensation or moueth this Sense hath humidity in it, either *Actu* or *potentia*, that is, eyther Actually and Readly or in Possibility; and by how much a thing is the moyster, by so much is it the more sauoury, because all things when they are moyst doe make a better impression of their Sauour then when they are hard.

The matter in which tastes do consist.

Hence it is that those things that are hard as Pepper and such like; do not make shew of the gustile qualities vlesse their vpper and superficiall parts do giue as we say, or melt, or be moystned. The sweetnes of Sugar we Taste better when it is melted, and a corne of Salt will strike the sense much more after it is dissolued then before. An infusion of Rheubarbe is much bitterer then a peece of Rheubarbe held in a mans mouth. Seeing then that Savors are not perceiued but as they communicate their qualities to moyst substance; it followeth that the Instrument of this sense must neyther be actually moystned; yet of such a substance as cannot be moystned: but it must be Potentially Moyste and Actually moystned, yet so that when it is moystned the Nature of it must be preferued.

Hence it is that when the Tongue is eyther too dry or too moyst it doth not Taste well. For example, if a man Taste of any sharpe or vehement thing as Pepper, and then presently Taste of another thing, he is not able to iudge well of the latter; the reason is because the Tongue is already possessed and forestalled or taken vp with the former sharpe humour. So likewise we see that those that are sicke thinke all things bitter, the reason is because their Tongues are moystned with a bitter iuice.

Why sick folk thinke all things bitter.

The Tongue therefore was made of an earthy and dry substance; for albeit because of the softnesse it may seeme to be moyste, yet this moysture is not *Innate* but an acquired moysture distilling perpetually out of the braine which insinuateth it selfe into the Tongue as water doeth into a sponge. That this is so it is euident, for if the distillation out of the head be stayed, the Tongue is presently exiccared, yea so parched by hot vapours eleuated from the Liuer, the Stomacke and the Lungs, that it becommeth rough, yea in Agues it cleaueth or choppeth and the marks or scarres of those fissures remaine many yeares to be seene; which thing (saith *Bauhine*) I haue experience of in my selfe, for 17. yeares since I had an Ague, and my Tongue cleaued or chopped in the middest, and yet the marke of it is manifestly to be seene.

Bauhine of himselfe.

Galen therefore in his Booke *de Odoratus Organo*, and in the sixt Chapter of his seauenth Booke

Booke

Booke *de Placitis*, hath truly taught vs that the instrument of Tasting was made of a moyst substance, where he intendeth to diluier the qualities of the instruments which are most appropriate to the particular Senses. For if the Tongue bee too much exiccated, the *Perceiuaunce* or knowledge of Sapours must needs perish: and therefore Nature set the Almonds neare the Tongue least the ayre that is continually drawne and let out by Inspiration and Expiration should dry it too much. And so much of the Instrument.

The medium
of the taste.

The *Medium* of this Sense we take to be the coate of the Tongue, as the Cuticle or Scarf-skin is the *Medium* of the Touch. For (sayth the Philosopher in the 14. Text of the second Booke *de Anima*) all things that are apprehended by any Sensation we apprehend by a *Medium*, there being no Sensation made by immediate contraction of the Instrument and the Obiect; although afterward in the 10. Chapter of the same Booke (not so well aduised) he denyeth that either the Taste or the Touch haue any *Medium*, to which place we refer him that is desirous to know his reasons.

The obiect.

The Obiect of the Taste are all things that haue any Sapor or Gustable qualities in them. But the qualities of Gustable things are of two sortes, some properly belonging to the Sense of Tasting as Sapours (For as the obiect of the Sight is Colour, so the obiect of the Taste is Sapor; yet nothing that is without moysture exhibiteth any Sapor to the Sense) others are Common to all the Senses as the Magnitude of that which is Gustable, the Number, the Situation &c. Wherefore we say that the Tong doth Taste the Sapor of wine, not the wine; yet from this Sapor the Soule gathereth that it is wine which we Taste. For wine as it is wine, and sugar as it is sugar are not the Obiects of the Faculty of Gustation, but as they are indowed with Saptors or Gustable qualities. The Soule indeed by discourse of Reason distinguisheth betweene a sharp Taste and a bitter, but it is by the mediation of the Sense of Tasting; when the Sensible qualities of those sharp or bitter things do moue and affect the Faculties of Sensation. But that a Sapor may be exactly iudged of or apprehended, the body wherein that Sapor is, must be broken betweene the Palate and the Tong, and therefore the Palate and the Tongue are compassed about or inuested with one and the same coate.

Hence it is that euen the Palate helpeth the Taste, because also it receiue the like distribution of nerues of the same coniugation the tongue hath.

The kinds of
savors.

The kinds of Saptors as the Philosopher saith, are accounted after the same manner with the kinds of Colours. For as white and blacke are contraries, and the other Colours leane to this or that Contrary; so *Sweete* and *Bitter* are the two simple contraries; to sweete adheareth that we call *Fatty*: to *Bitter* that which is *Salt*: and betwixt these are Byting, as Pepper, Harsh as vnripe Sloes, Sowre and sharpe as Vineger. For these are the differences of Saptors according to the Philosopher; concerning which he that will know more let him resort to *Galen* his first Booke *de simplicis. Facultat.* where also he shall finde what was *Platoes* Philosophy concerning the difference of Saptors. I must not insist vpon all.

The conclu-
sion.

We conclude that the Tongue as the Instrument of the Taste being neyther drye nor too moyst, nor steeped or dewed with any ill iuyce, doeth through his coate as through the true *Medium* Receiue and Perceiue the Saptors that consist in a moyst body, and that by a Faculty or Power yssuing from the braine by the nerues of the third and fourth coniugation, and penetrating into the Instrument of Tasting, that is, the Flesh or Pulpe of the Tongue.

For the Faculty (sayeth *Plato* in *Theateto*, and *Galen* in the sixth Chapter of his 7. Booke *de Placitis*) which yssueth from the first Sensator, that is, the Braine, and through the Nerues penetrateth into the particular Organs of the Senses, and there *Perceiue*th and iudgeth of all their alterations; is a common Faculty: and therefore wee call the braine the Common Sensator, and apprehension thereof the Common Sense. And thus much of the foure Senses (The first hauing beene discoursed of in the second Booke.) Now we come vnto the Voyce.

CHAP.

CHAP. XXXIV.

Of the Larynx or Throtle, which is the Organe
of the voyce.

The Rough Artery is diuided into the pipe which consisteth of Semicircular gristles with a membrane, and the head of it which we call the Larynx. It is called in Greek *ἀρὺξ* of *ἀρὺγιζω*, which signifieth to cry with open throat: or of the particle *λα* which of it selfe signifieth nothing but in composition adsignifieth a kinde of greatnesse, and the word *ἀρὺξ* to draw, because in the forming of the voyce we draw our breath deepe. Some call it *ἀρὺξ* but that is properly vsed for the Fauces or Chops; for the Pharynx is before the Larynx: others deriue it of *λα* and *ἀρὺξ* which signifieth to be lifted vp, because when we swallow or raise our voyce very high or vtter it very base, the Larynx is eleuated as any man may see with his eyes. Some call it the knot of the Throate.

The names & reasons thereof.

The Larynx therefore is the head or vpper end of the Rough Arterie ioyned in continuitie with the Fauces, compounded of great gristles (vnlike those that bee in the rest of the weazon both in the figure and magnitude) Muscles, Membranes, and common Organs: to be the first and most principall Organ of the tuning of the voyce; for in it the voyce is first formed.

What it is.

It is situated in the Necke, because it is the way of the Ayre, and in the very top of the Rough Artery that vnto it the breath which is the matter of the voyce might easily run vp from the lungs. Neere the Chops also, the mouth and the tongue that the voyce might instantly be changed into speech. Moreouer, because it was necessary that it should be perpetually dilated and constringed together with the Organs of Respiration therefore it was placed on the outside afore the Gullet, that it might not be pressed with the weight of any thing lying vpon it: yea and this position is a great furtherance to swallowing also. For when we swallow our meate the Gullet is drawne downward, but the Larynx resulterth vpward and helpeth the swallow, as wel by giuing way therto and leauing scope and roome, as also by depressing the meate when it starteth vp as that is falling. It is placed in the very middest of the necke because there is but one Throtle, as also other single Organes are placed in the middest, that the body might be equally ballanced. Now there was but one, that the voyce might bee but one. For if we should haue vttered two voyces at one time, wee could not but haue confounded two acts or affects of the minde.

The situation

And reasons thereof.

The figure is round and circular but imperfect, bunching out before, that it might bee more secure from outward iniuries, behind depressed, that it might giue way to the Gullet and leaue space to swallow. Again it was round, that it might bee concavous or hollow, that so the voyce might be more perfect by a plentiful affluence of the breath thervnto out of the lungs. The lower orifice also of the throtle is larger then the vpper (saith Galen in the second Chapter of his seauenth Book *de usu partium*) that in expiration the ayre might ascend more plentifully thereunto to make a base voyce. Finally, it is most like a Quail call of any thing in the world which indeed is made in imitation of this worke of Nature.

The figure.

The magnitude thereof is diuers according to the diuersity of the age, which variety the voyce also followeth. For in children when the Larynx is narrow the voyce is sharper, smal, or treble because a little ayre is swiftly moued through a narrow passage; on the contrary in old or elder age the Larynx is wider, and receiueth from the Lungs a greater quantity of ayre, whence it is that the motion is not so swift and so the voyce becommeth base, moreouer the length or shortnesse of the Larynx beare a great sway in the basenes or shrilnes of the voyce.

The magnitude

It is tyed to the rough Artery by the helpe of muscles, of Membranes, as also to the Gullet, the Chest, and the bone *Hyois*, moreouer to the principall parts by the mediation of common Organs.

The connexion.

The parts whereof the Larynx is compounded are Gristles, Muscles, Membranes, Veines, Arteries and Nerues, together with the Glandules which grew thereto. And it was necessary it should be compounded of such a substance. Gristly, that it might be hard, dense and thicke, able to resist outward iniuries. Again, because it is the way of the breath it was

The parts. Why Gristly.

fit

fit that the cavity should be made of a hard body that might alwayes stand open for egresse and ingresse of the Ayre. For (saith *Galen*) if it had beene made of flesh or a membrane, the hole of it would haue false and the passage should not haue bene so free for the breath and so the body haue beene depriued, not of voyce onely, but of life also, because the respiration would haue bene intercepted.

Why not bony

If it had bene bony the hardnesse thereof would haue pressed vpon the gullet and so haue hindred digestion or swallowing, beside the watery weight would haue drawne downe the tongue and the bone *Hyois*, and hindered their actions; it would haue needed great muscles to haue moued so heavy a body which must haue taken vp a greater place then in so narrow a roome could be allotted to them. And if the bones had beene so fine and thin that all these inconueniences had beene preuented, then it would haue easily bene broken being placed outward, for bones will not yeeld as gristles doe.

Columbus opinion that it is bony.

I know well that *Columbus* is of opinion that it is bony in growne men, which hee auoucheth vpon his owne dissection of innumerable bodies (those are his words) although hee confesseth that in young children it is gristly as not hauing attained his hardnesse and solidity. One argument also he addeth, which is, that the substance is medullous or marrowy as he hath often found, in which one thing bones differ from gristles. Hee also reprehendeth *Galen* for cutting vp Apes and not obseruing that their throtles were bony, and *Vesalius* for shewing the Throtles of beasts in his publike dissections. But *Fallopins* whom wee esteeme the more oculate Anatomist saith, that sometimes he hath found the first and second gristles bony in very old men, yea sometimes before extreme old age; but the third and the fourth gristles saith he, I neuer saw bony, neither can I approue of their opinion that thinke the Larynx is bony and not gristly, vnlesse it be imperfect, because Nature intended it to be bony. For (saith *Fallopins*) if this were so, then we must confesse that no man hath the instrument of his voyce perfect till he come to be old or stricken in yeares, which must not be granted. Of the same mind also is *Laurentius*.

Disproued by Fallopins.

Other reasons why it must be gristly.

Bauhine proceedeth further to prooue it gristly on this manner. It is the instrument of the voyce, and therefore there must be a proportion betweene the ayre that is beaten, and the body which beateth it, that so it may resound for the forming of the voice; for the voice is nothing else but a percussion of the Ayre. And although sounds doe arise from hard bodies not from soft, as a sponge, a Locke of wooll, or such like; for that the Ayre is not broken vnlesse it light against a solid, hard and smooth body; yet it must not be perfectly hard, for such an one doth not readily cut the ayre, but ouerturnes it. Nor too soft, for then it yeeldeth and maketh no resistance, and therefore cannot make any sound. Such a body therefore which yeeldeth moderately, and beateth the ayre gently, is the cause of the voyce, now such a body is a gristle. Finally, it was made gristly (saith *Galen* in the fourth Chap. of his Booke of the dissection of the instrument of the voyce) that it might be a fit foundation for the other parts whereof the Larynx is compounded: and that the Muscles might better arise therefrom and be implanted thereinto.

Not of one gristle.

But it was not fit it should be made of one entire gristle without any articulation, and so immouable, for then it could not haue bene either shut or opened, dilated or contracted. It was therefore made of many annexed one to another and hauing motion, not Naturall, such as is in the Arteries, but voluntary depending vpon the will. For the chiefe vse of it being in inspirations and expirations, it was meete we should be able to moderate it at our pleasures. Add hereto, that being the instrument of the voyce to admit or expell our breath it was more then necessary we should haue a voluntary command ouer it. To this purpose Nature also furnished it with muscles, and them with nerues for motion, veines for nourishment, arteries for life, and membranes for their strength. She added also glandules to keep them all moyst.

The number of the gristles.

It is made of 3. gristles (saith *Galen*) we say 4. so doth *Fallopins* and diuers others. The motions of the Larynx are double, (that is) whereby it is dilated and constricted, shut and opened; and therefore there was neede but of two articulations, each of which serue each motion. So that the dilatation and constriction is made by that articulation which is betwixt the first gristle and the second. The opening and shutting by that which is between the second and the third.

The muscles.

The Muscles of the Larynx are eyther common or proper, the common Muscles are fixe, that is, three paire. The first paire are called *Bronchij* [table 15. fig. 7. X X] because they cleaue to the rough Artery. The second paire are called *Hyoidei*, or rather *Hyothyroidei*, [tab.

Table 15, Figure 3. sheweth some Muscles of the Larynx with a part of the Nerue. Fig. 4. sheweth all the proper Muscles, the Cleft, the Epiglottis or After-Tongue and the Gristles. Figure 5. sheweth the backe part of the Larynx with the Muscles separated, the Gristles and the Epiglottis. Figure 6. The foreside of the Larynx with some muscles. Fig. 7. the transuerse muscle of the Gullet, also 2. common muscles, together with the Recurrent Nerues.

TABVLA XV.

b, 4, 5, 6, 7, Epiglottis or the After tongue.
 * 4, The beginning thereof.
 †, 5, The roote and foundation thereof.
 cc, 5, The Gristle called *Arytenoides* or the *Ewre-gristle*.

d, 4, The *glottis* cleft or whistle.
 e, 4, The internall muscles belonging to the *shield-gristle* or the 4. paire of proper muscles
 f, The backward *Ring-Ewre* muscles, or the second paire of proper muscles.

g, 4, 5, The *Ewre-muscles* or the fift paire of the proper muscles.

h, 3, The muscles called *Hya-thyroides* or the 2. paire of common muscles belonging to the bone *Hyois* and the *shield-gristle* of the Larynx.

i, 3, 7, The Gullet.

k, 3, 6, The forepart of the rough artery.

l, 3, 7, The muscles of the Gullet called *æso-phagici* or the 3. paire of common muscles.

m, 3, A portion of the nerue descending into the second paire of common muscles.

nn, 3, 4, 5, The *Shilde-gristle*, parted in the 4. figure that the *Glottis* and the muscles might better be seene. In the 5. figure is shewed the Hollow side of the *Shield-gristle*, in the sixt the outward and the foreside.

o, 4, The cavity or ventricle.

r, 4, The laterall *Ring-Ewre* muscles or the 3. paire of proper muscles.

s, 4, 6, The forward *Ring-shield* muscles or the first paire of proper muscles. In the 6. figure one of them is separated, the other remaineth in his owne place.

t, 5, The spine or ridge of the *Ring-gristle*.

u, 6, A cavity in the midst of the *shield-gristle* made for the *Epiglottis* or After-tongue.

xx, 7, The muscles of the weazon or the first paire of common muscles. yy, 7, The recurrent Nerues.

FIG. VII.

FIG. V.

FIG. IV.

FIG. VI.

[tab. 15. fig. 3. b.] The third paire are called *æso-phagici* [tab. 15. fig. 7. l.] The proper muscles are ten or five paire, of which fixe doe dilate and foure do constrict. Some of these are placed forward, some backward, some without, some within.

The 1. paire we call the forward *Crycothyroides* [tab. 15. fig. 4. s, but in the 6. Figure the one is separated, the other remaineth in his proper seate.] The second paire we call the backward *Crycoarthenoides*. [tab. 15. fig. 5. l.] The 3. paire are called the laterall *Crycoarthenoides*. [tab. 15. fig. 4. r.] The 4. paire are called the Internall *Thyroides* or *Thyroarthenoides*. [tab. 15. fig. 4. c.] The 5. paire are called *Arytenoides*. [tab. 15. fig. 4. and 5. g.] The larger description and vse of these muscles looke for in the Book of muscles. We will come to the gristles of the Larynx which wee will handle particularly in this place because they make this notable Instrument of the voyce, and touch them but by the way in the discourse of gristles.

The Larynx therefore consisteth of 3. gristles say the Ancients, of 4. say many of the latter Anatomists, and we may so esteeme them: one called *Thyroides*, the other called *Crycoides* and the 3. *Arytenoides* which is double. These gristles when the muscles are removed from their outside are somewhat rough or rugged, to yeeld to the muscles more commodious originall and implantation. But on the inside they are smooth as being inuested with a Membrane, and beside smeared over with a slimy moysture. Of these gristles 3. are moued in the modulation or tuning of the voyce, that called *Crycoides* is immouable. The 1. and the 2. when men grow old become so hard that some good Anatomists haue thought them bony. But we haue proued before that they must needs be gristly not bony.

Iij

The

The names
of the gristles:

The 1. gristle.

The first is called in Greeke *σπουδιδας* the *Shield-gristle*, or *ἀσπίδιδας*, for *ἀσπίς* signifyeth a Buckler or Shield. It hath his name from the forme, [tab. 16, fig. 2, and 3, whole] for it is like the Target that the Ancients were wont to vse that was not round but long, the forme is yet kept by Heraldes and in triumphs where painted Shields are vsed of this fashion, the belly a little hollow and the back gibbous. This gristle lying vnder the bone *Hyois* couereth the forepart so as we can touch it, especially in men in whom it buncheth out more then in women, which bunch or knob they call *Pomum Adami*, *Adams Apple*, as if it sticke still in the throate of al his posterity, whereas the woman swallowed it well enough. But the true reason why it appears in men and seldome in women, is because the glandules which are placed at the Larynx doe make their necks equall and euen.

Pomum Adami

Why womens
throates do not
peare as mens

It hath foure sides because of the foure processes it hath behinde, for on the back it is not ioyned by the sides. In an Oxe (saith *Placentinus*) there are two manifest perforations aboue, through which the proper muscles of the Larynx receiue propagations of the Recurrent sinewes.

But one gristle

It is but one gristle, although oftentimes there runne a line through the middest. [tab. 16, fig. 2, and 3, betweene G, and H] *Vesalius* esteemeth it two, in men particularly, *Laurentius* especially in women; howsoeuer, it is the largest and broadest of all the rest, as taking vp the one halfe of the whole Larynx: it is therefore threefold as bigge as any of the other compassing the Larynx and the whistle or pipe thereof which wee call *Glottis*. Moreover in a man it is larger aboue then below.

Connexion.

It is tyed to the bone *Hyois* by his vpper processes, and by the lower to the 2. gristle.

Substance.

The substance of it is Gristly, thinne yet hard, the better to defend the *Glottis* or whistle, and to helpe the breaking of the ayre in the forming of the voyce. In old men this gristle is sometimes so hard that being exceedingly drier it becommeth Bony, yea sometimes a very bone. It beginneth to grow hard at the sides, the middle line remaining Gristly for the most part, yet euen that also now and then groweth to be a bone. The exterior superficies of this gristle is conuex or gibbous, and toward the ends of the sides it is rough, into which place the first paire of the common muscles of the larynx are inserted, as also those take their original which we account for the third paire of common muscles of the gullet. On the inside it is hollow to forme the long cavity of the Larynx, by which meanes the voyce becommeth full & elegant, for we see that hollow things do sound better then plaine, as it is in bells.

4. Processes.

It hath 4. processes, [tab. 16, fig. 2, and 3, IKLM] two aboue and two below, on each hand of the sides one. With the two vppermost [tab. 16, fig. 1, IK] it is tyed by a ligament somewhat long to the lower sides of the bone *Hyois*; [tab. 16, fig. 1, BB] which by certaine distances is strengthened with little, long, round and gristly bodies, [tab. 16, fig. 1, aboue K, I] especially it hath vse of them when the Tongue is put out or drawne in again.

The two lower processes in men are shorter then the vpper (but in Sheepe quite contrary) [tab. 16, fig. 2, and 3, LM] and are articulated by *Arthrodia* [tab. 16, fig. 1, from L, to I] with a flat head to a shallow cavity in the second gristle, that the *Shield-gristle* might be moued vpperward and downward.

The cavities.

On either side nere the processes it hath certaine recurued or bowed cavities. The vpper of which being in the middest [tab. 16, fig. 2, and 3, G] is the lesser, made for the *Epiglottis* to raise it vp easily and suddenly. The lower are on each side one [on both sides at H] whereinto the anterior muscles are implanted. [tab. 15, fig. 6, f] Finally this *Shield-gristle* is mouable, partly by articulation, partly by flexion. The Articulation may be called *Arthrodia*, by which it is drawne length-ways vpperward and downeward, and these ioyns are at the lower processes which are ioyned to the second gristle, the draught is made by the first and second paire of the common muscles. It is also drawne in length without a muscle being compressed by the three paire and loosened by the flexible substance of the gristle. It is also mouable by flexion, for because it is thin it is also flexible, whence it stretcheth in breadth, it yeeldeth downeward and againe returneth vpperward, and so the cavity of the Larynx is lifted vp and depressed, straightened and relaxed.

The vses of the
Shield-gristle.

The vse of this gristle is foure-fould, the first to make the cavity of the Larynx, the second to establishe the *Glottis* or whistle, the third to affoord an implantation or seate of rest for the muscles. And finally, to fashion out the articulations necessarily required in the motion of the Throtle.

The 2. gristle.

The second and lower gristle is called *κεκλιδιδας*, the *Ring-gristle*, [tab. 16, fig. 4, 5, and 6,] for so *Galen* and *Oribasius* his *Epitomizer* call it because it is like a Ring: and indeed it is very like

like that bony ring which the Turkes weare vpon their right thumbes when they shoot, that they may draw the bow string with greater strength. It is commonly called *Innominata*, the Gristle without a name, because the Ancients before *Galen* gave it no name, the reason hee giues *de dissectione musculorum*, because they could liken it to nothing in the whole world; haply saith *Banhuine* because the actions of the *Larynx* are performed by motion, now the other three do moue, but this being as it were the Basis and foundation of the rest is altogether immouable.

Why called *Innominata*.

It lyeth vnder the *Shield-gristle* and is the Basis of the other gristles which it sustaineth. It lyeth vpon the first gristle of the rough artery to which it is ioyned by a ligament, & the greatest part of it is in the backpart of the *Larynx*, yet it compasseth it round about like a ring, establishing it by his hardnes. And it was very necessary it should be like a ring or perfect circle, partly that the pipe might be alwayes open, and so way made for the ingresse and egress of the Ayre, otherwise in the motion of the *Larynx* the semicircular gristles of the weazon would haue beene compressed: partly lest when the gullet is dilated or stretched by the swallowing of any hard and thicke substance, the pipe or weazon which is the way of the breath should be compressed, whence suffocation or strangling must needs follow. On the outside & fore side it is gibbous, narrow, slender and round like the other gristles of the weazon. [tab. 16, fig. 4, and 5, R] Gibbous the better to defend it selfe, to helpe the shield-gristle to make the cavity, to helpe the sound and to dulcifie it. Thinner that it might not hinder the ayre that was to be driuen vnto the shield-gristle; for if it had in this place beene broader, then had the shield-gristle wanted place to moue it selfe in. But behinde where it doth not compass the shield-gristle it was fitte it should be broader, and so well might be; [tab. 16, fig. 4, 5, and 6, S] broad I say like the head of a ring whereon the scale is grauen, and flat: otherwise the roundesse of it together with the hardnesse would haue hindred the swallow.

The situation

And reason thereof.

The figure.

The substance.

Moreover it is also thicker, especially towards the vpper part, and that because of the articulation; and that the slit and the whistle might be on euery side defended and established: adde hereto another reason why it was thicke, to wit, that from thence some muscles might take their originall. For in the very middest which is the broadest part there standeth vp a rough line [tab. 16, fig. 6, T] which *Galen* in the 7. chapter of his Booke *de dissectione vocal. Instrum.* calleth the *Spine or the ridge of the gristle without a name*. By this line is made a shallow cavity on each side [tab. 16, fig. 6, V X] wherein the second paire of proper muscles are commodiously situated. But in the vpper and backward part it hath on each side a long knob [tab. 16, fig. 6, Y Z] or if you had rather call them bunching processes (*Galen* calleth them *Shoulders*) with which the *Ewre-gristle* [tab. 16, fig. 9, "] is articulated; in which place it is alwayes harder & thicker; so that that which seemed in childhood gristly in the middle or growne age becommeth (or at least seemeth) to be bony. In the middest it also swelleth a little on both hands & becommeth thicker [tab. 16, fig. 6, N O] and excauated, in which cavity the lower processes of the *Shield-gristle* whose heads are flatted, are strongly ioyned to this ring gristle by a plaine articulation. Finally, in the lower part [tab. 16, fig. 4, 5, 6, S] there runneth downward a kind of proceffe, from whence the third paire of proper muscles do arise.

The quantity.

This ring gristle by how much it is lesser then the *Shield-gristle*, by so much it is greater then the *Ewre-gristle*: it is also somewhat narrower then the lower Basis of the weazon, wherefore the lower part of the *Larynx* is larger then the vpper orifice which is in the chops. It is the hardest and the thickest of all the rest (although it be not all of an equall thicknes) because the others rest vpon this as vpon a Basis; wherefore also it is immouable that vpon this the other gristles might be both moued and articulated, and the muscles which belong vnto the others herein also firmed and established.

The connexion.

It is tyed to the *Shield-gristle* by the helpe of membranes or ryes produced from the 1. to the 2. these ryes are double, as also are those which couple the 2. with the 3. as *Galen* teacheth in his Booke *de voce & anhelitu*, and these membranes do inuest not onely the middle part of this Ring-gristle but also the whole Basis of this *Shield-gristle*.

The 3. gristle. It is indeed double.

The third Gristle of the *Larynx* is in the sides [tab. 16, fig. 7, 8, 9,] and is called *apud Graecos*, that is, the *Ewre*, because it is like an *Ewre* out of which water is poured if you marke the two vpper processes couered yet with their membrane, or because it is like the spout of a wine por. This is commonly esteemed and receiued for one gristle, because they are not wholly separated, & performe their action together not asunder. Whilst it is yet couered with his coate it is like an imperfect Triangle: but if you take off the membranes wherewith it is couered, you shall perceiue that it is made of two gristles [tab. 16, fig. 7, 8, 9, 10] which aboue and below, are

loosely ioyned by the mediation of ligaments and of the membrane that compasseth the *Larynx*, but in the middest they cleave asunder or stand separated. In the middest where it is thicker it hath a ioynt whereby it is ioined to the top of the ring gristle where it regardeth the gullet: and because the gristle is double the articulation also is double, which do on each side receiue into their cavities [tab. 16. fig. 8, 9, 11] the swellings of the ring gristle [tab. 16. fig. 6, 7, 8] that so it might the fitter be straightned and dilated.

The substance.

The substance of this third gristle differs, from the other two, as being softer, that it might not need the greater muscles to moue it; it is also slenderer, fatter and moyster that it might not be dried vp by the ayre, much lesse also then the rest, that the passage should not be angustated or straightned.

The processes vpper.

It hath processes aboue and below. The vpper [tab. 16. fig. 7, 8, 9, 11] which being ioyned do cary the fashion of an *Emre* or spout pot, are recurued outward, that they shold not incline inward and so fill vp the cavity, whereby the free passage of the breath would haue beene interrupted. They are lax, soft, fat and flexible, that they might follow the motion of the whole glottis or whistle. These vpper processes are not altogether separated asunder, least one shold

Table 16. Figure 1. Sheweth the whole Larynx composed of his gristles with the bone *Hyois*, and a part of the *weazon* or pipe. Figure 2. and 3. Sheweth the *Shield-gristle*. But 4, 5, and 6. Figures shew the *Ring-gristle* or that which is without name. Figure 7, 8, and 9, sheweth the *Emre-gristle*. The 10. the *Epiglottis*. The 16, sheweth the gristles of the *weazon*.

TABVLA XVI.

A, 1, The bone *Hyois*.

BB, 1, His processes.

C, 1, Gristly swellings and membranous ligaments set by course to which the *Shield-gristle* is ioined by processes.

D, 1, The laterall *Shield-gristle*.

F, 2, and 3, Sheweth either face of this gristle.

From G, to H 2, 3, A line in the midst of the first gristle.

I, K, 1, 2, 3, 4, The vpper processes of the *shield-gristle* articulated to the bone *Hyois*.

L, M, 2, and 3, The inferior processes of the same *shield-gristle*, which in the 1. figure are articulated to the *Crycoides* or *Ring-gristle*.

N, O, 6, The seat of the *crycoides*, or *ring-gristle* where these processes grow into one.

P, 1, 5, The backe part of the *Ring-gristle*.

Q, 4, 5, The inside of the *Ring-gristle*.

R, 4, 5, The lower circular region of the *Ring-gristle*.

S, 4, 5, 6, The hinder part of this circle.

T, 5, 6, A hinder line of this gristle.

V, X, 6, A bosome on both sides this gristle called also *ventriculus*.

Y, Z, 4, 5, 6, Two swellings of the *Ring-gristle* which goe into the bosome of the *Emre-gristle*.

a, 1, The *Arytenoides* or *Emre-gristle*.

b, 7, 8, 9, Two parts of the *Emre-gristle*.

c, 8, 9, The empty space of this gristle which is couered with membranes.

d, 8, 9, The sides of this gristle by which it is ioyned to the ring gristle.

e, 8, 9, A proesse of this gristle making a little tongue.

f, 9, the vpper part of the 3. gristle like a spoutpot or an *emre*

g, 10, The basis of the *Epiglottis* regarding the Larynx continued with the *shield-gristle*.

h, 10, The tip of the After-tongue regarding the palate.

i, 10, The basis & top of the *Epiglottis* regarding the palate

k, Both sides of the gristles which make the pipe of the Rough-Artery much like the Latine C.

l, 1 The Rough-Artery.

m, 1, The membrane which on the backside, tyeth together the gristles of the *weazon*.

haue beene drawn from the other, and therefore in a man they are aboue ioyned with a membrane; but in Hogs it seemeth to be indeed but one proceffe. This part is so soft and flexible that when a man vomits it is reclined forward into the Larynx, and so shutteth the artery exquisitely, that no thing might happen to fall down into the lungs in our vomiting.

The lower proceffes made the *glottis*, or slit, or whistle by which the voyce is tuned. In that part they are wholly diuided [tab. 16, fig. 7, and 9, 2] because it was fitt that the slit or *glottis* should be mouable and free. For vlesse the egress of the breath be narrow the voyce cannot be formed. These proceffes also in the middle of the cavity of the Larynx are couered ouer with a fat membrane, whereby the slit is made the more firme. This *ewre-gristle* is made mouable, because without motion the Larynx cannot be streightned, and againe dilated; & therefore on either side in the lower end there is a muscle inserted.

The motion proceeding of the Articulation of the *ewre-gristle* with the *Ring-gristle* is fourfold. Flexion, Extension, and Motion to both sides; and so it is moued vward, downeward to the right hand and to the left. By flexion the *ewre-gristle* is driuen into the cavity by the 4. paire of proper muscles to shut the slit. By extension it is reuelled outward by the 2. paire of proper muscles to open the slit. Again, by the motion to the sides they are conioyned by the 5. paire of muscles to constringe it, as by the 3. paire they are separated to dilate it.

Now betwixt the flexion and extension of the *ewre-gristle* and of the rest, there is this difference, that in the others one motion is made for the behoofe of an other, but in the *ewre-gristle* both motions are of themselves profitable: the flexion, to constringe the slit that so the breath might be kept and the voyce formed at our pleasure; the extension to dilate it againe that the ayre might be plentifull received in.

The membranes which tye the gristles together do make certaine bosomes or cavities betwixt the *ewre* and the *shield-gristles*, into which, if in eating or drinking any thing fall, bee it but a little beare, which often hapeneth when the *Epiglottis* or *ouer-tongue* by laughter or speech when wee are eating is opened, whatsoever it is, I say, that passeth against our breath causeth a coughing. Of these bosomes or *sinus*, *Galen* seemes to make mention in the 11. chap. of his 7. Booke de *usu partium*, but since *Galen* (saith *Scuerinus Pinelus*) neuer any man made mention of them, but *Gasper Bauhine*, but where *Laurentius* had them I know not. *Placentinus* hauing got the hint of them, as should seeme from *Bauhine*, hath examined them very diligently in brute beasts and findes them seldome saue in Swine, Horses and Dogs. *Aquapendens* professeth that he findes them in all creatures vfed to the earth, but in some lesser, in some bigger; yea, so bigge as a man may put his finger downe them. Swine and Horses haue the largest, those of men are not so deepe.

The vse of these *sinus* is to alter the attracted ayre that it fall not with violence vpon the Larynx, such as is the vse of the deafe eares of the heart. They helpe (saith *Aquapendens*) to retaine the breath when the whole *glottis* is shut vp. In Dogs these *sinus* are like ventricles.

CHAP. XXXV.

Of the Glottis and Cleft of the Larynx.

That which is called in Greek *γλῶττις* is that body which maketh the Cleft or Fissure in the Larynx, which is the chiefe Instrument whereby the voyce is formed and uttered. [tab. 15, fig. 4, d] It hath the name from the likenesse that is betweene it and the tongue of a flute or other pipe. The Latins also call it the *Little Tongue*. For as the sound is made by the tongue of a pipe, so the voyce is made by the Linget of the Larynx, and as a man speaketh by his tongue, so the pipe is said to speake as it were by this *Glottis*; therefore we call it the *Whistle*.

It is situated within for the better generation of the voyce, and because the instrument might be freer from outward iniuries.

The figure of it is Ouall, sharpned at either side, yet more toward the *shield-gristle*, then toward the *ewre-gristle*. It is as long as the Larynx, as well that the gristles thereof might establish it, as also that a man might vary with his voyce high, low, or in a middle key, or as we say Treble, Base or Tenor: adde hereto that being so long it is able to admit a sufficient quantity of ayre. Morcouer as there is but one Larynx so there is but one *Whistle*, or cleft which beginneth

neath from the *ewre-gristle* & endeth into the *shield-gristle* that so it might be moued with voluntary motion, for we said before that only these 2. gristles were mouable, the middle which is the *Ring-gristle* is immouable.

How it is di-
uided.

Notwithstanding it maybee diuided into that which in the vpper part is made especially of the parts of the *ewre-gristle*, and that which in the lower part is formed of the membrane duplicated. This *glottis* and cleft runneth in the middle of the *Larynx* directly from the fore side backward, that the ayre yssuing out of the cleft and formed into a voyce might instantly touch vpon the top of the palate and the tip of the Tongue by them to bee articulated. And as the slit or cleft of a pipe is sometimes broad and long, sometimes narrow and long or short, so is it in this. For if it be long and broad, the voyce is base, if it be narrow it is treble or shrill: yet the magnitude is proportionable to the body; large bodies haue large slits, and litle bodies narrow, from whence comes the differences of voyces.

The composi-
tion of it.

The composition of it is very artificiall that the ayre which is the matter of the voyce might easily ascend and descend, and might beside receiue a fit repercussion. For it is made of both the processes of the *ewre-gristle* [tab. 16, fig. 7, 33,] or of the double *ewre-gristle*, and a portion of that muscle of the *shield-gristle* inserted into the processe of the *ewre-gristle*, which two are inuested with a membrane (making the Inner cleft, of which we shall speake by and by) which is not only thight to defend it but also moyst, which moysture is not only slimy but also fatty: and yet this *glottis* is moystened with a proper moysture of it own, lest our voyce should soone faile in discourse or other vse of it, if the *glottis* and the parts belonging to the *Larynx* should be exiccated. For being of a membranous substance, the frequent motion thereof in our speech or vociferation, the perpetuall ingresse of ayre & egress of the breath which is hot, might haue dried it if Nature had not prepared a proper moysture to keepe it in Temper: for as wee see whistles and pipes do need euer and anon to be moystened or else they will not sound so well, so if this *Whistle* of the *Larynx* had not had a naturall moysture, the voyce must needs haue fayled as we see it doeth in those that are sick of burning Agues, or trauell in hot weather, who cannot speake before they haue moystened their throates, or if they speake their voyce is stridulous or whining, which kind *Hippocrates* calleth *voces clangosas* in *Prorrh.*

Vox clangosa.

This moysture maketh the surface of the *glottis* or whistle to be slippery, yet is it beside smooth and glib, least the ayre lighting vpon vnequall parts and so yssuing vnequally should make the voyce harsh and vnplesant. Notwithstanding it was fit this moysture should be moderate, because those bodies that are too wet do sound worse then those that are dry. Whence it is that in rheumes and murrhes the voyce is hoarse, because the *Larynx* is dewed with too much moysture, but when the moysture thereof is Naturall it mayntayneth the voyce a long time without helpe, the rather because as we said, the moysture is not thinne that it should soone be spent, but viscid and fatty. And haply this made *Galen* say that the *glottis* was not onely membranous, but also fatty and glandulous. The *glottis* also by this meanes being soft and supple is more easily dilated and contracted, for it was necessary it should open and shutte as might serue best for the different expiration of the breath.

How the
voice becom-
meth hoarse.

Galen.

The rest of
the Glottis.
The motion
thereof.

For the *glottis* is either at rest or is moued, when it is at rest it serueth for the inspiration of ayre; when it is moued it is the instrument of the voyce, for the forming whereof it hath a double motion, one of dilatation another of constriction. The dilatation is the cause of deepe and baser voyces; the constriction is double, eyther to make the slit narrow and then the voyce is treble and soft; or altogether to shut it vp, whereby the breath is violently retained within, as when we strue to lift great weights, when women are in the pinch of trauel, & in such like violent actions. Wherfore as it is musculous it maketh the motions of dilatation and compression; as it is gristly it affordeth the ioints whereon the motion is made, and strength to support the motion that it should not be ouerturned by the breath; as it is membranous it is more fit to be dilated and constricted, the slit is formed the better and the muscle is defended.

The inner slit.

But beside the slit made by the *ewre-gristle*, in the inner cavity (and that in men only) there is formed another slit of the concourse of two membranes. For from the fore and middle part of the *Shield-gristle*, the membrane where with it is inuested on the inside in the middle iust against the *glottis* becommeth double and more solid, and attaining ouer to the backside of the *Larynx* is tyed to the inside of the *Ring-gristle* not farre from the *ewre-gristle* that so it might be kept stretched. Betweene these duplicated membranes there remaineth a long cleft running from the backside forward [tab. 16, fig. 7, 8, 9,] which is made broader when the *Shield-gristle* is dilated by the muscles, and so the voyce becometh base: as on the other side it is treble if it be angustated or streightned. And this is holpen by the diuision of the *glottis*, for both slits are

are

same time dilated, & at the same time constringed. *Arantius* maketh mention of this internall slit, and is of opinion that it is the chiefe place wherein the voyce is tuned, and that the division of the *glottis* is but assistant thereunto.

The use of the *Glottis* is, to be the chiefe Instrument of the voyce, or principall part in the *Larynx* which performeth the action, that is, the voyce; for that is the proper action of this Instrument. For the ayre passing is retayned and broken, and so produceth the voyce neyther can any voyce be made vnlesse the passage be straightned (and therefore *Galen* said well, that the *Larynx* without the *glottis* cannot frame or forme a voyce, no more then the eye can see without a cristalline) now it is straightned when it is moued, that is, when it is dilated or contracted, for it is in our power, saith *Galen* in the 9. chap. of his 8. Book *de placitis*, to shut or open the mouth of the *Larynx* when wee will, and as we list to close or loosen it, so wee make our voyce base or treble; for if we let our breath passe out lightly and gently, no sound accompanieth our expiration, but if the breath be powred forth suddenly & vehemently, then with the expiration there issueth a voyce also.

out a voyce.

CHAP. XXXVI.

Of the Epiglottis or After-tongue, and his Muscles.

That which the Grecians call *ἐπιγλωττίς* because it is set about the *glottis* or whistle of the *Larynx*, the Latins call *minor Lingua* or *Lingula fistula*, but because the *glottis* is also called *Lingula*, we haue rather called it the Aftertongue. It is a gristle and a couer of the cleft of the *larynx* made to fall vpon it when we swallow, that nothing should slip aside into the weazon [tab. 17, it is placed betweene the first and second figure, but inuerted and was cut away from fig. 1, at aa, but tab. 15, fig. 4, 5, 6, b.]

Hippocrates
callet it.
claustrum the
locke or thaspe
What it is.

Aristotle in the twelfth Chapter of his second Booke *De Historia Animalium*, thinketh that all creatures which lay Egges doe want this *Epiglottis*, but doe close exquisitely or dilate againe the top of the *Larynx* as they please to keepe any thing out of their longues without any use of such a couer as is necessary in other creatures. *Placentinus* addeth that Frogs haue none of it.

It is seated betweene the *Larynx* and the tongue, and if you looke vpon the superficies of the membrane that compasseth the tongue which is continuall with this *Epiglottis*, it may be esteemed to be as it were a part of the tongue: whereupon some haue thought that it hath his originall from the roote of the tongue, whereas it is more likely that it arises from the *Shield-gristle*. For it ariseth vpward with a large Basis recurued forward from the inward and higher part of the *Shield-gristle*; [tab. 15, fig. 4, *, fig. 5, +] afterward it grows broder a little and a little, & becometh like a round Arch, but in brute beasts it is by degrees angustated & determineth into a broad and sharpe edge. In the Basis thereof it is tyed to the *Shield-gristle*, all the rest of it is loose and hangs at liberty.

The situation
Connection.

The forme as saith *Hippocrates* in his 14. Book *de morbis*, is like the luy leafe, for the Basis is broad and arched forward into a roundnesse, or it is like a little tongue as *Pliny* & *Celsus* write. *Vesalius* compares it to a triangle. *Columbus* to a little shield curued and straightened toward the edge. *Aquapendens* to a triangle which hath crooked sides.

The forme.

The vpper part called the backe which is next vnto the palate, is a little conuex & buncheth outward, the lower side which is next to the cleft or whistle is hollow or a little concuous. The breadth of it is not only enough to couer the cleft but to spare.

It is also of it owne Nature rigid and stiffe standing, that the pipe of the rough artery might remaine open, least the heart should be suffocated; yet is it flexible that it might perfectly shut vp the cleft ouer which it is disposed: beside, if it had not beene flexible the waight of the meat and drinke would not haue depressed it in the swallowing: againe, if it had not been stiffe and rigid, when it is once borne downe vpon the cleft in the swallowing of meate, it would not haue started vp againe to giue way for the yssue of the breath. Wherefore the substance of it is gristly and thin, somewhat softer then the other gristles, yet so, that it is softer, thinner and more flexible on that side that respecteth the palate, especially in the very end nere the gullet it is very soft, and couered with a fat membrane. For when the creature breatheth it is lift vp of it own accord to make way for the ayre, but when he swalloweth it coucheth vpon the *Larynx* least the meate should fall into the Lungs.

Rigid or stiffe.

Yet soft too.

For

The reason thereof.

For that which is swallowed (as *Galen* well hath written in the 16. chap. of his 7. Booke *de usu partium*) falleth 1. vpon the roots of this Astertongue, after it is carried vpon the backe of it which maketh it to cough or incline. These motions this *Epiglottis* could not haue had if it had bin eyther membranous or fleshy, because it would haue alwayes lien depressed, or being once depressed it would hardly haue beene raised vp againe, neuer erected vpright. Neyther could it haue beene bony, for then it would alwayes haue bin rigid, neyther could it haue bin depressed with the swallowing of meats and drinks. Wherefore with *Galen* wee think that the motion of the *Epiglottis* or Astertongue in a man is naturall, and that the cleft is couered and againe vncouered, not by the helpe of muscles but by the waight of those things which we eate and drinke.

The motion of it in men. Naturall.

In some beastes voluntary.

But in Beastes that chew the Cud there are some muscles found, as we shall say in the History of the Muscles and shew them somewhat particularly, because it is an ordinary thing for yong practitioners in Anatomy, to exercise themselves in dissecting of the Throates of Oxen and such like: But in the meane time wee must remember that the *Epiglottis* is couered ouer with a fat membrane much like to the nature of a ligament, which at the *Shield-gristle* is full of fat.

The vse of the *Epiglottis*.

The vse of the *Epiglottis* is to couer the *glottis* or whistle when we swallow our meate, for if at vnawares any of the meate do slip into the wezon, we presently keake and are near strangling till by coughing it be gotten vp againe, the reason is, because that which descendeth taketh away respiration. So *Anacreon* the Poet was strangled with the stone of a Reysen. And *Fabius* the Senator drinking a cup of Milke was choaked with a haire that was therein.

Part of the drinke gets into the wezon.

An instance.

The vse of peritorall Medicines.

Alexander Benedictus tells of a woman who would haue giuen her Son a Pill and was constrained to thrust it downe his throate with her finger, she thrust it into his wezon & he died instantly. Because therefore a man cannot liue without Respiration, when that Respiration is interrupted Nature rowseth vp her selfe to make resistance, and so we straine at the least crum that fals the wrong way. Yet wee must not imagine that the cleft is so exquisitely closed but that some part of the drinke slipperth into the rough artery, gliding downe by the side of the *glottis* though it be not felt. And this way we thinke distillations doe yssue out of the head into the Lungs, which though they be very abundant yet he that is sicke cannot feele them, especially in sleepe they gather very fast together. How *Hippoc.* proued that a part of the drinke is conuayed vnto the Lungs, we haue before shewed by the cutting of a Hogs throate instantly after he had drunk water colored with Vermilion or any such like, for you shall finde the very colour in his wezon. Again, if some of the drinke did not slip downe by the sides of the rough artery, it were in vaine to prescribe Eclegmes, Syrups or Lozenges in affects of the chest. But we finde by experience that all these doe helpe expectoration and make the spittle come vp more roundly, if they be taken by little and little the head reclined backward, licked off a knife, a Liquerize stick or such like, or if the Lozenges be conteyned in the mouth till they melt of themselves and passe insensibly into the *Larinx*. And heerein we imitate *Galen* in the 7. chap. of the 4. Booke of his method, where being to cure one that had an Vlcer on the inside of the rough artery, caused the Patient to lye vpon his backe, and a moyst Medicine that was fit for the Vlcer to be giuen and to be held in the mouth as long as he could, and to relax and remit the muscles of the place, for so saith *Galen* by little and little some of the Medicine will distill into the artery.

Tab. 17, fig. 1. sheweth the *Larinx*, hauing the *shield-gristle* cut into 2. parts, but one part of it together with the *Epiglottis* is innerted, as by the Letters may be perceined. Fig. 2. exhibiteth the *Larinx* shewing the *glottis*.

But

But the reason why water or drinke when it falleth into the weazon causeth a cough is, because as *Hippocrates* saith it maketh a disturbance for that it opposeth the respiration. For the liquor that falleth down by the sides of the arteries, doth not withstand the egress of the aer, rather it furthereth it by making the way moyst & slippery. Hence we may see how ignorant the Ancients were in Anatomy, as *Plato*, *Philistones*, *Dioxippus*, and such like, who conceived that the drinke went into the artery or weazon, and so into the Lungs, and the meate through the gullet into the stomach. Against this opinion *Hippocrates* disputeth in his 4. Booke *de morbis*, that is, against those that think the drinke falleth into the Lungs, yet he doth not deny but some drinke sipeth that way as we haue said before. Wherefore (saith *Galen* in the 9. chap. of his 8. Booke *de Placitis*) if *Plato* thought that all the drinke was conueyed into the Lungs hee cannot be excused because his ignorance is euen palpable: but if he thinke that a part of the drinke is deriued into them he is not altogether deceived.

Why we cough
when any
thing falls into
the weazon.

The like we may say of *Aristotle*, who thought it an error to say that the drink passed into the Artery because there is no thorough passage for it, as there is out of the stomacke into the draught. For verily if that be auouched of all the drinke it is a very absurd conceit: but if it be meant of a little it seemeth to be true.

Aristotle.

Another vse of the *Epiglottis* or after-tong is to strike the aer which ariseth from the Lungs into a tuneablenesse, especially if it arise with a force or impetuous violence thereunto. And this vse we haue out of *Laurentius*.

Another vse.

CHAP. XXXVII.

Of the Membrane of the Larynx or Throate which is the Ligament thereof.

THe Larynx is bound about with a Membrane which is common with the membrane of the mouth, to be a defence to it both outwardly and inwardly, and whereby the ayre being gently and easily stricken, might make the voyce pleasant and moderate. First inwardly, the whole cavity is compassed and so it is led ouerthwartly to the vpper part of the Larynx, being diuided in the middest of his length it maketh a little cleft. But outwardly it doth partly encompassse the external superficies, and partly it inuesteth inwardly the gristles and muscles.

The membrane
of the Larynx.

They are steeped in a certaine slimy humidity, partly least the Respiration being warme, smoky and dry, should make the parts dry also, partly that the *Epiglottis* might be closely ioynd to the glottis and so his exiccation might be hindred, which humidity is more abundant within, yet so that in those which are found it is neither more copious nor more scarce then the Instrument of the voyce doth require; by it also it is polished and so the voyce is made pleasant and equall, for being moystned with a kind of humidity it doth familiarly beate the ayre, whence the sweetnesse of the voyce proceedeth. This may be prooued by the example of Musicians, who going about to sound longer Pipes or Trumpets whether they be of Brasse of Wood, will somewhat moysten them (haply with their spittle) whereby the voyce may bee more delectable, else because of too much siccity the sound is not onely vnpleasant and harsh, but is made with more difficulty and labour; like as if it bee too moyst the sound is obtruse, wherefore wee said before the voyce is made hoarse by the humors which come out of the Braine into the Choppes.

Why the mem-
branes of the
Larynx are
moyst.

Whence a
pleasant voyce
proceedeth.

These Membranes of the Larynx are for the most part thicker and stronger then all the rest. The outward is very crasse and lax and as it were rough and rugous, for aboue the *Epiglottis* it is lax and crasse, where it is bound to the sides of the 3. gristle, and betwixt it and the gristle, especially at the basis, there is a little Fat growing. It is lax, that it may more easily bee incurued and turned vpon the Larynx and be moued in deglutition or swallowing, in an acute and graue voyce vpperward and downward. And it is crasse, somewhat hard also and dense, because by that way meate sometimes halfe chewed, hard and in great gobbits must passe of necessity.

Why they are
crasse & thick.

Why they are
lax.

Some there be which thinke that this Membrane is increased with fleshy fibres, and that it becommeth a muscous membrane both in men and beasts to helpe the lifting vp of the *Epiglottis*, which Fibres are compassed with a little skin both outward and aboue, least it should be hurt in the passage of the meate.

The

The Inner
coate.

The internall Coate or Membrane which is more crasse in the cavity of the Larynx or Throtle then it is in the pipe of the artery, is soft, stretched and slippery, because the cavity was to be made polished and smooth; but where the cleft of the Larynx doth close, this membrane on both sides is by often compressing of it when we hold our breath, made more hard and callous, & with the substance doth change the colour and waxeth more white. But of this Membrane wee haue spoken somewhat before in our History of the Rough Artery. Concerning the vessels also and the Glandules of the Larynx wee shall speake in their proper places.

CHAP. XXXVIII.

Of the Sound and the Voyce.

IT is sufficiently manifest by that which we haue sayd, that the voyce is an action of the Larynx, and that it is the Instrument of the voyce, and that the *glottis* or whistle is the first and immediate cause of the voyce; and this is *Galen's* opinion, wherefore we will discourse a litle of the voyce.

How a voice
is made.

The voyce therefore according to *Aristotle* is a certaine significative sound of a liuing creature, or as *Galen* defines it, the voyce is the aire stricken, and a sound is the percussion of one body against another in some other. There be therefore 3. things required to the effecting of a sound, to wit, two seuerall bodies which do mutually strike one another, and the ayre in which the percussion is made, which ayre is beaten and broken betwixt the two bodies.

What things
are required to
e sound.
The bodies
must be hard.

But that these bodies thus mutually knocking one another, may effect a sound, first, it is required that they be stretched, by which tension or stretching they are somewhat hardened, therefore *Aristotle* supposed that they ought to be hard, for a sponge and wool may mutually strike one another and yet no sound be made. But if you say that sounds are oftener made by hard bodies, yet it is true also that sometimes they are made by soft bodies, for if you ioyne your lips together a kind of whistling may be heard, but this proceedeth from their tension whereby they thrust out the ayre by compressing each other.

Broad and
plaine.
And polished
for the better
sound.

Moreouer they ought to haue a broad and plaine superficies, for two needles striking one another do make no sound. Again, the percussion ought to be vehement and quicke, for if you gently put your hand to any thing no sound is heard. But if besides, these bodies be polished and concauous or hollow, and of a solid and ayry matter, such as brasse and glasse is, then the sound will be greater, more plaine and delightfome, which may be shewed in bells and musicall Instruments, for such bodies containe a great deale of ayre in them, which aer when it is moued and seeketh a vent, doth euery way strike about the sides & euery way causeth a resonance or resounding.

What is requi-
red to a voyce.

Now seeing a voyce is the sound of a liuing creature, or a certaine species or kind of sound; there must be euen so many things required to it as to a sound, Namely the aire for the matter, the bodies which by compressing the ayre doe as it were breake it for the efficient cause; and we may adde the place which is the head of the rough artery.

The aire expi-
red:

The ayre which is required for the forming of a voyce is that which we returne by expiration, and this is the matter for the generating of a voyce; for that which is inspired is prepared for the refreshing and nourishment of the heart and Inbred heate. Wherefore a mans voyce is so long continued as the expiration endureth, and when it fayleth the voyce vterly ceaseth. Now this expired ayre is broken by the ayry Instrument and so the voyce is formed at this breaking, and where it is broken there percussion doth forthwith follow. But it may be demanded which of the ayry Instruments can strike and presse this ayre.

By which of
the spirituall
Instruments
the ayre is
broken.

The chest and the lungs do not make this voyce, because their motions be *Diastole* and *Systole* or dilatation and constriction which make no voyce. Neyther is it the pipe of the Rough artery or the greatest part of the weazon, because it wanteth muscles: wherefore it cannot perfect the voyce which is a voluntary worke.

It is broken by
the throtle and
why.

Moreouer, if you cut the weazon below the larynx or head, the creature wil yet expire freely, but he will not vter any voyce: and if againe you bind this incision the voyce will returne. Neyther is it the Nosthrils which is the cause of the voyce, because they are only passage, nor the mouth because it is onely a receptacle, nor the tong because they which be dumbe haue their tongs & respiration sound; so they which haue their tong cut out do yet vter some kind of

of voyce. It remaineth therefore that amongst the ayry instruments only the Larinx or throtle is it which is, as it were, the shop or worke-houle wherein the percussion is made, which the fabricke and structure of it do sufficiently shew.

For it hath muscles which are necessarily required to the effecting of a voyce which is a voluntary action: It hath also nerues which afford the motion, gristles also which are hard bodies, broad smooth, polished and concauous or hollow, vpon which the aire may easily bee broken, constringed and compressed and therewithall rebound. It hath also a cleft which is requisite vnto the breaking of the aire that so a sound may be made. For this breaking of the aire cannot be done vnlesse it passe through by some straight and narrow way.

This Elision or breaking is made through the cleft when it is constringed and angustated or straightned by the articulation of the *Arytenoides* or Ewre-gristle and the muscles. Wherefore *Galen* writeth that a voyce canot be made vnles the passage be strait, neyther can that passage be wel called straight, vnlesse it tendeth by litle & litle from a large passage vnto a straighter and is againe amplified or enlarged from that straightnes. After this breaking doth a percussion presently follow, cyther against the ayre or against a solid body, and therefore *Galen* supposeth that the *Vuula* is like the quill of a Cittern in the forming of the voyce, because the aer being blown out is forced against the *Vuula*.

How this ayre is broken.

But not onely the straitnesse of the cleft is necessary vnto the voyce that the passage of the ayre be narrow, but also the vehement impulsion of the breath, so that it suddainly and at once breake forth: for when eyther of these faile the voyce cannot bee made; which sudden and vehement expiration *Galen* calleth *expiratio* or efflation. The other cause therefore of the voice is efflation without which it cannot bee made, though there may be efflation without any voyce.

Vehement impulsion of the ayre is required vnto the sound

This exsufflation or strong breathing out is made by the muscles, binding the Chest and the *Abdomen* or panch, by which constriction the Lungs are depressed and constringed, the *Midriff* is incurued towards the cavity of the chest, whereby his cavity is made straiter and the breath carried vpward out of the Lungs thorough the rough artery, (wherefore *Galen* said, that the voice was prepared in the rough artery when the aire being shut vp and compressed there, doth after a sort attaine the state and condition of a solid body before it issue through the cleft) and being extruded or thrust out with violence and force through the strait cleft, yeeldeth that sound which we call a Voyce.

How exsufflation is made.

Galen expresseth the vse of the voyce in these words, that it is the Messenger of the thought of the minde, and therefore worthily is accounted the principall of all the actions of the Soule.

The vse of the voyce.

And thus are wee arriued at the end of this Booke of the Senses wherein wee haue omitted the Sense of Touching because it is already handled in the second Booke. Now wee come vnto the Controuerfies.

A Dilucidation or Exposition of the Controuersies belonging to the Senses and their Instruments, as also of the voyce.

*Iulius Casserius Placentinus his Præface, translated by a
Gentleman, who desired it might bee keere
inserted.*

Of the Excellency of the Senses.

The contem-
plation of our
felues doth
further vs in
the knowledg
of God.

When I compare Diuine things with Humane and in like maner Humane with Diuine, and with a through examination doe diligently view the properties of them both; I can finde no man so neere a kin to the Nature of God, as those which make good vse of that Oracle of *Apello*, *γνῶθι σεαυτόν*, *Know thy Selfe*. For seeing that admirable Archite& maker of all things did make man according to his owne Image, it cannot be but he which is well skilled in the Fabricke and Workman-shippe of himselfe, vnto him I say will the Nature of the Creator and Arche-type more plainly appere, because hee which is well read in his owne body, shall see in all euen the least operations of his minde or actions of his body a liuely impressiō and infallible markes of Diuinity. And hence it was that they which vsed no diligence to pry into the structure of their owne bodies, were worthily reproached by the Ancient with the ignominious Tittle of *Epicurean Hogges*, for such men being ensnared with the allurements of their Senses, were onely carried thither, whither like Beastes they were transported by the force and rage of their senses, measuring the chiefe felicity of man by the narrow scantling and naked pleasure of the body. But *Ouid* doth manifestly shew how farre a man differs from a Beast where hee singeth,

*Pronaque cum spectent animalia cætera terram,
Os Homini sublimè dedit, calumque tueri
Iussit, & erectos ad sidera tollere vultus.*

When other creatures on the earth do pore,
Nature gaue man a high erected looke:
The Heauens to view, and Dicties to adore,
And read the Characters in that faire Booke.

Why beafts
looke downe
and men vp-
ward:

Surely a hidden mystery of a Poet, and words truly befeeming a man, wherein he would intimate nothing but this, that man being mindfull of his Diuine originall, may by the contem- plation of himselfe ascend higher into the mysticall knowledge of his Diuine Creator. Seeing therefore it is a matter of so great moment to know our felues: It seemeth to mee not onely commodious, but of absolute necessity to compose some smal Treatise (though a taske of hard labour) wherein as in a most cleare glasse a man may take view of himselfe, and see his owne nature as it were deciphered with *Apelles* Pencill. Wherefore I will here exhibite both the essentiall parts of man, to wit, his Matter and Forme, together with their functions and pro- prieties, as well particular as common, obseruing the order of Nature, because wee cannot come perfectly vnto the knowledge of man, vnlesse first wee doe well see into the Essence both of the body and the soule. Now the knowledge of the soule cannot bee made manifest but onely by her operations, which also seeing she doth not performe without the helpe of corporall organs, there is a necessity imposed, that we also vnderstand the exact composition of the body. But because in the deliery of the method of Arts we ought alwayes to proceed from vniuersals and such as are better knowne vnto vs, vnto particulars, and that the faculty of sensation is as it were an vniuersall thing, as being disperfed through the whole Systeme and frame of the body, the order of Nature requireth that I treat of it in the first place.

Why he first
treateth of the
Senses:

More-

Moreouer, amongst all the offices of the Soule, this facultie of sensation seemeth to challenge the chiefe place; neither that facultie onely which is lodged within and receiue the Images of things, and after deliberation or discourse doth iudge of them; but much more that whole set of Sences which doe outwardly *perceiue* all sensible objects, and perceived, doe carrie them to the Tribunall of the internall Sense and doe so informe it, that it is able to pronounce a true iudgement concerning them. For without these externall Sences, we must needs acknowledge the Internall imperfect and vnprofitable. For if we conceiue any thing in our minds and nourish that conceit by discourse, againe and againe ventilating it to and fro, we shall obserue that all things had their originall from the outward Sences; for neither could Colours, Odours, nor Sauours be knowne, neither could the internall Sense discourse of Sounds, or of any Tactile qualities without the message (as it were) and information of the outward Sences, by which the Images of things are imprinted in it. And with this doth that Philosophicall Axiome agree. *Nihil est in intellectu quod non prius fuerit in sensu. Nothing is in the Understanding which was not before in the Sense.* The Prince of Philosophers esteemeth this the Fountaine of all Arts and Sciences. And surely if any Man setting aside the assurance and the authoritie of Senses, shall seeke for the grounds and *endences* of Arts and other Objects else-where, he shall not onely entertaine into his mind a dissolute and vaine confusion, tossed hither and thither without any stedfastnesse, but also calling in question the most sure Foundations of Nature, shall cast himselfe headlong into a Dungeon of perpetuall and intricate obscuritie.

All Arts haue
their beginning
from Sense.

*Quid referemus enim quod nobis certius ipsis
Sensibus esse potest; quo vera & falsa notamus?*

For what more certaine evidence of things can be obtained,
Then that which true or false we iudge by outward Sense vnsained?

Whence shall he haue the grounds of Demonstration which endeauoureth to derogate from the credit which is due vnto the Senses, which are the Foundations of all Sciences? For Demonstration is from vniuersall things, and such vniuersals doe arise and spring out of singulars: But the externall Senses doe *perceiue* all singular things. Now there is none so ignorant who doth not see what will follow hence. The same thing *Lucretius* confirms in these Verses.

Demonstra-
tion from
Sense

*Iunenes primis a sensibus esse creatam
Notitiam veri, nec sensus posse refelli,
Qui nisi sunt veri, ratio quoque falsa sit omnis.*

The knowledge of all truth (who seekes) must hold
From outward Sences first to haue proceeded
Those Demonstrations cannot be controld,
Or could they, Reason's selfe should be deceived.

Hence it is, saith *Aristotle*, that such Men are vnfit for some Arts and Sciences, to whom Nature hath from their birth denied any of these Senses.

Whosoever therefore doth not content himselfe with the infallible credit of the Senses, is worthy with *Anaxagoras* (who called into question the whiteneffe of the Snow, as *Aristotle* remembreth of him) to be giuen ouer vnto the doubtfull and suspended vncertaintie of the *Pirrhonij* or Sceptickes; and to wait till the things themselves should tell him what their seuerall natures are. But we in the meane time admiring this maiestie and certaintie of the Senses, will make entrance into so faire and pleasant a Field of Discourse, and handle euerie one of them in particular, beginning with the Sense of Touching, which as it is more common then the rest, so without doubt it deserues the first place: For this is the ground of all the rest, and doth consist in the *εὐπαρέα*, or moderation and temperament of the foure Primarie qualities. And hence it was that *Aristotle* (and with him all other Philosophers) haue iudged this Sense worthy that honour to be called *κατ' ἐξ ἑνός*, or by a certaine eminency or excellency without adding thereto any Epithite, *The Sense*; as if they should haue said, the onely Sense of all Senses. And that not vnworthily; seeing (as the same *Aristotle* affirmeth) euerie Sense is a kind of Touching, as whereof the whole company and set of the other Senses doe stand in need for the better perception of their objects. As for example: The Taste neuer should discerne of saviours except the Gustible matter were touched by the spongy body or Pulpe of the Tongue: Neither could the Organ of Smelling receiue any

The dignitie
of the Sense
of Touching

No Sense
without
Touching

Odours vnlesse the perfume of odoriferous things should touch the same. The same are we to thinke of the other Senses, to which in like manner is required, though not a Mathematicall yet a Physicall Touching: What need we add more? It is the Sense of Touching, which perfecteth the operations of all the other Senses, and yet it selfe needeth not the helpe of any. Yet this I add moreouer, that this Sense is capable of the nature of many more contraries then the other Senses, for it iudgeth of heat and cold, moyst and dry, soft and hard, light and heauy, slender and grosse, rare and dense, smoothe and rough, and an infinite number of that kind. On the contrarie, the Sight doth perceiue nothing but white and blacke; for red, yellow, sky-coloured, and other such like, are not contrarie but intermediate colours, and so of the rest. I may also lightly passe by this, that all other Senses are restrayned within some small Organ about the Braine, but the Touching is diffused through the whole Body.

Conception
is by Touch

These Arguments doe sufficiently commend the preheminance of this Sense of Touching. Yet if you please to attend, and more accurately consider those which follow, you shall see the maiestie thereof to shine more plainly vnto you. For first, it is by the benefit of Touching that we are conceiued and formed in the fertile Garden of our Mothers Wombe. For wise and prouident Nature ayming at Eternitie, hath endued the parts of Generation with a most exquisite Sense of Touching, for the conseruation of the Species or kinds of Creatures, so that the Creatures being rauished with an incredible kind of pleasure, doe more readily apply themselves to Venereall embracements (otherwise a thing rather irksome then to be desired) and endeaour the procreation of their owne kinds. When the Infant in the Wombe yet liueth onely a vegetatiue life, he is first of all endued with the Sense of Touching; whereby he is cherished, nourished, encreased, and at length perfected; for so long as he is in the Prison of the Wombe, he neither seeth, nor heareth, nor smelleth, nor tasteth any thing, but yet hath absolute necessitie of the Sense of Touching, that he may be able to auoid imminent dangers.

The Touch
doth first
exist of all
Senses

Moreouer, this Sense is not onely borne together with vs, but also (which is more worthy of admiration) when all the other Senses perish, or are suspended vpon small perturbations of the Mind, and leaue vs vngarded and prostituted vnto Death; yet this, like vnseparable and faithfull *Achates*, doth attend vs vnto the last breath: whence *Aristotle* in the third Book *De Anima*, Cap. 13. Text. 67. writeth, *That if any Creature be deprived of this Sense of Touching Death will of necessitie ensue. For neither is it possible (saith he) that any Creature should want this Sense, neither to the being of a Creature is it of absolute necessitie that he haue any Sense besides this*; As if he should say, that this Sense is of the verie Essence of the Creature; and therefore other sensible objects by their immoderate extreames, doe onely corrupt their proper Organ, but the excessiue qualities of tactile things doe take away the life it selfe. Againe, things euen without life cannot subsist without Touching, as *Aristotle* saith, who thought that neither action, nor passion, nor any mixtion can be without Touch, & therefore neither can the *mixt body* be without it. For though those things without life doe draw their nourishment out of the Earth, yet they doe it not indifferently and without choyce of that which is more or lesse pleasant vnto them, if at least this kind of naturall accord may be called a pleasure, which is nothing else but a power to separate or distinguish that which is conuenient, from that which is inconuenient.

Touch is of
necessitie,
the rest for
commoditie

Plants cannot
be without
Touch

Furthermore, if we will stand to *Aristotles* determination, that there can no other Sense subsist without Touching, then will it follow that this being taken away, no Sense can remaine. Now if the Senses be taken away, the whole Family of Arts (which we said before did depend vpon their credit) must needs decay, nay you shall remoue the Sunne it selfe out of the World. If any Man doubt of this, let him seriously suruey all the Arts both Liberall and Mechanicall.

The vse of
Touching for
Physicke

If you further demand what vse this Sense doth afford vnto Physicke, know that without it this Art would be verie defectiue, yea would so darken the Eyes of Physitians, that they shall not be able to determine any thing certainly concerning the temperature of their Patients, or of their Faculties or strength; but must of necessitie grope vncertainly in darke and palpable ignorance.

His profit in
morall Phi-
losophy

If you respect Morall Philosophy, this Sense will stand vs in great stead. For perceiuing and feeling the euils which ensue of Vices it doth lead and encline vs vnto the way of Vertue; yea it causeth vs to take pleasure therein, which pleasure the Epicures doubted not to account the *Summum Bonum*. The like we might say of other Arts, which (least our

Discourse

Discourse should be without end) we will with silence passe by, in all which Touching is not without his excellent vse.

To conclude, If it be lawfull to transcend from these Earthly things vnto Celestiall, we will a little consider what vse this Touching hath in Diuinitie. Did not this Sense reduce *S^t Thomas* wandring in by-ways out of the heavenly light into the true way, when he would try the presence of our Sauour by this Sense as it were contemning the vse of the rest? Did not the Woman onely by the Touch of the Hem of Christs Garment become sound and cured of her twelue yeeres Flux of Blood? And doe not we read that eternall Prince of Physitians restored sight vnto the Blind onely by the Touch of their Eyes? And did he not heale the Woman sicke of a Feauer by Touching of her? Yea, and that which is beyond all admiration and farre exceedeth the vnderstanding & capacitie of Man, did he not bring againe from Death vnto Life the Daughter of *Jairus* by taking her by the Hand? And the Sonne of the Widdow ready to be committed to the Earth onely by Touching the Coffin? O healthfull and sauing Touch! O searching Sense! But we hold our Hands, both Time and the Matter requires that we prosecute the remaining Senses in as few words as we can.

After the Sense of Touching we place the Taft in the second ranke. For besides that one kind of Obiect, to wit, Earthy, is by Philolophers assigned as common to them both, it is as well as the Touch not onely commodious (for so are the other subsequent Senses) but also necessarie vnto the conseruation of the *Individuum*, whence it is that many commendations of the Touch doe not vnfitly agree vnto the Taft. For seeing Taft is the chiefe Sense in discerning of Savors (as all Men of vnderstanding acknowledge and experience it selfe confirmeth) it must needs follow that by the helpe thereof the Body is nourished without danger, but when it failes the Body perisheth & the whole nature thereof goeth to nothing. For without it we cannot discerne of Savors, nor iudge betwixt hurtfull things & healthfull, neither betweene that which is pleasant and vnpleasant, but become inferiour not only to brute Beasts, but also to Plants, which doe not confusedly and without choyce, attract any Aliment but that which is most agreeable to their Nature, and so conuert it into their owne Substance.

But because the Sense of Tasting doth participate with the Touch in the perception of sweetnesse & pleasantnesse as in many other things it doth: Therefore I suppose the worth or excellency thereof is sufficiently declared in the commendation of the Sense of Touching, so that we thinke it vnnesse to vse any longer discourse thereof.

We will now proceed to the Sense of Smelling, the Organ whereof seeing Nature hath placed in the middle of the other Senses, we will therefore ascribe vnto it the middle place of honour between the other Senses. This Sense doth not onely receiue the fragrant breath vapouring from odoriferous Obiects, and abiding in the Aire; but is besides a faithfull Taster of Meats, it gouernes the Mouth least some-times at vnawares we should swallow that which is hurtfull and distasting, and so pollute the sweet Balsame of our Life. And this instinct we see in Dogges and Apes, who neuer snatch any thing into their Mouthes before they haue first made tryall thereof with their Nose.

Againe, by the strength of this Sense many Creatures doe hunt out their liuing, and therefore the Kites follow after Karkasses, Hounds after Hares onely by their sauers: I say nothing of that profit which it affords to the Art of Physicke: For among other predictions in our Art, that is not the least which is taken from the Sauour of the Patients Sweat and other Excrements, whereby oftentimes we find out the cause, the kind, and the issue of the Disease. Chirurgians also by the Sauour or Smell of a Wound are able to iudge whether it be *Cacoeticum*, that is, of an ill and vntoward disposition or no. Add hereto that by the Smell we attaine to the knowledge of Simples, yea and of Compositions, with what faculties and vertues they are endowed. From hence some haue concluded that all odoriferous things are hot, and such like Propositions and Paradoxes.

The beautie that is added to the Face of Man by this Organ of Smelling (we meane the Nose) is verie great: I will giue you a pregnant instance thereof in an example or two worth our remembrance. First, of a young Man who being adiudged to be hanged, and the Executioner at hand, a certaine Mayd suborned by his Friends, and quaintly dressed and set out, goes vnto the Iudges and makes supplication for his life, requiring him for her Husband; well, she ouercame the Iudges: This done, the guiltie young Man being set at libertie and comming from the Gallowes vnto the Mayd attired and dressed in costly Ornaments,

The Nose
doth much
beautifie the
Face.

he presently cast his Eye vpon her Nose which indeed was verie deformed, and instantly cryes out, That he had rather haue beene hanged then freed vpon condition of vndergoing so deformed a choyce in his Matrimony. To this is that of *Horace* verie answerable in *Arte Poetica*.

Hunc ego me, siquid componere curem,

Non magis esse velim, quam prauo vivere Naso:

Should I indite, I had as lief my Nose should stand awry,
As fairely to begin my worke, and patch't vp bunglerly.

A Historic.

It is also a very memorable example (for we may mingle things thus holy with profane) which we read in our English Chronicles concerning one *Ebba* an Abbess in a certaine Nunry, who cut off her owne Nose and the Noses of her Nunnes, that being so deformed they might auoyd the hatefull lust of the *Danes*; taking it for granted, that the Nose was the chiefe ornament of the Face. And hence it was that in ancient time, when they would put Men to great disgrace and ignominie, or disappoint them of all hope of attaining to any degree of honour, or the gouernment of a State; they cut off their Eares and Noses. Yea those which had such deformed Noses were neither admitted to any Priestly function nor Imperiall Office. So farre was it from them to account them worthy honour, who were destitute of this honourable Organ. Hence it was that the Prince of Poets, *Virgil*, in the sixth of his *Aeneids*, doth call the cutting off *Deiphobus* his Nose, *Vulnus in honestum*, a wound full of shame and reproach. To these we may add, that the Nose is necessarie for our verie life, because Nature hath made it the Instrument of Respiration, without which we cannot liue one moment; for when the Lungs needs more Aire then ordinarie, we perceiue the sides of the Nose-thrills to be moued, some-times not without violence.

The Nose is
necessarie to
life.

The wonder-
full frame of
the Eare.

But passing by a whole troope of these commendations of the Sense of Smelling, we will proceed vnto the Hearing, which no Voyce, no not a Riuer of Eloquence is able to extoll with due prayes, if we doe but contemplate the cunning, skill and diligence, which Nature hath vsed in the Fabricke of this Organ, and more accurately intend how many winding Conuolutions, Burrowes, Holes, Shells, Dennes, and darke Caues like Labyrinthes she hath prepared and furnished therein.

Hearing is the
gate of the
Mind.

I add further, that by the benefit of the Eare we attaine vnto the knowledge of all kinds of Sciences: In respect of which, *Tully* doth equallize vs with the Gods. For these Arts are not ingrafted in vs by Nature, but to be obtained otherwise; for saith *Lactantius*, it is the propertie of God and not of Man to haue *proper knowledge*, that is, arising out of himselfe. For this cause Nature hath by a diuine Skill, made the Eares open, that we might alwayes heare when learned Men should teach and discourse learnedly, and lay vp in the Register of our Minds that which we haue heard. And hence it was that *Constantine* called Hearing the *Doore of the Mind*, because hereby we enter into the knowledge of other Mens conceits, and whatsoever is concluded within their Braynes, as it were, vnlocked and layd open by this Sense of Hearing vnto others. But some will haply say, that we may attaine vnto knowledge by Reading without any helpe of Hearing. We answer, that no Man knowes how to read which hath not first learned it by the meanes of Hearing. I will omit that which is found by experience, that a liuing and audible voyce doth better instruct then the silent reading of Bookes, and that things heard make a deeper impression in the Mind then those which be onely read, and hence haply was *Pliny* brought to beleue the Memory had his place in the lowest part of the Eare. Others there are who doe call Hearing the Sense of Memory, whence in their *Hieroglyphickes* they were wont to decipher and paint Memory a Hand holding an Eare; I also passe this by, that Hearing is after a sort the spy of the Life and Manners, whereupon *Isocrates* desirous to try the towardnesse of a young Man whom he saw: *Speake* (saith he) *that I may see you*. And in holy VVrit, *Iob* commands that *they bend their Eares and see*: accounting for certaine, that Hearing is the very meanes of discerning and iudging of Mens minds.

Hearing is the
Sense of Me-
morie.

The prayse of
Sight.

But the desire I haue of breuitie commands me to abridge my discourse. There remains now of the externall Senses onely Sight, which if it be not superiour and aboue the precedent Senses in dignitie and honour, yet it is not a whit inferiour to any of them. I say in dignitie not in necessitie: For if thereby we esteeme their Prerogatiue, Sight must come behind: But if you respect the situation, the conformation and the vse of this Organ, you may pronounce it more worthy by many degrees then any of the other.

For

For the situation and place, it is in the most erected Region of the Head: Beside proud Nature, hath on euerie side bounded the Eyes with a concauous Valley. They haue a sphericall or round figure, which is no small argument of their excellencie, seeing Nature is neuer wont to vse this noble figure, but when she endeauours to effect some difficult or excellent worke. And for their vse we may thence easily inferre their preheminance, for beside that they watch for the safetie of the Creature, detecting things hurtfull, manifesting things profitable, and laying open the differences of all things which are contained in this large Vniuerse; they bring vs vnto the knowledge of all things, so that they alone are fit and sufficient for inuention and discouerie of Arts, and (which is the most of all) they doe make manifest the great Creator of all things by those things which are visible, in the knowledge of whom doth our chiefest happinesse consist. They therefore which be destitute of these most diuine Organs, may truly professe themselues miserable, seeing they remaining in perpetuall darkenesse, cannot admire and contemplate the workes of Almighty God, nor behold the infinite varietie of the kinds of things, neither yet dare euer affirme that they know any thing certainly, because of force they must beleue that which they Heare related to them by others.

That spirituell and most noble object of the Eye (I meane the Light which is the Queene of all qualities) who doth not admire? And hence also concludes the supremacie of this Sense; for the Eyes by the fruition of Light doe distinguish Life from Death. Doth not Hippocrates (the Pillar of Physicke) propound vnto vs most certaine signes of the passions of the Mind by the Eyes? By these as by Windowes we may pry into and penetrate the deepest & most secret conueyances of the Soule; and therefore Alexander not vnadvisedly said, that the Eyes were the *Looking-glasse of the Soule*, whereupon some famous Philosophers haue placed the chiefe seat of the Soule in the Eyes: For the Eyes doe burne and shine, they twinkle, they winke, they are sorrowfull, they laugh, they admire, they loue, they lust, they flatter, and in one word they decipher and paint the Image of the Mind with so artificiall a Pencill, that they seeme to be a second Soule; what shall we say more? Doth not Galen himselve so highly extoll this Organ, that he thought the Braine was onely framed for their sake, a part so necessarie and excellent, that it makes vs very much resemble the very diuine Nature? And doth he not moreouer write, that the whole Head had the highest place in the Body, onely because of the Eyes?

A commendation doubtlesse wonderfull, yet not more admirable then competent and worthily deserued. For being a Man of great and profound knowledge, he considered that the Eye was the true *Microcosme* or *Little world* in respect of their exact roundnesse and reuolutions: wherein besides the Membranes, which I dare boldly call the seuen Spheres of Heauen, there be also the foure Elements found.

That Fire is there, we will proue in a conuenient time and place. That there is Aire, who will deny which vnderstands with what plentie of Spirits they doe abound? As for Water who doth not see it in the Eye doth proue himselve more blind then a Beetle. All the other parts we will liken to the Earth.

If you looke vpon the *Pupilla* or Apple, shall not you see shining Starres, yea rather a beaming Sunne? Wherefore thou maist not vnsightly call the Eyes with the Poet, *τῶν ἡλίου πυλᾶς* *The Gates of the Sunne*. Shall you not perceiue here the diuers-coloured Raine-bow, framed with a seuen-fold Circle? Shall ye not also obserue Hayle and infinite other things, which doe most fully declare the excellencie of this Sense by themselues without any additament of our Oration.

But seeing, as Agellius saith, It is more blame-worthy to prayse a thing slightly and coldly, then earnestly to dispraise it, least we should seeme to preiudice the worth of so excellent workes of Nature, we will here make stay and addresse the small portion of our capacities vnto a more abstruse Contemplation concerning the Nature, Manner, Number, Order, Medium, Object, and Organs of all the Senses in Generall: afterwards we will descend vnto particulars.

QUEST. I.

What Sense is.

The definition
of Sense by
Aristotle.

I. Grammatic.

Al. Aphrod.

Simplicius
definitionAll Sense is
made with the
knowledge of
the object

¶ Auing by way of Preface set forth the excellencie of the Senses, we are to proceed vnto a more full Discourse of them, which that we may the better accomplish, before we assay their particular handling, we will take a Taste of them in generall, which may make way to the particulars, and may serue in stead of a Preamble, for the Readers better vnderstanding. First of all therefore, it is to be considered what *Sense* is. Aristotle in the second Booke *De Anima*, Text 12, saith, *That Sense is that which can receiue sensible Formes without any Matter*. But he seemeth to define Sense in *potentia* only or *power*, which haply he would insinuate by the word *potest* or *can*, especially, because this cannot be a true definition of *Sense* as it doth indeed and really *perceiue*; for a Glasse also doth receiue sensible formes without any materiall substance, and yet that perception is no Sense. Whence Ioh. Grammaticus vpon the 127 Text of the second Booke *De Anima*, saith, *To be able to perceiue is not onely to receiue Species or Formes without the Matter, but there is also requisite an Animall Facultie which is not in all things that receiue the Formes of sensible things without the Matter*; as if he had said, Euen as it is in Glasses.

But the Philosopher would shew what manner of perception was necessarie to Sense, that is to say, that it haue the act of perception; and how the object ought to be disposed; except by the word *perceiue* he vnderstood *discerning*, which words Philosophers doe sometimes promiscuously vse, as we may gather out of Alexander Aphrodisias, who vpon the third Booke of the Metaphysickes saith, *That Sense is an apprehension or discerning of present sensible things which are without the Sensorium or Organ*, and this is Sense in deed and act; for we are then said to *perceiue* when we discern the object, which Simplicius vpon the 155 Text of the third Booke *De Anima* hath well noted, defining Sense to be *A knowledge or discerning stirred up in the Organ, first receiuing his act from the sensible object*: So that Aristotle by receiuing vnderstood nothing but the knowledge or discerning of the Object. And the same definition he doth accurately and distinctly declare in the second Chapter and 138 Text of the third Booke *De Anima*, where he saith, *That the Instrument of euery Sense doth receiue the sensible object without any matter, and therefore the objects being remoued, there are in the Instruments of the Senses, Sensations and Imaginations*. What can be more euident? For how can the Sense of that Object remaine in the Organ when the Object is set aside, if it should onely receiue it without any act of discerning? Are we not taught the contrarie in Glasses, which because they onely receiue, but know or discern nothing, therefore presently as the Object is remoued, they loose the Image. We will therefore out of this which hath bene said, gather a most cleere and absolute definition of Sense on this manner, *That Sense is a knowledge or discerning of the Object receiued formally in the Organ*.

QUEST. II.

What Action is, and how Action and Vse doe differ.

What Action
isWhy action is
called an
Active motion

¶ Verroes verie worthily saith in the first Booke *De Anima*, and the 51 Text, that the first and chiefe consideration of Sense is, *whether it be to be accounted amongst the Active or Passive Vertues or Faculties of the Soule*, that is, *Whether it be accomplished by Action or Passion*, for he which is ignorant of this, can neuer attaine to the perfect knowledge of the manner of Sensation. Considering therefore of this matter by the counsell of Auerrhoes, I haue here determined for the more euident clearing of this Question, to declare what Action is, and also what Passion is.

Action therefore (which the Greekes call *ἐνέργεια*) is a certaine active motion, proceeding from any thing fit for action for the obtaining of some thing. It is called an *Active motion* by Galen in the first Chapter of his 17 Booke *De Vsu Partium*, and in many other places, and that not without good reason, seeing that there is as well an Active motion as a Passive motion. Many call that an Active motion which is performed by the proper nature of the thing, and of it selfe alone: And that Passive which is caused by some externall Agent. As for example: The

The walking of a Creature is an Actiue motion, in regard that it proceedeth from the proper and internall Facultie of the Creature. But the casting of a Stone vpward is a Passiue motion, because it is performed by another, and not by the proper internall principle. But because all motion made either by an internall or externall Agent, in relation to the Patient is Passiue, and in relation to the Agent cause is Actiue, therefore certainly the casting of a Stone ought no lesse to be iudged an Actiue motion, then the walking of a Creature, neither doth this deserue lesse the name of a Passiue motion, then that; for a Creature in walking doth suffer, else we must determine (which is more absurd) that there may be an Action without Passion.

What actiue -
internall mo-
tion is

But in my opinion the Logicians distinguishing Actiue motion from Passiue onely in some respects and not in deed, haue more truly said, that Actiue motion is that which proceedeth from the Agent for the effecting of some thing; and Passiue that which is receiued of the Patient to make alteration in it: wherefore both Action & Passion being in deed one motion, as it commeth from the Agent is an Action, and as it is receiued of the Patient is a Passion.

What W
not to be

What W
not to be

Action is
relative

How action
and passion
doe differ

It is added in the aboue-named definition, *from any thing fit to performe Action*, because euerie thing doth not produce an Action, but that which hath a disposition and fittest for the performance of that Action. This fittest or habitude vnto Action, called in Greeke *εὐχρησία* or an agilitie of vsing, *Galen* in the first Chapter of his 17 Booke *De Vsu Partium*, calleth *Vse*, which signification doth much differ from the word *Vse* taken for the act of vsing or for the handling & exercising of an Action, whereof *Cicero* speaketh in his *Topicks*. For *Galen* vnderstandeth by *Vse* an aptitude and disposition of the parts to performe an Action, which parts if they were composed by Nature without this fittest they could neuer performe any Action, and so they should haue beene made in vaine.

Divers accep-
tions of vse

This fittest in liuing Creatures consisteth in the Temperature of the Similar parts, and the Legitimate conformation of the Dissimilar, which doth comprehend the Figure, Magnitude, Site and Number of them. Therefore this due Temperament and Conformation, as it is fit for operation is vnderstood by the word *Vse*.

Wherein this
vse consisteth

Moreouer, this *Vse* is two-fold, Principall and Assistant. I call that Principall, by the help whereof the Agent doth principally performe and exercise his operation. The Assistant I call that which is as a Handmayd, to helpe and further that the Function be the better performed. Againe, this Principall is also two-fold. Not subordinate and subordinate. The Assisting *vse* is three-fold, First, that which doth truly helpe; that which doth conferue or keepe; and thirdly, that which addeth some ornament or beautie to the Action.

Vse is twofold

That which is *not subordinate*, doth accomplish a principall Action which is not inferiour to any other: But that is subordinate, for whose sake the Agent vndertakes an Action which is subordinate and preparatiue onely. That *Vse* or aptitude which doth onely helpe and conferue, may be seene in the Lids and Hayres of the Eyes. And *Galen* in the 13 Chapter of the 11 Booke *De Vsu Partium*, doth plainly affirme, that the ornament and beautie of the Action is to be referred vnto this helping or assisting Aptitude.

The vse not
subordinate.
The vse sub-
ordinate

But here ariseth a difficultie, which is not slightly to be ouer-passed; for if those things be true which we haue said as we professe them to be, it will necessarily follow that in liuing Creatures euerie Organ shall haue some *Vse*, in as much as there is no part in the Whole liuing Body which is not fit and disposed to operation after some of the fore-said wayes, as is taught in the first Chapter of the 17 Booke *De Vsu Partium*. But *Galen* seemeth to differ from himselfe and to contradict this Doctrine in the eighth Chapter of his Booke *De Morb. Diff.* where he saith, that some parts haue *Vse* onely and not Action: Some haue both *Vse* and Action: And others haue Action onely and not *Vse*.

Obiection.

But this knot may thus be vnloosed, and this contradiction reconciled, if we say, that to haue Action and *Vse* is affirmed as well of that which doth helpe, as of that which doth principally apply it selfe to the performance of the Action: So euerie part of the Body shall haue both Action and *Vse*; but so, as to *haue action* doth signifie that aptitude by which the Action is especially performed, and to *haue vse* that for whose sake, or by whose meanes the *Vse* and the Action is holpen and assisted. The Action therefore is principally from the parts, and the *Vse* they haue ouer-plus, that is, that aptitude and disposition whereby the principall Action is either perfected or conferued, or receiueh some additament of beautie and ornament.

Solution.

QUEST. III.

Of the end of Action.

What is the
end of action

The action is
lesse worthy
then his end

THE last part of the definition was, *for the obtaining of something*, that the profit and end of the Action might be intimated, which is the fruition of that where-vnto the Action is directed. This is after the Action in Generation and Constitution, but it is the first in dignitie and excellencie, as *Galen* declareth in the 13 Chapter of the 11 Booke *De Vsu Partium*. And as the fruition of any thing is the profit of the Action, so the Action is the profit of the Vse: So that (as *Galen* saith in the first Chapter of his 17 Booke *De Vsu Partium*) Those things which haue an vse for Action, haue a double profit propounded to themselves, that is, the Action it selfe which is the profit of the Vse, and the fruition which is the profit of the Action.

Question.

Here doth arise a most intricate difficultie to be resolu'd, for because (saith *Galen* in the 8 and 16 Chapters of his first Booke *De Vsu Partium*) There is required vnto the knowledge of the profit of the particulars, a precognition or fore-knowledge of the Action, I thinke we must distinguish betwixt the Action of the parts and the profit of them, and so it is false, that the Action is the profit of the parts or of their aptitude.

Solution.
To know the
action is two
wayes vnder-
stood

The Action of the Organs may be knowne two wayes, either vniuersally and abstracted from their Organ, so that the production of the Action may be made manifest without any consideration of the Organ: or it may be knowne as it hath relation to the Organ, that so it may be manifest by what meanes it proceeded from the Organ, & what euerie part did performe which is found in that Organ. Now *Galen* affirming that the Profit of particular things cannot be vnderstood vnlesse we accurately fore-know the Action, doth vnderstand by the name of Profit the *Action*, and so would signifie, that the particular Action ought to be vniuersally and abstractedly fore-knowne, that it may appeare by what meanes it comes from his Organ, & that the function of euerie particle which is found in that Organ (though neuer so small) may be knowne. And so it is not absurd, that the Action should minister knowledge to it selfe, and should be both more knowne and more obscure then it selfe.

The difference
betwixt vse
and profit

The Vse therefore of the parts and their Profit, doe differ as the words of *cause* and *effect*, though Vse doe also signifie Profit, whereby it is manifest that the one is more large in his signification then the other.

The difference
of a worke
and action

Moreouer, that thing vnto the fruition of which the Action doth aime, is either separated from the Action so that the Action ceasing it is abandoned, or else it doth onely consist and hath his being in *Fieri*, that is, whil' it is in motion, & this is called in Latine *opus*, in Greeke *ἔργον* *actionis*, the worke of the Action. *Galen* therefore in the first Booke *De Nat. Fac.* saith well, that the worke is distinguished from the Action & is an effect thereof as Blood, Flesh, a Nerue, or such like are the effects of the Action of the Liuer and of the Seed.

Sometimes by the name of *worke* we vnderstand the Action, for Concoction, Sanguification and distribution, are certaine *actions* and yet the *workes* of Nature also; but we must beware least we call all the workes of Nature Actions; for Flesh, a Nerue, and Bones are the workes of Nature, and yet no Actions of Nature.

QUEST. IIII.

How manifold Action is.

What is an
vniuersall
action

Alen in the first Chapter of his Booke *De Vtilitate Resp.* deuideth the Action of a liuing Body into an vniuersall and a particular. I call that an vniuersall Action which is perfected by the whole Body as by his proper Instrument, as are the life (which life *Aristotle* in the 10 of his *Ethickes*, Cap. 3. and *Galen* in the place aboue quoted say, is a kind of Action of the Creature) as also are those foure which do attend it:

What a parti-
cular action is

Retention, Concoction, Attraction and Expulsion. Particular Action I call that, which belongeth to some one part or Organ, for the profit and behoofe of the whole Body. But they are almost infinite, yet all allotted to their owne proper parts, & so mutually conioyned and with such concord that they doe all serue and helpe the operations of the whole, and doe all conspire and as it were with one consent suffer together. For great Organs as the Head, the Breast, the *Abdomen* or Panch, and the joints doe with all their functions immediately serue the

The consent
of the parts

the whole Body: and the lesser which are parts of these are also referred to the Action of the whole. As the Eye whose Action being wholly destinated to the safetie of the Creature is Sight, which Nature by the Christaline humor doth exercise; all the other parts of the Eye doe concur vnto the constitution thereof, and serue either as causes without which vision cannot be made as the Opticke Nerues doe; or as a cause of the better performance of this Sense as the Muscles and Coats; or lastly, as conseruing and defending causes, as the Eye-lids and the Eye-browes.

Some doe subdiuide a particular Action into a common or publike, and into a proper or priuate Action; and they call that common which is referred vnto the vse of the whole and not of any priuate part onely, as are those operations called Animall, to wit, going, apprehension, vision, hearing, smelling, tasting, touching, imagination, ratiocination and memorie. Amongst the naturall operations, chylickation or the action of the Stomacke changing the Meat into Chylus, Sanguification, Expulsion of the Excrements, the sucking of the Vrine out of the Veines by the Emulgents, Attraction of Seed, the conformation of the Infant, with many other. They call that a proper Action, which is addicted vnto one only part, such as they affirme to be retention, Concoction, Attraction & expulsion, which I haue comprehended in the number of vniuersall Actions, but they say they belong vnto the proper vse of the part.

What a common action is.

What a proper action is.

But this manner of distinguishing is not to be in euerie respect admitted in my opinion, because it doth much rather engender a confusion then further our vnderstanding, in that they confound a proper and particular action with an vniuersall. For why should that action which pertaines to the whole and is vniuersall and common to all the parts, be called proper and priuate? How shall it be allotted to one onely part? If that which they call common be assigned to one Organ, how is it said to be common? Yet if any Man shall say, that it is called common by accident, because it tends to a publike and common good, him I will not gain-say. But it will be obiected, that that which is called by them a proper & priuate action, will by the Physitians neuer be admitted to be vniuersall and an action of the whole Body, and of all the parts thereof. For although attraction, retention, concoction, expulsion, doe agree to the whole and to all the parts, yet they be so appropriated to their seuerall parts, that they seeme to be proper vnto euerie particular, because the seuerall parts doe conueniently exercise them by their owne nature. But I thinke, that attraction being restrained to some certaine humour, doth not enduce the proprietie of attraction, but of that which is attracted by it.

Obiection.

Solution.

Now that which is drawne, and the attraction it selfe doe differ. So a Bone doth attract, yet not as it is a Bone, but as it doth participate of life and the function of the whole, yet it doth attract a proper iuyce as it is such a part and no other. But be it so, that attraction and other naturall functions doe belong and be ascribed to a Bone, a Gristle, a Membrane, and other such like parts as proper vnto them, in regard that they all doe properly and in their owne nature conueniently exercise them: Yet shall it follow that euerie part of the Bone and proportion of a Gristle or Ligament shall performe a proper Action? One and the same iuyce is common to all the Particles of the same Similar part. Wherefore this subdiuision of a particular Action in my opinion is not allowable.

But I conclude from that which hath beene said, that some parts doe performe a double office, namely, one common to all other parts, another proper which is committed to them and to no other parts; and yet tending to the vse of the whole. And this office or function is three-fold, to wit, Animall, Vitall, and Naturall: But what euerie one of these is, and how manifold, we haue before declared, and therefore they are here onely presupposed.

Some parts haue a double action, some onely one.

Moreover, some actions be manifest by themselves, yet their Organ is obscure & hidden, others be cleere and manifest both of themselves and in respect of their Organ, others be obscure both in themselves and in their Organ. I call that action manifest of it selfe which is sensible and may be iudged by the Sense; and that obscure of it selfe which doth not appeare but from those *workes* which proceed from it. I call also that manifest by the meanes of his Organ, whose Organ doth presently appeare, & in this without all doubt do all consent: but I account that obscure in regard of his Organ, when the action doth appeare, yet the Organ doth not presently bewray it selfe without much study, and discourse of the Mind, which is held of some onely for probable where about many doe dissent. Those which be manifest both in themselves & by their Organs be these; vociferation, pulsation, respiration, the locall motion of the parts, expulsion of Excrements, the expulsion of Vrine, the

what action is manifest of it selfe, and obscure of it selfe

the emission of the Seed, &c. In respect of both, with *Galen* in the 8 and 16 Chapters of his Booke *De Usu Partium*, are the apprehension of the Hand, the walking of the Feet, chewing, vision, hearing, &c.

Finally, these are esteemed obscure in respect of both; the transmission of the Blood, the carrying and recarrying of the Spirits, the generation of Animall Spirits, the production of Vitall, the sucking of Urine out of the Blood, Chylification, Sanguification, and the generation of Seed.

QUEST. V.

That Sense is not a pure Passion.

Whether the
object or the
organ doe
worke in the
Sense.

Their reason
which say
Sense doth
suffer.

That opinion
disproued.
1. Reason

2. Reason

Aristotle
thought the
contrarie.

Seeing therefore that vnto an action there doe necessarily concur an agent and a patient; the *agent* for to worke, and the *patient* to be a fit subiect for the *agent*, and to receiue the action: It may now be demanded whether the action proceed from the Organ vnto the sensible object, or from the object vnto the Organ, and whether this be to be accounted an *agent* the other a *patient*, or on the contrarie. Concerning this point there be diuers opinions of Authours, for some maintaine Sense to be passive, others active, others both active & passive. *Aristotle* doth contend for those which would haue sense to be passive, especially in the 118 Text of his second Booke *De Anima*, where in expresse termes he affirmeth, that to *perceiue* is a kind of suffering, and also calleth the object an *agent*: againe, in the 51 Text of the same Booke he saith, that Sensation hapneth in that which is moued and suffereth: And he seemes most exactly to demonstrate it in the 12 Text of his 7 Booke of Physicks, saying, *That the Senses are altered, for they suffer, and their action is a motion through a Body which suffers in the Sensation.* So that it may be gathered out of these places of *Aristotle* that Sense is made passively, that is, that the act of Sensation is not made by the Sense, but by the sensible object, & that the Sense doth nothing else but receiue the Species from the thing objected and suffer from it: But this opinion though it be approued of many and be held for *Aristotles*, yet it is neither agreeable to *Aristotle* nor to the truth. That the places cited out of *Aristotle* do not confirme this we will proue by and by, when as by many reasons we shall haue demonstrated how far distant it is from the truth. For first, If the Sense should only concur passively vnto Sensation, that is, if Sensation were only a reception of the sensible Species, then we must needs euen when we are asleepe heare, smell & see; seeing therefore that although when we are asleepe some certaine noyses or sounds be carryed to our Eares, & some odors do strike the Nose-thrills, and colors (if so be we sleepe with our Eyes open as some do) be presented to our Eyes, yet we do not heare, or smell, or see; it will follow necessarily that some thing else must concur vnto Sensation beside a simple reception of the sensible Species. Add further, that though we receiue a visible thing into our Eyes, and a sound into our Eares, yet we neither see nor heare when we are intent another way or haue our vnderstanding exercised in greater matters. Wherefore there must be some part of the mind present in Sensation; and hence it is that we sometimes seeke a small thing and yet see it not though we be verie neere it, and though it be already receiued into the Eye: Surely this is an argument most euident that the mind must be applyed to that thing which we would see, & that some thing more is required to Sense then the bare reception of the Species, for else a Glasse might also *perceiue* in as much as it doth receiue the Images. Moreover, if ouely the reception of Species were a Sensation, all action should proceed from the sensible Species, & that Species should be so prompt vnto action that it would worke euery where & vpon euery subiect, and so would make Sense; euen as heat doth make hot euery where & euery thing; but this is impossible, for who euer affirmed that Sense was made out of his proper Organ. Sensation is not therefore an action only of the sensible Species. Neither was it *Aristotles* opinion, for in the 37 Text of his 2 Booke *De Anima*, he teacheth the plain contrary, & affirmeth determinately, that the Soule is the efficient cause of Sensation, and therefore not the sensible thing; and in the 9 Chapter of the 9 Booke of his *Metaph.* he proues that vision is an action of the sight: and what can be more manifest then that which he expresseth in the 2 Chapter of his Booke *De Sensu & Sensili*, where he reprobeth *Democritus* for saying that vision was an operation of the object: and propounding the conformance of the similitude which the sensible thing hath with the Organ, he saith, *The sensible thing causeth the Sense to worke*, as if he should say, *The object doth excite and prouoke the Sense vnto action.* The point is as cleere as the Light; but yet what shall we answer to those contrarie places, quoted euen now out of *Aristotle*? For it seemeth in them to be plainly affirmed that Sense is passive. But I defer the reconciliation of this contradiction till the 7 Question, where you shall haue also *Cass. Plac.* his resolution.

QUEST.

QUEST. VI.

That Sense is not a simple Action.

THat Sensation is not a meere passion, is plaine from that which hath beene said. Now it is to be considered, whether it ought to be called an Action, that is, whether Sense doe *perceive* onely by doing or acting. And that setting aside all digressions, I may come to the matter; I say, Seeing euerie Agent in doing and acting doth also suffer againe, it followes necessarily, that the Sense doth continually suffer some-thing from the sensible Obiect: For there is no Man ignorant that to the effecting of Sensation it is necessarie that the Sense be conuerted into the nature of the sensible thing, but it cannot be conuerted but by alteration, because things of an vnlike nature cannot be made of one nature, except the one of them be changed, but the Sense & Obiect be of an vnlike condition. And this is it whereupon *Aristotle* so often beateth, that the Sense is *potentially that which the sensible thing is actually and really*, and except the Sense doe passe into the nature of the Organ, Sensation cannot be performed. Whence it followeth, that the sensible thing doth alter the Sense and turne it into it owne nature, and therefore *Aristotle* often times calles Sense an alteration, for so Sense is made. Now if the Sense be altered and changed by the Obiect, it is necessarie that it must suffer, because the sensible thing when it altereth the Sense worketh vpon it. Hence it is more then manifest that Sense is not perfected by a simple Action.

Passion is
necessarie to
Sense

The Sense
and the obiect
be vnlike

The Obiect
must alter the
Sense

QUEST. VII.

CASSERIUS PLACENTINVS his opinion.

IF therefore Sense be perfected neither by Action nor Passion, how shall we say that it is performed? I answer, that it is absolued and perfected, neither by Action only nor by Passion only, but by both together, that is, both by Action & Passion. That Action is requisite vnto Sense, is proued by the Negative part before refuted. We will add some Arguments wherewith we are purposed for the present to confirme the Affirmative. And first, If Sense should be made without acting, it would follow, that the Vegetative facultie should be more noble then the Sensatiue, because that to *doe* is more noble then to *suffer*, but no Man doubts that the faculties of the vegetatiue Soule are Actiue, wherefore least we should fall into an absurditie vnheard of and monstrous, we will grant that the Faculties of the Sensatiue Soule are also Actiue. Furthermore, if the Senses should not *work*, they were in vaine giuen vs by Nature, because the Organ onely would haue sufficed vs for Passion. Againe, if the Sense were onely Passiue, neither could the Sight see, nor the Hearing heare, nor the Smell performe his owne function, neither were any such like *predications* true of the other Senses, because these *predications* do intimate that the Sense doth produce out of it selfe an act of Sensation. Fourthly, Sensation is an operation of life, and therefore proceedeth from an internall and actiue originall of motion, for life is an *internall motion*, performed by that which liueth. Vnlesse therefore you grant that Sensation is an Action, it cannot be an operation of life. Lastly, Sensation is a second act, and the sensatiue Soule is a first act: for to *perceive* is an operation of the sensatiue Soule, and therefore *Aristotle* beside many other places, affirmeth in the seuenth Chapter, and the 127 Text of the second Booke *De Anima*, that to *perceive* is something more then the suffering of the Sense, whereby it is manifest that Sense is an Action.

Sense is absol-
ued by action
and passion
together

That action is
requisite.

and resolution of these difficulties, and the explication of a double truth, we must know that Sense is many wayes to be vnderstood.

First, as it is a reception of the Species, and so it is a Passion, for in that respect it suffers of the Obiect. And of this did *Aristotle* vnderstand that where he saith, *To perceiue is a kind of passion or suffering.*

Secondly, as it is a discerning and knowing of the Obiect by the Species receiued into the Sense, and so it is an Action, for so the Facultie doth worke vpon the Species, and so the Sight doth see, and the Hearing heare, and so of the rest; and so is *Aristotle* to be vnderstood, when he saith, that the Senses be Actiue.

Sense begins
in the Body
and ends in
the Soule

Thirdly and lastly, Sense is taken for both together; to wit, for an Action and Passion, when as the whole Sensation, that is, the perfect Act of Sense is vnderstood: For first, vnto the perfection of Sensation, there is need of Passion or an alteration of the Organ, from whence afterward follows the Action of the Facultie, which *Aristotle* did excellently note, where he saith, *That Sensation begins at the Instrument and Body, and is determined in the Soule:* as if he should say, the alteration of the Organ and the discerning of the Sensatiue Facultie doe accomplish a perfect Sensation. The same also must we vnderstand when he saith, that to *perceiue* is a second Act, and the Sensatiue Soule a first Act, because to *perceiue* is the operation of the Sensatiue Soule. Thus therefore may the difficulties propounded be easily resolued, and so *Aristotle* redeemed from contradiction.

QUEST. VIII.

How the Facultie is wrought in the Sense.

Question.

Sense is no alteration, but a knowledge of the alteration.

The Obiect cannot worke vpon the Facultie

The Facultie cannot change the Obiect

Solution.

The Organ is changed of it selfe, the Facultie as it is in the Organ

Seeing that (as *Galen* in the sixth Chapter of his second Booke *De Placitis* witnesseth) Sense is not an alteration, but a *discerning* or knowing of the alteration; because the Sensatiue facultie is not affected with the Obiect, but onely the Organ: It may therefore here worthily be doubted, how the Facultie can attaine to the knowledge of the Obiect, seeing it suffereth nothing from it, neither doth the Obiect *act* before the Facultie *perceiue*. For the Action of the Sensatiue facultie is a knowing and dijudication of the sensible thing: But it seemeth not to be possible, that the Sensatiue facultie can come to the knowledge of the Obiect, except that either the Facultie be some way affected by the Obiect, or the Obiect by the Facultie, but neither of these can be. For first, the Obiect cannot worke vpon the Facultie, because an incorporeall thing, is not affected by that which is corporeall. But the Facultie is incorporeall, and the Obiect corporeall. Beside, the Soule is not capable of Passion, and therefore neither are her Faculties capable. Neither can the Sensatiue facultie alter or change the Obiect. And this is plaine, as by many other reasons, so also because her sole and onely Action is Sensation. I say therefore, how comes it to the knowledge of his Obiect? And what is the efficient cause of the Dijudication or Iudgement, which the Facultie giues of the sensible Obiect, which we perceiue to arise from the motion of the Organ?

I answer, That the Sensatiue facultie doth suffer, and is changed by the Obiect, not by it selfe but by accident, to wit, as the Organ whose formall part and essence the facultie is, is changed by it. For seeing the Facultie is as it were the *idea* or *Forme* from whence the Action of the Organ doth proceed, when this corporeall Instrument is changed by the sensible Obiect, it remaineth that the Facultie it selfe (which together with his sensible Instrument doth grow vp into one Body, and so doth conspire vnto the same Action) is altered by accident and doth *perceiue* the alteration of his Organ. For all Organs of Sensation doe suffer by reason of their Body, but in respect of their Sensatiue facultie they performe an Act.

Passion doth affect the Facultie as it depends vpon the Organ; Action is the Dijudication or Iudgement, which is the office of the Sensatiue facultie, or of the whole Organ in respect of that Facultie where-with it is endowed: Not that the Facultie it selfe is altered or doth suffer, but because it *perceiveth* the alteration of the Organ.

QUEST.

QVEST. IX.

whether the knowledge of the Sensible thing be perfect in the Organ.

ALthough it be made manifest by that which hath beene said, that the proper action of the Sensatiue Facultie is the dijudication of the Sensible thing, yet there seemeth to be some difficultie behind: for, if the Facultie doe make this Iudgement of the object in the *Sensorium* or Organ, then those which sleepe with open Eyes should also see because the colour doth alter the Organ. In like manner a Sound might be heard, Odours smelt, and any Tactile qualitie might be felt by vs, seeing that the Organ is altered by the object, & yet when we are asleepe we neither doe see, nor heare, nor *perceiue* with any other Sense except the objects be very vehement. Haue therefore the Poets truly faigned that sleepe is the Brother of Death, because it doth deprive vs of all our Sense, yea of our verie Touch, inso much that it seemeth to extinguish the Creature and bereaue it not of Sense onely, but of Life also? Or else doe we *perceiue* while we sleepe, and know not that we haue Sense? The first cannot be, for although sleepe haue a great correspondency and affinitie with Death, yet it doth not deprive the Creature of Sense. For these things doe concur vnto Sense: A conuenient Object, an Organ fitly disposed, the alteration of the same Organ, and a Sensatiue Facultie, all which things we haue euen when we sleepe.

The Poets say
Sleepe is the
Brother of
Death.

Disproued.

What things
doe concur to
Sense.

First, The Object is present, for colour though we be asleepe, yet is it the object of Sight, and continueth to be actually an object as long as it is illuminated with the light of a Candle or with the day light; so also it is with Sounds, Odors and other objects of the Senses. The Organ is also present and so is the alteration of the same, seeing there is nothing which can hinder the operation of the Sensible Species vpon the Organ, or the alteration of the same. Neither is the Facultie wanting: for if the Facultie of one Sense should faile, all the Senses would be forfeited, and so of a living Creature should be made a Plant deprived of Sense and Motion.

Moreover, though we sleepe, yet our Organs liue and they liue by the Soule. If therefore the Soule with all her Powers and Faculties be wholly in the whole, and wholly in euerie part, it must needs be that if the Creature liue the Faculties of Sense must be present in euerie place where the Soule is. The Soule therefore is in the Organs of Sense, yea euen when we are asleepe, except you will say that the Soule dyes when we fall asleepe. Wherefore it necessarily followes that the Facultie of Sense is there also present in the Organ.

The Soule
with her Fa-
culties is who-
ly in the whole

Seeing therefore in sleepe we haue the object actually prepared vnto Sensation, seeing also the Organ fitly disposed is not wanting, and the iudging Facultie at hand, and that nothing more is required vnto perfect Sense, it is not to be doubted but that Sensation may be absolued in the Organ & Iudgment also giuen of the object euen when we are fast asleepe. But the reason why we doe not perceiue this Sensation, is, not because we haue no Sense at all, but because we know not that we haue Sense.

We haue sense
in sleepe but
know it not.

QVEST. X.

That by our outward Senses we doe not know that we haue Sense.

HAT we doe *perceiue* by the Organs of our Senses is euident enough by that which hath beene said, but it is doubtfull and vncertaine how we shall know that we haue Sense, seeing that this knowledge is not gathered from the externall Senses, for whatsoeuer is *perceiued* by them must be their proper object, but Sensation is the object of no externall Sense. Moreover, the externall Senses know nothing but externall things: but the acknowledgment of Sensation is no externall but an internall thing: wherefore it cannot be *perceiued* by the externall Senses. Thirdly, if together and with the same Sense we should *perceiue* and take knowledge of this perception, it would then necessarily follow, that the act of *perceiuing* and the object of Sense should be one and the same thing, which how absurd it is, I refer me to any Man to esteeme. Lastly, we doe not at the same time perceiue and iudge of that which we haue perceiued, but some-what after the act of Sensation we know that we did perceiue: a manifest argument that the one is a diuers act from the other,

and that with one Sense we doe perceiue, and with another know that we did perceiue. But this may especially hence be conuincd, that blind Men though they doe not see, yet they perceiue that they doe not see: seeing therefore the Organs of their Sight are vnfit for vision, it doth necessarily follow, that it is by another Sense that they perceiue themselves not to see. Now if it be by another Sense that we know that we doe not perceiue, surely it is another Sense also by which we know that we doe perceiue.

QUEST. XI.

Whence it is that we perceiue that we haue Sense.

We know not
that we per-
ceiue by Vn-
derstanding
nor Reason

IF therefore none of the externall Senses doe performe this Function, what may it be, is it the worke of our Vnderstanding or of our Reason? No: for this action is common to brute Beasts which be destitute of Reason, for they know when they doe not see, or heare, or smell, and so in the rest. And that they know so much may easily be gathered by the opening of their Eyes when they be shut, and pricking vp their Eares when they would see or heare. Neither need we wonder hereat, for they are enriched with some Functions that come neerer vnto Reason it selfe, as I might easily proue by many instances of diuers Creatures out of *Aristotle* and *Pliny* and other Historians if I thought it pertinent to this place. Seeing therefore vnreasonable Creatures do know when they *perceiue*, that is, haue vse of their Senses, it followeth necessarily, that that knowledge is not a worke of Reason.

It is no worke
of the Phan-
tasie.

we know that
we perceiue by
the Common
Sense.

Neither is it any worke of the Phantasie, in regard that it worketh after the act of *perceiuing* when the obiekt is not present; but the Phantasie ought to iudge (at least then when we haue vse of Sense) that we doe vse it, and after Sensation does nothing, whence *Aristotle* in the 136 Text of the third Booke *De Anima*, handling this point affirmeth, *That this knowledge of Sensation is wrought in the first Sense*. And this Sense is the common Sense, so called because it is proper to no one Sense, but is equally common to all; for Nature hath alwayes endeauoured to bring a multitude into an vnitie so much as possible may be: wherefore she hath ioyned in one common Sense all the outward Senses, whereinto as Lines going from the Circumference into the Center they may determine: and this hath the Philosopher verie elegantly declared in the 30 Text of his third Booke *De Anima*, and calleth this common Sense the *Medium or meane* between the externall Senses, considering them as the Circumference, and this as the Center. This is that Sense by which we know that we heare and see and performe the Functions of the other Senses: this is it which being bound in our sleepe maketh vs ignorant of our Sensation: this is it which except it be present all the other Senses are vnprofitable: this is it which offereth to the Phantasie the *Species* which the outward Senses haue *perceiued*, and the Phantasies to the Vnderstanding: in a word, this is it without which neither the externall nor internall Senses, nor the principall Faculties of the Soule could consist entire and absolute.

QUEST. XII.

Of the number of the Senses.

That there be
five Senses.

That there be
five proper
obieks of the
Senses.

The number
of the Senses.

IT is receiued of all Men that the Senses be five in number, but especially of *Aristotle* in the first Chapter and 128 Text of his first Booke *De Anima*, who saith, that beside Sight, Hearing, Smelling, Tasting, and Touching, there can be no other Sense assigned. And this is also confirmed by Reason, because there be onely five Obieks; Colours, Sounds, Odours, Sapours, and Tactile qualities: if therefore there can be found no other proper obiekt beside these five (I meane of externall Obieks) it doth necessarily follow that there is no other Sense beside these; so also because these five mentioned seuerall Obieks are so proper vnto their seuerall Senses, that none of them is iudged of but by his owne proper Sense: I say it followes hence that there are no fewer Senses then five, because the Obieks are full out five.

Furthermore, this number of five Senses is also confirmed by the number of the Elements, for *Aristotle* in the end of the second Chapter of his Booke *De Sensu & Sensili* saith, that euerie Organ is assigned to a particular Element, namely, the Eye to the Water, the Hearing to the Aire, the Smelling to the Fire, the Touching to the Earth, and Tasting, because of his neere affinitie to Touching is resembled vnto the same Element.

Neither

Neither doth that which may be objected any way infringe or impeach this opinion, to wit, because there is one onely Sensative Facultie, therefore that there should be but one Sense: For the reason why the Eye discerneth colors, the Eare iudgeth of sounds, the Nose perceiveth saavors, is not from the Facultie but from the temperature of the Organ; for the Foot also would see if it were endued with a temperament convenient for the discerning of colors. That the Organs have Sense, they have it from the Facultie; but that they perceive rather this then that object, they obtaine it not from the Facultie but from the temperament of their Organ. Wherefore, whereas the Eye doth discern of colors, the Eare of sounds, and the Nose of odors, it is not because there is a certaine Visive, an Auditorie and Odoratorie or Smelling Facultie, but because one and the same Facultie carrying it selfe in euerie Organ after the same manner, doth diuersly proceed into act, according to the diuers temper of the diuers Organs.

Objection.
Solution.

QUEST. XIII.

Of the order of the Senses.

Having thus determined the number of the Senses, it followeth in the next place that we speake something of the order of them, to wit, whether we ought to begin with the Sight as *Aristotle* and almost all Philosophers do, or with the Touch which is a contrarie way wherein Physitians and Anatomists do walke, and these be the two contrarie Sects concerning this matter of order, for none euer made doubt about the interruption or breaking off the order; but how many Authors so euer there be they haue either placed Sight in the first place, Hearing in the second, Smelling in the third, Tasting in the fourth, & Touching in the fifth: or else on the contrarie haue put Touching in the first ranke, Tasting in the second, Smelling in the third, Hearing in the fourth, and Seeing in the fift & last place.

As concerning the first, it is the opinion of the Philosophers and of *Aristotle* especially, who, both in the 2 Booke *De Anima*, and in the 2, 3 and 5 Chapters of his Booke *De Sensu & Sensibili*, doth ranke them in this order. Moreouer this assertion seemeth to be grounded vpon reason, because this is the order of the Elements which do concur for a *meane* or other help to the Senses; so that euerie Sense in respect of that Element vnto which it is appropriated, ought thus to be placed, and according thereto should their order and frame arise.

Senses to be placed according to the order of the Elements.

Sight is then the first of all the Senses, because Fire hath the first place among the Elements; for Sight is fiery, both in regard of the Sense, for it hath an ingenite or inbred Fire, as also by reason of the sensible thing, for except there be Light proceeding from a fiery Body, there would be no vision.

The Sight is fiery.

Hearing is the second because it is aery, for Aire occupieth the second place; and the Hearing is aery, both in respect of the Sense, because it hath an inbred Aire, and in respect of the object, because the Sound is formed in the Aire, so that it is of the Essence thereof.

Hearing is aerie.

Smelling is put in the third place, because as it is the middle betweene the other Senses, so it is appropriated to an Element (if I may so say) disposed in the middest of the rest. For that which is a *meane* betweene the nature of Water and Aire, as *Galen* doth well witnesse in the 2 Chapter of his Booke *De Odor. Instr.* falleth vnder the Sense of Smelling; because that which is neither so thin or rare as Aire, nor so crasse and thicke as Water may well be concluded vnder the name of a Vapor. Now that Smelling is vaporous both in respect of the Sense it selfe and of the thing sensible, we may haue occasion to proue hereafter.

Smelling is vaporous.

The Taft deserues the fourth place, because Water succeedeth Aire, and to Water this Sense is referred, as well because of the Communication, as also in regard of the Essence of the Object.

The Taft is watry.

The last place belongs to the Touch, because the Earth is in the last and lowest place, of whose nature and qualitie this Sense of Touching doth participate.

The Touch is earthy.

QUEST. XIII.

A conformation of the order of the Senses.

That the Senses ought to be thus marshalled among themselves and propounded in this order, the constitution and conformation of the Organs doe giue vs sufficient prooffe: for the proper Instrument of Sight is vayled with a very dense and thicke couer; that of the Hearing is more rare; that of the Smell yet thinner then them both,

The order of the Senses proued by the constitutions of the Organs

Parts.

And by the
tenuitie and
crassenesse of
the obiects.And by the
necessitie of
the Medium
or meane.

which *Galen* in the ninth Chapter of his eighth Booke *De Vsu Partium*, hath very well obserued, where speaking of this Sense, he saith, *If the couer were so framed, that it might be no hindrance to the Sense, then it ought to be so much more rare then that of Hearing, by how much the obiect hereof is of more crasse parts then that of the Eare.* The couer of the Tast is not onely more rare, but it is altogether spongy, as we haue shewed before in the Membrane of the Tongue. Lastly, the couer of the Touch is most rare of all.

This order is moreouer confirmed by the qualities of the obiects, for the obiect of the Sight is the thinnest and finest of all the rest, yea after a sort spirituall and not corporeall. That of the Hearing is more crasse, and the obiect of Smell yet more crasse and thicke then either of them: Whereupon *Galen* in the aboue-named place witnesseth, that the obiect of the Smell is of more grosse parts then that of Hearing: for saith he, *By how much the Aire is exceeded by the Light in the tenuitie of parts, by so much is a vapour surpassed by Aire.* The obiect of Tast is much more crasse then the former. But the Touch being earthy, must needs be the most crasse of all. Finally, this must needs be the order of the Senses, in respect of the Medium or meane; for the Sight aboue all hath need of a meane, but Hearing hath lesse need, and the Smell lesse then it. Tasting as some thinke without any meane at all, but especially the Touch as we haue partly proued already, and haply it will againe fall vnder our Discourse.

Lastly, the position of the Instruments are a confirmation of this order, for the Organ of Sight is placed without, but the Organ of the Eare is a little more inner, and the Instrument of Smelling more inward then them both, that of the Tast is yet more hidden, and the Instrument of Touching is called by *Aristotle* *τὸ ἐν τῷ ὄντι*, that is, *existing within*. By these Demonstrations therefore is this order of the Senses sufficiently confirmed, to wit, because euerie one ought to be placed in this assigned ranke. The Sight and Touch be the extremes because they are most distant one from another, by reason that the obiect of Touch is corporeall and materiall, and the obiect of the Sight incorporeall and spirituall; the Organ of Touch is placed within, but the Organ of Sight without; the Organ of Touch is couered with a most rare & thin vaile, that of the Sight with a most dense and thicke couer, because Sight vseth a Meane, but Touch none at all. Lastly, the Touch is earthy, & the Sight is fiery. The Hearing and Tasting are lesse distant one from another, and the Smell is equally distant from them all, and therefore by good right challengeth the middle place.

QUEST. XV.

The Arguments of the Philosophers.

Sight is by
Nature before
the other
Senses.And more
noble.

ALthough those things which are alleaged in the precedent chapters, seeme to proue nothing else but the ranke or following order of the Senses, and if any thing doe infer a conclusion, it is onely probably; yet there be which doe contend for the primacie of the Sight with strong Arguments. And first, they say that Sight is the first by Nature, as *Aristotle* witnesseth in the seuenth Text of his second Booke *De Gener. & Corrupt.* Wherefore if we will obserue the order of Nature, we must begin with the Sight.

Secondly, that which is more noble then the rest, doth deserue the first place. But Sight not onely in respect of the Sense, but of the Organ also, yea of the meane and obiect doth excell all the other in dignitie. To these we add, that Sight is more liable to our vnderstanding, and therefore we are to treat of it in the first place, because many things are found in it more facile and easie which also may prepare the mind vnto the knowledge of the other Senses: for the Organ thereof is very conspicuous, the meane is manifest, the obiect is clear, and other things which in the rest of the Senses be very obscure, are perspicuous & known in this: neither is it a sufficient obiection to say, that in respect of the act of *perceiving*, this Sense is most hard and difficult to be vnderstood.

QUEST. XVI.

The Arguments of the Physitians.

Why we must
begin with
those which
be most
common.

WE come now vnto the Reasons which are brought for the confirmation of this opinion out of *Galen* and the Anatomists, and they are taken partly out of *Aristotle* and partly out of the Propriete of Order. For *Aristotle* in the 37 Text of his first Booke of *Physickes* teacheth, that we must begin with those things which be most common; both because (as *Auerroes* expounds it) those things which be most common are best knowne, and also because otherwise we should too often fall into *Tautologies*, or vaine repetitions.

And

And *Aristotle* himselfe gives an excellent reason of this his owne Position, to wit, because without the knowledge of those things which are more common, the lesse common cannot be knowne.

Againe, who will deny that the Sense of Touching is more common then the rest of the Senses? Who knowes not that this Sense is common to all living Creatures? Yea it is so common in all, that without it no Sense can be performed, in so much that the same *Aristotle* confesseth, that euerie Sense is a kind of Touching. Beside, Art is but Ape or imitator of Nature, we therefore in the tradition of our Arts should follow the order of Nature, in which order we must begin with those things which are first (not in intention as the former Sect affirmeth) but in originall & generation: wherefore according to the order of Nature Touch seemeth to be put in the first place. To these we may add, that this Sense is more knowne then the rest, for a Man hath this Sense more exquisite then any of the rest; and it doth of necessitie follow, that of that Sense which we enioy most exquisitely, we should also haue most certaine knowledge.

Touch is the common Sense.

Touch according to the order of Nature is the first.

QUEST. XVII.

The Authors owne opinion.

THough these two Sects haue some shew of difference, yet in my opinion they may be reconciled, so that neither of both may seeme any whit blame-worthy, because they contend about a matter which is of no great moment, their strife being not about demonstratiue grounds. But because the Schoole of Physitians hath the more weightie Arguments, I will more willingly cast in my Lot with them. Yet may any Man draw a reconciliation betweene them from the diuers consideration of the order. Some follow the order of Nature in their Writings, which order may be vnderstood to be double, to wit, either the order of originall generation, or of intention, that is, either by what order Nature doth worke, or what end she presenteth to her selfe in her worke. According to the former consideration the end is the last, but according to the latter it is the first.

A diuers consideration of order.

Againe, some in their deliuerie of Arts follow that order whereby the Art is more easily taught, as for example, some things that come behind cannot be vnderstood vnlesse some other things be premised before. Others obserue the order of dignitie; so that by this diuersitie of order being conferred with that which we haue said before, it may easily be gathered what we ought to conclude of either Sect.

QUEST. XVIII.

Whether the Senses doe need a Medium or Meane.

IT seemeth to be no hard Question to determine whether the Senses need a Medium or meane, because out of *Aristotles* Philosophy we haue as it were an Oracle, 1000 times repeated that *The object placed vpon the Sense doth make no Sensation*, especially seeing hitherto it is receiued for such an vniuersall principle and ground, that he which denyes it deserues not to be confuted. But weighing this as all other Theoremes in the equall Ballance of Reason, I am bold to demand whether this Position deserue the title of a Principle? As for *Aristotle* he acknowledgeth it indeed for a principle, and in many places resolueth vpon it for an infallible & vndoubted Axiome without adding any reason thereto: but whether herein he hath well done, and whether it be such a ground and principle or no, it will appeare by the due consideration of the conditions required in a principle.

An Axiome questioned.

The first condition therefore of a Principle is (as it appeareth *Ex Posterioribus Analyticis*) that it may be truly affirmed of euerie particular of the same kind, and in my iudgement saith *Casseri Placentinus*, this Axiome transgresseth this condition, because it agrees not to euerie Sense to haue a Medium, for that Tasting and Touching are absolved without.

Touching and Tasting without a medium.

But some may haply doubt how these two Senses can be performed immediatly, and yet a Medium be required to the rest. The answer is at hand, because the Organs of some Senses are so sensible that they would easily be offended with the contaction of their objects. So the Sight will not admit of the Touch of any thing, and a vehement motion whereby the Sound is generated would offend the Organ of Hearing if it should come immediatly vnto it.

The reason why the other are not.

Againe, A fumid exhalation which falleth in with the Sense of Smelling would hinder Respiration, and except it were transported through a Medium or meane, it would be offensive and hurtfull to the Organ.

Some Senses
perceive mate-
rially, others
spiritually, as
Sight.

Not the color,
but the thing
colored of-
fends the Eye.

The Taste and
Touch receive
reall qualities.

The Sight
doth especially
need a medium

The Hearing
less.

The Smelling
yet less.

Tasting and
Touching
none.

Lastly, some Senses doe *perceive* their objects not materially but spiritually; and then the *Species* must be drawne from the object through a *Medium*. Some receive them materially, and those never need a *Medium*. For a colour cannot really attain to the Organ, because an accident out of his subiect is nothing: Whereupon it followeth that not the colour placed about the Eye doth offend it, but the *coloured* or subiect of the colour. But put case that colour could really without any damage be imposed vpon the Eye, yet it would not moue the Sense, because it would condense and thicken the Eye: for by this immediate contacti- on the colour doth worke vpon the *Diaphanum* or that which is translucent.

The Touch and the Taste haue therefore no need of a *Medium*, because they doe not receive intentionall or abstracted *Species*, but reall qualities; for if they should receive spiri- tuall formes, then they must discern of them a farre off without the contacti- on of the ob- iect; for the *Species* are diffused into an ample distance; but the Taste and the Touch are not perfected without contacti- on.

We see moreouer in these Senses reall affects of the objects, which could not be vnlesse they should be *perceived* really: But these things shall be more at large discussed in their proper places.

For a plainer dilucidation of the truth, we must obserue that all Senses haue not alike need of a *Medium*; but there is a certaine order and degree of this necessitie. For the Sight doth especially need a *Medium*, because it is most of all spirituall, and there is no Sensation at all of a reall colour immediately placed vpon the Eye.

A *Meane* is also requisite to the Hearing, yet it hath lesse need thereof then the Sight, for a Sound imposed vpon the Hearing maketh a kind of Sensation, but very imperfect, name- ly, such an one as is offensive to the Organ.

The Smell in like manner hath vse of a *Medium*, especially if the smoaky exhalation be vehement; for then it hinders Respiration and hurts the Organ: yet an Odor may be *per- ceived* without a *Meane*. Whereupon when we would *smell* any thing perfectly, we hold our Noses close to it: so that the *Smell* seemeth to be in the middle betwixt those *Senses* which need a *Meane*, and those which are performed without it.

Taste also though it be made by contacti- on, yet requireth necessarily an humiditie, which may bring the Savors out of *power* into *act*. But Touching hath need of nothing saue the contiguitie of the Tactile body, being performed without the helpe of any other *Meane*. And thus I thinke it is plaine what we may determine of this Question.

QUEST. XIX.

What the Medium ought to be, and of what kind.

After we know which of the Senses doe need a *Medium*, it followeth that we make inquirie to find out what this *Medium* is, and how it ought to be affected. And herein we must first obserue that the *Medium* ought alwayes to be present, least when all things else requisite for Sense be fitly disposed, yet for fault of a *Medium* we be made lesse able to performe this act of Sensation. Wherefore the *Medium* by whose inter- position we *perceive* is not Fire, for this is not alwaies at hand but Aire, for this doth alwaies encompasse vs about, it is alwayes present, in it we lead our liues.

Secondly, this *Medium* should alwayes consist in a middle place betwixt the Organ and the object; for hence it hath the name of a *Medium*, yet so, that it touch both the Organ and the object, for otherwise it can not performe his office. But there is no Element which is continually contiguous with our Organs but the Aire.

Thirdly, it is necessarie that this *Medium* be void of all sensible qualities, for otherwise it would bring the object adulterated or defiled to the Organ, and affect the Sense with a proper qualitie of his owne. Wherefore no compounded body is fit for this function, be- cause all compounded things are sensible of themselves.

If you object that there be no Elements exquisitely pure, and that therefore none of them can be a fit *Medium* being themselves sensible. I grant indeed that no Element that is neere vs is perfectly pure, yet that Aire that is neere vs wherein we liue doth exceed the rest in puritie, and is cleere from all qualities except Tactile, so that it may be accounted for a *Medium* to all the rest of the Senses except the Touch.

And is there then one *Medium* seruing to all the Senses? Yea, for this is the conclusion which is inferred from the former premises, to wit, because this alone is most pure, and is alwaies present with vs, this alone is continually in the middest betweene the Organ and the object,

Fire is not
the medium,
but Aire.

2 Reason
why the Aire
is the medium.

The condition
of a medium
agreeth with
no Element
except Aire.

object, this is alwayes close adioyning and touching both the Organ and the object. The Aire therefore alone serueth for a *Medium* to the Sight as it is Tralucēt; to the Hearing as it is fit to transport Sounds; to the Smell as it is capable of Odors.

But it may be objected, that if the Aire be the onely *Meane* of the Senses, then would it follow, that Fishes which liue in the Water haue no Sense.

I answer, that for their Sight the Water serueth for a *Medium*, but other Senses they haue none (saith *Placentinus*) sauing their Tast & Touch, and these two haue no need of a *Medium*, or if they haue other Senses, yet are they but imperfect. But if any Man will yet more instantly vrge, that they haue the Sense of Hearing. We grant they may heare, but most imperfectly, and for such imperfect Sensation the Water serues in steed of a *Medium*. But we speake here of perfect Sensation, whereas the Sensation of Fishes is not simply perfect, but onely in their owne kind, to wit, so farre forth as they haue need of it.

Lastly, this condition of the *Medium* is required to the perfect performance of Sense, namely, that it be not too spacious or ample, and also that it be not too narrow or scant. But what is the limit or extēt of this *Medium*, that is, how farre it ought to extend it selfe, is impossible to be determined, for this limit or extēt must almost infinitely be varied, according to the magnitude, paruitie, and vehemencie, as also according to the vigour and strength, or imbecilitie and weaknesse of the Sense: For we doe not discern Mountains, Cities and whole Countreys but a farre off, and lesser things we doe not see except they be neere at hand. So we doe not perfectly and without offence to the Organ heare a vehement Sound, except there be a great distance betwixt the Sense and the object; nor a low voyce, except we be neere vnto it. And the same reason is of the rest.

The termination of the medium is diuers.

QVEST. XX.

What an Object is.

AN Object or that which is sensible, is a quality which moueth the Organ, and is iudged of by the Sensatiue Facultie. And although that which is Sensible be two-fold, proper or common, yet I conceiue this definition to be peculiar to the proper object; vnlesse haply it may agree to some of the common, and therefore we will seuerally define them both. Proper Objects therefore, as *Aristotle* witnesseth in the 63 Text of his second Booke *De Anima*, are those which cannot be perceiued with any other Sense, and about which the Senses in discerning are not deceiued. And this definition (of it selfe) agreeth to the thing defined. For in that sometimes the Senses erre about their proper Objects, it hapneth not of themselues, but from some accident, to wit, from the deprauation of such things as doe concur to this Sensation; as for example, when all things appeare yellow to those that are sicke of the Iaundies, that hapneth because the Eye is tainted with the yellow colour of choller; and when Aguish Men do iudge sweet things to be bitter, it comes also from choller where with the Tongue is affected, and that is from euent and accident, not from the proper condition of the Sense. Wherefore seeing that when such impediments or lets are remoued, and the Object, *Medium* and Organ are naturally disposed, the Sense cannot be deceiued about his proper Object, it is by good right thus absolutely defined.

An Object is two fold.

What a proper Object is.

The Sense is not deceiued about his Object.

How many proper objects there be.

For the number of these Objects, they are as many as are the Senses, for Colour is the Object of Sight, Sound of Hearing, Odors of Smelling, Savors of Tasting, and Tactile qualities of Touching.

Common Objects are those, which are perceiued, not of all the Senses as some would haue them, but of more Senses then one. Which *Aristotle* teacheth very well in his Booke *De Sensu & Sensili*, where he affirmeth, that they are therefore called common Objects, because they are common though not to all the Senses, yet at least to the Sight and Touching, for by these two are all things perceiued, though not after the same manner as their proper Objects, to wit, by sending a Species from them, or by attaining really to the Organ; but as it were, after certaine manners and conditions ioyned with the proper Objects in order vnto the motion of the Senses: so that they doe not absolutely and primarily moue and affect the Sense, but onely together with their proper Objects. And because the second do not worke without the first, therefore the common Objects are not perceiued by the externall Sense without the proper. And these common Objects are five in number according to *Aristotle*, Motion, Rest, Figure, Magnitude, and Number.

What a common object is.

When the common objects moue the Sense.

QUEST. XXI.

Of the Organs of the Senses.

What an
Organ is.

THe Organ or Instrument of the Senses (as *Aristotle* witnesseth in the 122 Text of his second Booke *De Anima*) is that wherein the power and force of perceiuing is seated. And this Instrument is the Eye in the Sight, in the Hearing the Eare, in the Smelling the Nose-thrills, in the Tast the Tongue, and for the Touch, though all the Skin, yet especially that of the Hand. But yet the vertue or facultie of Sensation doth not reside in the whole Organ, but in some certaine Similar Particle, of which kind is the Christaline humor in the Eye, the Nerue of Hearing dilated in the Eare, the Mamillarie Proccesses in the Smell, the proper Flesh or Pulpe of the Tongue in the Tast, and in the Touch the true Skin; the other parts of the Organs assist this Particle, keeping it as it were in tune, or preserving the harmony thereof from the offence and incurfion of outward iniuries; for otherwise this sweet Musicke, content and proportion, would by the ouer-vehement force and change wrought by excessiue objects be destroyed, which concordance being broken there can be no Sensation.

And thus much shall suffice to be spoken of the Senses in generall; we will entreat more at large of the particular Senses in their proper places, where also we will note some things concerning their Organs which will be worthy your obseruation. And first of the Sight according to the order we before obserued in our Anatomieall Historie.

QUEST. XXII.

Whether Sight be made by Emission or Reception, where the nature of the Sight is accurately explained.

Our particular Controversies concerning the Sight shall begin with that notable Question concerning the nature and manner of Vision or Sight, which is indeed rather Philosophicall then belonging to the Art of Anatomy; notwithstanding because *Galen* hath elegantly ventilated it in his Bookes *De Vsu Partium* and *De Placitis Hipp. & Plat.* it shall not be altogether impertinent to insert some collections in this place which yet we must fetch out of the secret mysteries of Philosophy.

There are three especiall or most notable opinions of the Philosophers concerning the manner of Sight. Some thinke it is made onely by Emission of some thing out of the Eye. Others onely by Intromission or Reception of some thing into the Eye. And the third sort contend, that it is made partly by Emission, partly by Reception or Intromission.

Of the first Sect there be diuers Authors, but all of them disagreeing among themselves. The Masters of the *Optickes* thinke that certaine beames doe issue from the Eyes and reach vnto that which is to be seene: the figure of which beames they conceiue to be Pyramidal, the Cone or Point whereof is in the Eyes, the Basis in the thing to be seene. *Pythagoras* thought that Sight was made by an Emission of Light out of the Eye vnto the Object, which Light is reflected againe vnto the Eye, euen as a Hand-Ball stricken against a Wall doth rebound backe from the Wall vnto the Hand with an equall force.

Empedocles, *Hippocrates*, and *Nicemus* thinke that Sight is made not by Emission of Light onely, but of beames also. *Plato* thinke that the Eye sendeth not any beames forth of it, but onely Light, and that it also reacheth not vnto the thing seene, but vnto a certaine or proportionable space of the Medium. *Democritus*, *Lucippus*, and the *Athenian Epicurus* conceiued that certaine Images or Formes did flow from all things through the Motes which be in the Aire. *Chrysippus*, and the whole Schoole of the *Stoickes*, thought that a certaine Spirit ascended from the Heart vnto the Apple of the Eye, which Spirit was extended as farre as the Object. And these are the different conceits of the Authors of the first opinion, whereby it is supposed that some thing is sent out of the Eye vnto the visible Object, which opinion the *Platonists* confirme by these Reasons.

First, they say that Witches doe fascinate or bewitch onely by beholding one with their Eyes: Whence it is that the Poet saith:

Nescio quis teneros Oculis mihi fascinat Agnos;

I wot not well what witching Eye,
My tender Lambes hath done to dye.

Secondly,

Three different opinions concerning the nature of Sight.

The first opinion of Emission.

The Masters of the opticke Art.

Pythagoras.

Empedocles.

Democritus.

Chrysippus.

The *Platonists* Arguments.

Secondly, they say that a Basiliske doth infect a Man, onely by seeing him.

Thirdly, that a Menstruous Woman doth infect a Looking-Glasse as it were with some materiall corruption.

Fourthly, that if a Wolfe behold a Man he will become hoarse.

Fifthly, that *Tiberius Caesar* is reported to haue astonished a Souldier, onely by casting his Eye vpon him.

Sixthly, that *Antipho* (as *Aristotle* reports in the third Booke of his *Meteors*) had his own Image euermore before his Eyes.

Seuenthly, if we did not see by emission how it comes to passe, that when we would see more exactly we draw the Apple of our Eye into as narrow a roome as we can, Is it not to this end that the beames and spirits going out of our Eyes may be more vnited?

Eighthly, if nothing were sent forth of the Eye, how could the Eye be so wearie with continuall looking?

Ninthly, if Vision were made by reception & not by emission, we needed not to conuert our Eye directly to the visible object, for we should see whether we beheld the thing or no.

Tenthly, we could not see the magnitude or figure of many things, for the Eye being so little a body cannot receiue such great objects into it selfe.

Eleuenthly, if it were by reception, then would it follow that the more we dilated the Apple of our Eye, the better we should see, because our reception would be large.

Twelfthly, diuers or contrarie Species or formes would together and at the same time be receiued into the same Eye, because at once it doth behold two contrarie objects, as blacke and white.

Lastly, the least thing should be as easily perceiued as the greatest, the contrarie whereof is manifest, for the sharpe Point of a Needle held vward to the Sky is not perceiued, because the beames being separated cannot meet in one, by reason of the paruitie of the object, but if we would see it, we must of necessitie with-draw our selues to the one side.

To conclude, the Eyes are of a fierie nature, for they are both pyramidall & continually mouable and neuer stiffe, but it is the propertie of Fire alwaies to send some thing from it, as light, beames or heat. These be the principall reasons of the *Platonists*, and of the Masters of the *Optickes*.

Let vs now lend our Eares vnto the Fautours of the other Sect, the Prince of which Company and opinion is *Aristotle* in his second Booke *De Anima*, and in his Booke *De Sensu & Sensili*, and his steps haue all the *Peripatetickes* followed, as *Alexander*, *Themistius*, *Auerroes*, and the rest: and these thinke that *Sight* is made onely by reception of some thing into the Eye, and not by emission of any thing forth: and that for these Reasons.

The opinion of the *Peripatetickes* that Sight is by reception onely.

First of all, because that Sense being a Passion it ought onely to be made by reception. So Hearing is made onely by the reception of Sounds. The Smell by reception of Odors. The Taste of Savors, and the Touch of Tactile qualities.

Their Arguments

Moreouer, they that haue more moist and humid Eyes doe alwaies conceiue the objects to be greater then they are, because the Species are represented in a greater shape by reason of the humiditie.

Thirdly, an ouer-vehement object doth hurt the Sense.

Fourthly, we see in a Looking-Glasse the Image of the thing opposite vnto it, which we could not doe vnlesse the Image of the thing were caryed from the object vnto the medium and so vnto the Glasse.

Againe, *Aristotle* in the third Section of his *Problemes* asks the Question, why the right Eye should with more agility performe his function then the left, and yet the Eares do both of them heare alike? He answers, that Faculties are actuated by doing, but the Senses and their Organs doe equally suffer.

Sixthly, old men discern better of such objects as be a farre off then of those which be neere, and that not because of the light, or the beames, or spirit sent forth of their Eyes, for they are very small, impure and darkish; but because the Species or forme coming from a remote object is made more slender & spiritual, and more apt to be receiued into the organi.

Seuenthly, the smallest Starres in the cleere Winter may be discerned, and not in Summer, because their Species or formes being receiued into a crasse and thicke Aire are there terminated and multiplycated: but in Summer by reason of the raritie and thinnesse of the Aire they cannot be receiued terminatiuely or definitely (for of necessitie we must vse our Schoole termes to expresse these matters of Art) neither yet be sufficiently multiplied that they should attaine vnto our sight.

Galen

Galen's
opinion.
Our opinion
that Sight is
made by
reception:

Galen in the seventh chapter *De Placitis*, and in the tenth *De Vsu Partium*, to the end that he might reconcile the *Platonists* with the *Peripateticks*, determineth that Sight is made partly by Emission, partly by Reception. Truly for my owne part I reuerence *Galen* as a Master, and he stands in no need of my patronage or approbation, he is sufficient of himselfe, yet as he was often wont to say, *Vincat utilitas*, Let profit preuaile; so we say also, *Vincat veritas*, Let Truth preuaile. I had rather therefore thinke with *Aristotle* (whom I esteeme & respect as another Nature, but an Eloquent Nature) that Vision is onely made by Reception of Species, and that nothing is sent forth of the Eye vnto the thing seene which may helpe the Sight, that is, neither Beames, nor Light, nor Spirit. The truth of this opinion may be strengthened with these Reasons.

The first
Reason.
That the Or-
gan of Sight is
watry & why

First, the Organ of Sight is watry; now it is the propertie of Water to receiue: that it is watry may be thus demonstrated. The Organ of Sight ought to be Tralucēt that there may be a kind of Analogy or proportion betweene the Obiect, the Meane and Organ, that is, betwixt the Agent and Patient. But of shining and cleere Bodyes, some are rare & thin, others more dense or thicke. The rare Bodyes doe easily receiue the Species or Images, but they do not retaine and hold them; so the Aire is full of Species, but they presently vanish away & are not perceiued by reason of the raritie thereof: nay and I say, that such Species cannot be discerned in a Glasse except they be retained by Lead, or some such like dense and thicke Body. That therefore these formes of visiblie things may be held and retayned in the Eye, there is required both a translucent and thicke Body, and of this kind is Water; for Fire and Aire be cleere indeed but rare. The Organ therefore of Sight is watry, of which nature also are the principall parts of the Eye.

The 2 Reason
which is
Alexanders.

There is a verie elegant Argument of *Alexanders*, which is on this manner. That which is sent forth of the Eye is either corporeall or incorporeall. But it is not incorporeall, because incorporeall things can neither issue forth of the Eye, nor change their place, nor be in the Eye as in a place. It is not corporeall, because then the Eye in one day would vterly be destroyed, neither could it in a moment be carried as farre as the Sky, because no corporeall substance is moued in an instance.

To these we add, that when the Wind doth blow it would be dissipated, and so there would be a Penetration of Bodyes which is against Nature. Now if you should thinke that the Aire would giue place to the corporeall substance going out of the Eye, there could be no Sight at all, because there would be no continuation of those Beames with the Eye but some Body would interpose it selfe betwixt them.

The Solution
of the *Plato-*
nists Reasons.

As for those Arguments which the Masters of the *Optickes* and *Platonists* oppose against this Truth, we will thus in order answer, repell and refell them.

First, we deny that Fascination or Bewitching is done onely by Sight, except it be by Magicke Art.

For the second and third, we also deny that a Basiliske or Menstruous Woman doe by their lookes infect any thing, but it is by reason of a certaine corrupt and poysoned vapour which breatheth out of their Mouth, Eyes, Nose-thrills, and from their whole Body, which by continuation and succession doth infect the Aire.

Fourthly, that which they obiect concerning Wolues, is more worthy of derision then of confutation.

As for *Tiberius*, he did not astonish his Souldiers by any Beames proceeding from his Eyes, but by his horrid and fearefull looke and countenance.

Sixthly, for *Antiphon* it is well knowne he was a Foole, and therefore the fault of the oc-cursion of his Image or resemblance alwaies before him was in his Braine not in his Eyes.

Seuenthly, we doe angustate or straighten the Apple of our Eyes, least by the externall Light our internall Spirits should be dissipated.

Eighthly, the Eye is wearied with looking, by reason of that force and endeaour which the Facultrie vseth to administer for the establishment or fixing of the Eye.

Ninthly, the Eye must be conuerted or turned toward the visiblie obiect, because there can be no Vision but by a right Line.

Tenthly, the magnitude of a thing is not receiued into the Eye, but onely the Species or Forme of it, which because it is a thing immateriall, may be wholly receiued into the Eye.

To the eleuenth, we say, that the dilatation of the Apple of the Eye doth exolue or spend the Spirits which are of absolute necessitie for the reception of the Species.

To the twelfth thus, both white and blacke colours may at one and the same time be re-
ceiued

ceived into the Eye, because they are received onely by an intentionall and incorporeall Species or Forme.

Lastly, the Point of a Needle is therefore not perceived, because it is not a proportioned object to the Organ. By these it is plaine and manifest, even to the dullest apprehension, that Vision is performed not by emission or sending forth any thing from the Eye, but only by reception of the Species into it.

But the nature of this reception is most obscure and folded vp in many secret difficulties, for the enodation whereof, that this secret may appeare evident, foure things are to be discussed of vs. First, what it is that is received. Secondly, where or into what part of the Eye this reception is made. Thirdly, when it is made. Fourthly, how it is made.

As concerning the first Question, *Democritus* and *Lucippus* thinke that corporeall objects are received. *Epicurus* suppoeth onely the Beames of the visible object are received. *Alexander* that the Image onely of the thing is received, not as it were in a Subject, but like as in a Glasse. We agreeing with *Aristotle*, thinke that onely the Species or Images are received, and that the qualitie of these Species is incorporeall, immateriall, indiuiduall, the Philosophers call it *intentionall*, which is produced in the *medium* or *meane* and Organ, and so multiplied by a simple effluence or emanation as Light proceedeth from the Sunne, and a Shadow from a Body. This Species, I say, is not it selfe scene, but it is that whereby we see, for onely the object is scene.

The Eye therefore may very well be compared to a Looking-glasse receiuing into it the Images of such things as are objected and set before it. For a Glasse doth receive all the Species, not sending any thing forth: yet in this doth the Eye differ from a Glasse, that there is no vertue of the Soule in a Glasse which can refer and transmit the Image received vnto any other thing as it were vnto a Iudge.

But some will haply demand here, if the Species or Image received be immateriall, how can it affect the Sight by seuering or gathering together of the Spirits?

I answer, that the Eye is not affected by the Species, but by the colour, according as it is more or lesse splendent or enlightned, for all enlightned things doe dissipate, by reason that our airy and splendent Spirits doe vanish into that light which is like vnto them: So white things, because they haue much light doe dissipate the Spirits, but blacke doe gather them because they are contrarie to the Spirits. So when night comes, the heat is recalled from without inward, and as *Galen* teacheth in his Commentarie vpon the fifteenth Aphorisme of the first Section, we sleepe longer in Winter because the Nights are then the longest.

Wherefore lucide and white objects doe hurt the Sight, yea sometimes they make a Man blind, because the visive Spirits being drawne out, and as it were intified by that which is like vnto them, doe breake forth of the Eye with so great a violence and force, that by such irruption, either the substance of the cristalline humor, or the coat thereof, or something else in the Eye (which hath many tender parts) is either broken, or at least suffers some notable alteration.

It will be againe objected, if the reception of the Species be immateriall, why should the Eye be wearied with continuall seeing? Why doe not Prominent and Goggle-Eyes see better then other, because they are more apt for reception?

I answer, that the Eye is wearied, not by the impression of Species, but by the force and endeavour which the Facultie vseth to doe his worke, which is especially to firme the Eye, or hold it stedfast and to containe the Spirits; but those that are Goggle-eyed haue not so good Sight, because their Animall Spirits are dissipated, which are especially necessarie vnto the Sense of Seeing, that being ioyned with externall Light they might transmit the Species vnto the interiour Sense.

The second Proposition was concerning the place of this reception, to wit, into what part of the Eye the Species be received. And here it will not be in vaine to examine the different opinions of Physitians and Philosophers. Some thinke that they are received into the substance of the Braine, grounding vpon the doctrine of *Galen*, who teacheth that all Sense is from the Braine. *Aristotle* saith, they are received into the *Pupilla* or Apple of the Eye, vnderstanding by the Apple the cristalline humor. *Galen* saith, some time into the cristalline, some time into the Cobweb-coat, which he saith, is smother and more polished then any Looking-Glasse. *Auicenna* sayes, they are received in the meeting of the Opticke Nerues, and thence it is (saith he) that the object appeareth single, because the visible formes are vnited in that coition or coniunction of the Optickes. We determine that they are received

Four things to be observed in this reception.

what it is that is received.

That onely the Species are received.

The Eye is like a looking glasse.

Of the place of this reception.

Aristotle

Galen.

Auicenna

ceiued into the Cristalline, because it is the principall and primarie Organ of Sight, placed in the verie Center of the Eye, and differing from all the other parts in substance, figure, and qualities. But if you would reconcile all these, then say, that the *reception* is made in the Cristalline, the *refraction* in the Coats, the *perfection* in the coition or meeting of the Optickes, the *perception* and iudging in the Braine.

Of the time
of reception.

Concerning the time of this reception, which was the third Question, all do agree in one, that vision is made together with the perception of the Species, but this perception is made in an instant, for the Heauen is seene all at once, because the Light which produceth or bringeth forth these *visible Species*, doth diffuse it selfe, and transporting them together through the Aire, placeth them in the extreme Superficies thereof, that is, next of all to the Eye-lid, so that when the Lid opens, presently the Species is offered to the *Pupilla* or Apple, and in a moment of time is ioyned there-with.

Of the manner
of reception.

Lastly, the manner of Vision is thus, it is made by the reception of sensible Species, not of Bodyes, which Species, although they seeme to haue some tast of the condition of their owne matter, notwithstanding they are not carryed materially and as Bodyes are carryed, but like the Shapes or Images of Bodyes, brought from the aspectible object vnto the *Pupilla* through the Aire (as a *meane*) by right Lines vnto an acute Angle. He that desires to heare more of the manner of Vision, let him read *Alexander* and *Simon Simonius*, a Man both for Physicke and Philosophy very excellent, commenting vpon *Aristotle* his Booke *De Sensu & Sensibili*.

QUEST. XXIII.

Whether any thing within the Eye may be seene, and whether it may be seene by it owne proper forme, or by another, where also are explayned some things concerning the nature of Suffusion and of Visions or Apparitions.

Whether any
thing within
the Eye may
be seene.

Having resolved that Ancient Question concerning the manner of Vision, we will proceed to the resolution of two other doubts, that so there may be nothing wanting that can be desired to the perfect nature of this Sense of Sight. The first therefore is, whether any thing which is within the Eye may be seene. Then whether that which is seene, is seene by his proper Species or by another.

The first
Reason.

That nothing within the Eye is visible may be thus demonstrated, *Aristotle* in his second Booke *De Anima* writeth, *Sensibile positum supra sensorium sensationem non facere. A sensible object placed above the Sensorium or Organ doth not performe any Sensation.*

Secondly, if any thing should be seene within the Eye, then would it follow that the object and the Instrument receiuing the object should be the same.

Thirdly, the Philosopher teacheth, that there be three things requisite and necessary vnto the Sense of Sight, the *Object*, the *Medium* or *Meane*, and the *Instrument*.

Lastly, Vision is made by the reception of such Species as are produced and multiplied in the Aire; but if any thing within the Eye should be seene, the Sight would not be made by the Species, but by a reall Object.

To these we will add, that it would also follow that the Grapy Membrane which is diuersly coloured would be seene, but that is not seene: wherefore we conclude, that nothing within the Eye can be seene.

That some-
thing within
the Eye may
be seene.
Authoritic.

Now on the contrarie, that something within the Eye may be seene, is proued by Authoritie and Experience. First, the Authoritie of *Aristotle* in the second Chapter of his Booke *De Sensu & Sensibili*, and in the fourth of his *Meteors*, seemeth thus to perswade vs, for (saith he) when the Eye is rowled or moued in the darke, something may be seene within the Eye. This Authoritie is also backed and confirmed by Experience, for in Visions or Phantasmes which doe vsually goe before Suffusions, there doe appeare certaine figures, magnitudes, positions, and diuers colours, all which are resident in the Eye, and not in the Aire, for then they would be equally perceiued of all Men; and when a Criticall euacuation of Blood by the Nose is ready to follow, there are seene afore the Eyes certaine red shadowes which they call *Marmoryga*. But that these things may appeare more plaine and euident, it will be behoofefull to note a few things concerning the nature of Visions or Phantasmes.

Two kinds of
Visions.

Concerning such Visions, some are (according to *Galen* in his fourth Booke *De Locis Affectis*) of Idle-headed Men, by reason of the wandring and vncertaine motion of the

Images;

Images; and so Franticke Men doe hunt after Flyes, catch at a Flocke or Feather, pickle at Strawes, and are terrified, yea start and flye from vaine and false Images. These Visions are not Diseases of the Eye, but they are Symptomes of the Braine and of the Imagination.

Visions by the fault of the Braine.

There are also other Visions and representations which are proper to the Eyes and the externall Sensitive Facultie; when false Phantasmes doe obtrude and offer themselves to the Eye: For as *Anicen* writeth, there may appeare some small Bodyes in the Aire, and diuers mingled colours which indeed are nothing. This Vision is tearmed by the *Arabians* Imagination. But *Galen* defines it to be an externall apparition hapning by reason of a darke or cloudy vapor which is betwixt the cristaline and the horny Coat. It is most what a Symptome or signe of a depraued Sight, because certaine outward colored things do appeare which indeed are not; the Eye iudging that to be without which indeed is within it.

Visions proper to the Eyes.

What a Vision is.

The cause of this Symptome is acknowledged of all to be that shadow or cloudy and darke vapour which doth interpose it selfe between the horny Coat and the cristaline humor. I called it darke or shadowy, that is, Imperuious (as the *Barbarians* say) they meane not bright or translucent. For if that Body which is betweene the horny Coat and the cristaline were translucent, these Visions would not run before the Sight, but the *Species* of visible things that are pure and not mixed, would haue been carried to the cristaline.

The cause of such apparitions.

The place of this small Body or vapour is the whole space from the horny Membrane vnto the cristaline: For if this vapour had been contained betwixt the cristaline and the coition or meeting of the Opticke Nerues, it would not haue raised any such representation in regard that the whole reception of the *Species* is made in the cristaline alone. But if peradventure this vapor be mingled with the glassie humor which doth hinder the arriuall of the internall Light, it would either diminish and weaken this action of Seeing, or else vtterly extinguish it.

The place of this Vapour.

It is manifest therefore, that in the beginnings of Suffusions, and in Criticall euacuations of Blood by the Nose, in the *Peripneumonia* or Inflammation of the Lungs, in the *Vertigo* or Giddinesse, in the loathing of meat or vomiting, there appeare Gnats and Flyes and certain red shadows called *Marmariga* before the Eyes; all which are not in the externall Aire, for then they should be seene of all Men, but are contained within the Eye. We will therefore thus determine the propounded Question. That some thing within the Eye may be seene, because the obiection is present, that is to say, an interposed Body, a *Medium* transluide which is the waterish humour, and the principall Organ of Sight which is the cristaline humour. Yet we affirme, that this Vision is not perfect. The Reasons which are alleaged for the contrarie opinion, and the Authorities of *Aristotle* are to be vnderstood of perfect Vision.

What we hold

But there is another more obscure Question yet to be resolved, namely, whether that which is within the Eye when it seemeth to be in the outward Aire be seene by a proper *Species* of it owne or by a strange *Species*?

Question.

I answer, that it is by a strange *Species*; for the vapour which is contained betwixt the horny Membrane and the cristaline, is not perceived in the shape and *Species* of a vapour, but vnder another shape contained in the Aire; yet this strange *Species*, when it is receiued into the Eye, it followes the nature, colour, figure and magnitude of that vapour which is already existent in the Eye: So if the internall vapour be greenish or yellow, it represents the *Species* of the externall obiection (as of a Wall or Booke) yellow and greenish; If the vapour be small and diffused, there doe appeare as it were flying Gnats; If it be stretched out at length, Haires doe appeare. Now if that which is in the Eye should be seene by a proper *Species* of it owne, the inner Grapy Coat which is diuers coloured would be seene.

Solution

Finally, the last Knot which remaineth to be vntied is this, Why that which is within the Eye seemeth to be out of it?

Why that which is within doth appeare.

I answer, That the cristaline humor being accustomed to the vision of externall things doth iudge whatsoeuer is within to be without.

Solution.

QVEST. XXIII.

Whether the Organ of Sight be Fierie or watry.

Concerning the nature of the Eyes the *Platonists* and *Peripateticks* are at great strife. *Plato* in *Timao*, because he is perswaded that Vision is performed by Emission of Light from the Eyes, doth therefore thinke that the Eye is of a fiery nature. The Eyes (saith he) doe participate of that Fire which doth not burne, but by illumination doth cheerefully draw the Day out of the Dungeon of the Nights. Now Fire, according to the *Platonists*,

Plato saith, it is fiery.

M m m

is

is three-fold. First, that which doth both shine and burne. Secondly, that which shineth but burneth not. Thirdly, that which burneth but doth not shine. And this opinion of *Plato* *Galen* seemeth to follow in his 10 Booke *De Usu Partium*, and in the 7 *De Placitis Hippocratis & Platonis*. For he calleth the Eye a bright Organ and the Sun-like part of the Creature.

The Platonists
Reasons

The Reasons of the *Platonists* be these. First, the Eyes of some Creatures doe shine and glitter in the Night, as of Night-Owles, and of Cats. Againe, some in vehement fits of Anger haue their Eyes as it were burning and enflamed. Moreouer, when the Eye is shot at one side, we see a kind of fiery glance like Lightning, and the Eye being rubbed in the darke doth yeeld a bright glimpse vnder the Finger. *Aristotle* affirmeth, that *Antiphon* had his own shape and Image continually before his Eyes. And *Pliny* reports many things of *Tiberius Caesar* in the 11 Booke of his Naturall Historie. *Galen* also in the 7 Booke *De Placitis Hipp. & Platonis* maketh mention how it hapned vnto one many Nights before he vtterly lost his Sight, that he perceiued a great quantitie of Light to issue forth of his Eyes. Furthermore, that the Eyes be Fiery may be thus demonstrated, because they are very agile, plyable and mouable: now facilitie of motion is from heat. They are also translucide, of a Pyramidall figure, and full of Spirits, because they performe their functions in a moment. To these we add, that to the most noble *Sensorium* or organ is due the noblest Element, which is the Fire. Againe, the Senses are of the same nature with the things which are subiected to them: but colours are of a Fiery nature, for so *Plato* defines colour to be a flame issuing from the body coloured. Lastly, the Eyes neuer grow stiffe as do other parts of the Body, whence it followeth that they are of a Fiery nature. On the contrarie part, *Aristotle* and all the *Peripateticks* doe contend that the Eye is Watry, but he that desires more satisfaction herein may read those things w^{ch} the same *Aristotle* writ against the *Platonists* in his Booke *De Sensu & Sensili*.

The opinion
of Aristotle
that the Eye
is watry.

The authority
of Hippocrates.

Democritus
Reasons.

We will subscribe rather to this latter opinion, and the same doth Diuine *Hippocrates* affirme in his Booke *De Locis in Homine*, The Sight is nourished by the humiditie of the Braine. Of the same mind also was *Democritus*, as *Aristotle* reports in his Booke of Sense. Lastly, Anatomie and the whole composition of the Eyes doth conuince this. For the principall part of the Eye which first of all causeth Vision, is all Icy, which part being drowned in the glasse humour, hath in the fore-part a Watry humour so disposed for a defence, and if the Eye be hurt or wounded, whatsoeuer doth flow from it is Watry.

Carpentarius
reconciling
Aristotle and
Plato is re-
proued.

Some haue laboured to reconcile *Plato* with *Aristotle* after this manner. There be two things to be considered in the Eyes which concur to this act of Vision. First, a most cleere Visiue Spirit flowing from the Braine through the Opticke Nerves: and secondly, the cristalline humor. Now according to this distinction they say, that in regard of the Spirits and the internall Light, as also of the enlightened object, the Eye is Fierie, but in regard of the cristalline it is Watry. But this distinction seemeth not to be altogether tollerable, for so euerie Organ should be Fiery, because the Organs of all Senses haue their Animall Spirits of the same nature, tenuitie and brightnesse. For there are not diuers kinds of the Animall Spirits, that some should be appointed to the Sight, others to Hearing: I therefore hold it better to affirme simply according to *Aristotle*, and indeed the truth it selfe, that the Organ of Sight is Watry.

The Reasons
of the Platonists
answered

Why the Eye
doth shine.

Concerning those Reasons which are produced in defence of the *Platonists*, they be of small moment; for the Eyes doe shine indeed, and oftentimes a bright splendour doth proceed from them, but not by reason of the Fire, but because of the tralucency, plainnesse and smoothnesse of the Cristalline and the Coats; for whatsoeuer things are smooth and neat doe shine in the darke, as Horne. Againe, it hapneth because the externall Light receiued of the cristalline doth not presently vanish. They are mouable, and for this cause called by the Poet *Faciles*, yet this is not from the Fire, but from an abundant and slippery humidity, from the Spirits and the fixe strong Muscles, by which it is an easie matter for a small Member to be moued.

Why they are
called spiritual

Why not stiffe

They are called Spirituall by reason of their action, for they performe their function in an instant, and because they receiue incorporeall & immateriall *Species* or formes produced and brought through the Aire, and continually offering themselves to the *Pupilla* or Apple. They are not stiffe, yet this is not because they are Fiery, but as *Aristotle* teacheth in his *Problemes*, because they are inuironed with abundance of Fat, w^{ch} Fat though it haue for his efficient cause a defect or weaknesse of heat, yet notwithstanding by a kind of reflection it doth augment the heat, & by his sliminesse doth hinder the ingresse of the Aire w^{ch} beateth vpon them. To these we ioyn the plenty of animall spirits, & the perpetuall motions of the Eyes.

QUEST.

QUEST. XXV.

Wherefore the Eyes be diuersly coloured.

On the other side, that the Eyes are coloured, euen our owne Sense doth teach vs; for some Men are Wall-eyed, some Mens Eyes Blacke, some Mens Sky-coloured, and others Greenish, and so in the rest.

The cause of
the variety of
Colours.
Empedocles.

Aristotle.

M m m 2

appeare

appeare Tawny and splendent. The blacknesse therefore of the Eye is from the plentie and abundance of Humours, the Wall-Eye is from the paucitie and scarcenesse.

Auerroes.

Auerroes thinkes that the whitenesse of the Eye proceeds from coldnesse, because for the most part all white things are cold, as the Braine, the Fat, the Marrow, the Bones, the Membranes: and blacknesse from heat.

Galen opinion.

Galen in the 27 Chapter *Artis Parue*, referres the cause of Colours vnto the plentie, splendor, and scituation of the Christaline and Watry humours. For (saith he) a Wall-Eye commeth by reason of the plentie or splendor of the Christaline, or because of the prominent and bunching scituation, and also the paucitie and puritie of the thin and watry humour. But a blacke Eye comes either from the scarcitie of the Christaline or from the ouer-deepe scituation of it, or because it is not exquisitely splendid and cleere, or because the Watry humour is too abundant, and yet not altogether pure. Thus farre *Galen*.

Auicenna opinion.

Auicenna refers the cause of the varietie of these Colours vnto the Grapy Coat, which as it is diuersly coloured it selfe, so it doth produce diuers Colours in the Eye, a blacke Coat causeth blacke Colour, as a blewish Coat a Colour of the same kind, and his opinion doth *Vesalins* follow.

The first cause referred to the humours.

But to the end that we may reconcile the different opinions of so graue Authors, we doe acknowledge three causes of this varietie: the Humours, the Coats, and the Spirits. The Humours of the Eye are three: first the Watry, secondly the Christaline, thirdly the Glassie. This last because it cannot be perceiued and is placed in the hindmost part of the Eye, doth confer nothing or very little vnto the diuersitie of Colours: but this vertue of alteration and changing the Colour of the Eye dependeth most vpon the Watry & Christall humor. In these Humours also, three things are to be considered: Their Substance, Quantitie, and Scituation. By the name of Substance I vnderstand the puritie or impuritie, the splendor, darknesse, tenuity & density. The Quantity doth note the plenty or scarcity of the humor. The Site is either more hollow and profound, or more prominent and bearing out. There be therefore three causes in respect of the Christaline, of a wally and white Colour in the Eye: First, the plentie of the Christaline: Secondly, the puritie and splendor thereof: And his prominent Situation: for so the Christaline humor by his owne & proper brightnesse illuminateth the Watry humor and the whole Eye. By reason of the Watry humor there be two causes of this Wallinesse, the splendor and the paucitie or scarcitie of it, for a small and pure watry humor doth lesse hinder the Fulgor or brightnes of the Christaline humor.

The cause of Blackenesse.

Obiection.

The causes of blacknesse are quite contrary, as in the behalfe of the Christaline the paucitie or smalnesse of it, his impuritie and deepe situation: and in respect of the watry the impuritie and plentie is the cause thereof. But haply that which *Aristotle* writeth in the 14 Probleme and the 14 Section may seeme to contradict our Assertion, where he saith, the *Ethiopians* haue blacke Eyes, and those that inhabite the *North* white, but in the *Ethiopians* there is lesse plentie of the Watry humor, by reason of that Ambient Aire exiccating or drying vp all things: In those of the *North* it is more abundant.

Solution

I answer, that the Eyes of the *Ethiopians* be blacke, by reason of the paucitie of their visue Spirits (for they are resolu'd and dissipated by the heat) whereby it happens that the light of the Spirits fayling, the Eye appeares as it were darke or ouer-shadowed. But the *Northerne* People doe abound with many Spirits. The Intermediate colours doe depend vpon Intermediate causes.

The second cause of the diuersitie of Colours.

The second cause of the diuersitie of Colours in the Eye may be referred to the Coat called *Membrana*, that is, *Pupilla* or the Grapy Coat, for this onely because it is diuersly coloured, causeth a variegated or diuers coloured Eye. So in the circle of the Eye, which they call the *Iris* or Rain-Bow, diuers Colours doe appeare, because in that part the Grapy Coat is diuers coloured.

The third cause.

Lastly, we thinke that the visue Spirits doe also confer something to the varietie of these Colours; for thin, pure, cleere, and copious Spirits cause whitenesse, but crasse, impure, foggy, and few are the cause of blacknesse. Now that there be Spirits in the Eye is manifest by these Arguments: First, because while the Creature is aliue, the Eye seemes to be exceedingly stretched, neither is any part thereof loose and corrugated, and the one of them being shut, the *Pupilla* or Apple of the other is presently dilated, to wit, because the Spirits passe more plentifully through the Net-like-Coat into the Grapy. Lastly, because sometimes the Eyes appeare languid and obscure, sometimes cheerefull and splendid or bright.

How the Colour of the Eye is changed by the Spirits of the Eye. QV 137.

QVEST. XXVI.

Of the Muscles of the Eyes, and their motion.

Seeing the Eyes be as Scout-Watches, Night and Day watching for our good, it was of necessitie that they ought readily to be moued euerie way, that with facilitie they might be conuerted whither soeuer we would; and to this motion a Nerue of the second Coniugation, and fixe Muscles doe serue. The first whereof lifts vp: The second doth depresse: The third doth draw forward: The fourth draweth backward: And two doe lead the Eye about. By all these performing their functions together, and stretch- ing their Fibres, is the Eye staied and fixed. For it is not (as *Galen* would haue it, and almost all Anatomists following his steps) established or fixed by a seventh Muscle compassing the *Opticke* Nerue, because this Muscle is onely found in Foure-footed Beasts which looke prone toward the Earth lest their Eyes should fall out of their Orbes: which Muscle in a Man is neuer to be found. This motion whereby the Eye is thus firmed, the Physitians call it *Tonicum*, or a set Motion, and it is two-fold, the one *κατὰ φύσιν*, or according to Nature when the Fibres of all the Muscles are equally intended or stretched, so that the Muscles seeme then to be at rest: the other *παρὰ φύσιν*, beside Nature when the Eyes remaine fixt and immo- uable whether we will or no. Which position *Hippocrates* in his Booke *De victus ratione in morbis acutis*, calles a Congelation and Immobilitie or setting and fixing of the Eye. This fixednesse or immobilitie hapneth when the facultie of the Muscles which moue the Eye is resolu- ed, weakned, or wholly extinguished, or because these Muscles are all equally gather- ed or contracted into their heads. This posture of the Eye they call *σκληρὸν εἰσρόπτον*, that is, a ballanced or equall fixing of the Eye, which affect or disease is contrarie to that they call *ἰστρος*, wherein the Eyes haue a wandring and vnconstant staring, as a Horse looks that is full fed; whence also the Disease tooke his name.

There are therefore fixe Muscles of the Eye, not seuen; and of these, foure haue the gouernment of the right motions, two doe obliquely lead the Eye about. And thus may certaine differing places in *Galen* be reconciled, for in his tenth Booke *De Vsu Partium*, he saith, that there are onely foure motions of the Eyes: but in the fourth *De Locis Affectis*, he determines that there be fixe.

Concerning the originall of these Muscles, Anatomists are not all of one mind. Some of them suppose that they spring from the hard *Meninx* within the Scull, but we are of opinion that the foure right Muscles together with that oblique whose Tendon is compas- sed about with the Pully, do arise from that inside of the Orbe which is made by a portion of the Wedge-Bone: and this we are taught, saith my Author, both by experience and by Autopsie or Ocular inspection. But from the Membrane they neither ought nor can haue their originall. They ought not, because a Membrane of an exquisite Sense doth compasse the *Opticke* Nerue, and therefore the Muscles in their motions would compresse this Nerue and so offer violence to the Sight: They could not, because they should not haue adhered to a firme Basis or Foundation.

QVEST. XXVII.

Two obscure and intricate Questions concerning the motion of the Eyes are resolved.

WE will now proceed to discusse a very hard Probleme concerning the motion of the Eyes, the Enodation of which Knots (for ought I know) hath not as yet been performed of any Man. And it is this: Wherefore the Eyes, considering they haue seuerall distinct Muscles by themselves, are yet not moued with diuers motions, but are guided together, and at the same time with one and the same motion. Neither can it be that the right Eye should be moued, and the left stand still; neither can the right be lift vp, and the left depressed, which Identitie of motion is not to be found in any other part of the Body. For I haue free libertie at the same moment to moue my right Hand vpward, and my left downward. *Aristotle* propounds this Question in his *Problemes*, which thus he en- deauoureth to resolu. Though (saith he) the Eyes be double, yet there is but one begin- ning of their motion, and the same originall, to wit, in the Coition or meeting of the *Op- ticke* Nerues. He therefore refers the cause vnto that Coition.

The first Question.

Why the Eyes are moued together with the same motion.

The Solution of Aristotle.

Anicen the Prince of the *Arabians* seemeth to be of the same mind, and *Galen* in his Books of the Use of Parts, where he thinketh the *Opticks* do therefore meet in one, that one object should not appeare double. These things haue some shew of probabilitie, but they doe not giue vs full satisfaction: for the meeting of the *Opticks* doth confer nothing to the motion of the Eyes: the *Opticke* Nerue doth onely see and carie the visive Spirits vnto the *Christalline*, neither is it inserted into the Muscles of the Eye.

Aristotles
answer disa-
lowed our
Reasons

It is onely the second Coniugation which moues the Eyes; in that oppilation or stopping of the *Opticke* Nerue, and in the Disease which the *Arabians* call *Gutta Serena* the action of Sight doth wholly perish, & yet the motion of the Eyes is not a whit hindred; the meeting therefore of the *Opticke* Nerues doth nothing further the motion of the Eyes. Some haue obserued that in many Men who all their life long neuer complayned of their Sight, the *Opticke* Nerues were so framed, that they were continually separated, and did neuer meet together. It is therefore very fond and absurd to thinke that both the Eyes are moued with the same motion, because there is one onely beginning of motion in the meeting of the *Opticks*; seeing neither that Coition nor yet the *Opticks* themselues doe any whit further the motion, but onely the Sense of the Eyes.

The true reso-
lution of the
Question.

We doe acknowledge a double cause of this motion, the Finall and Instrumentall. The Finall cause is the perfection of the Sense. And this is the perfection of the Sense, that the Object appeare euen such as it is; but if the Eyes were moued with diuers motions, that one might be carried down-ward, the other vppward, surely euerie Object, though in it own nature one & the same, yet would continually appeare double, and so the most noble Sense would be deceiued, and the action of Sight would be imperfect. If this seeme harsh to be beleueed, you may thus make tryall of it. If you either lift vp the one Eye, or depresse it with your Finger, you shall see all objects double, and discerne the one to be higher, and the other lower, because the one Eye is moued vppward, the other down-ward. But if you shut either of them, this double apparition of the Object will vanish, although you presse that Eye with your Finger: Also if you moue your Eye to the right Hand or to the left, the object will not appeare double, because the Apples of the Eyes remaine both in one Line.

Question.
Solution.

But wherefore vpon the diuers motion of the Eyes the Objects are doubled, is a thing worthy to be vnderstood. *Galen* in the 13 Chapter of his 10 Booke *De Vsu Partium* writeth, that the Diameters of visible Cones or turbinated formes must be placed in one and the same plaine, least that which is but one should appeare double. For then because the beame of the one Eye doth not equally reach the Object, as neither doth the beame of the other, that which the Sense perceiueth twice, it perceiueth as if it were double or two seuerall things; which also hapneth in the Sense of Touching, for if one Finger be so folded with the other, that it be layd about it, and there-with a Man touch a Stone, the Touch will iudge that to be double which is but one. In the Palsie or the Conuulsion of the Muscles of the Eye, it hapneth that the Objects present themselues in a double forme, because the Eyes depart from the same Superficies: So also the *Opticks* being either loosened or conuelled, the *Pupilla* or Apple doth not retaine his equalitie, whence it commeth to passe that all things appeare double, & so sometimes a drunken Man will thinke all things that he seeth double. In like manner, some that are *Strabones*, that is, Squint-eyed, doe see things double, because one of the *Pupilla's* is either rayfed vp or depressed. But if the Eyes be in the same plaine, though they be two, yet the visible thing is presented simple before them, because the same Species, and the same magnitude at the same time is receiued of both the Eyes, and are together offered to the Common Sense, which doth not discerne any thing but that which is present.

The conclu-
sion.

We conclude therefore, that first in respect of the Finall cause (which as we haue often repeated out of *Aristotle*, is the first and chiefe cause in the workes of Nature) it is that the two Eyes be together and at once moued. I say, this is because it doth much tend to the perfection of the Sense. And Nature doth continually fit her Instruments as they may best further the Finall cause, w^{ch} whether you call the vse or the necessitie it is no great matter. And therefore she hath so disposed the Nerues of the second Coniugation which do carie the command of motion, and the Animall Spirit into the Muscles (which are therefore termed *Porters* and *Cadgers*) that in their beginning they are continuall, making as it were one Chord, whence it is that the right cannot be moued but the other will follow his motion. And this is a new and most elegant obseruation.

The second
question why
the disease of
the one Eye
onely doth
more offend vs

The other Question we discouer out of *Cassius*, to wit, wherefore the Disease of one Eye doth

doth more vex vs then if both were diseased? To wit, because when the one Eye is sound and according to Nature, and therefore is diuersly moued, the sore Eye is also moued there with. Hence it is that the mutuall and equall motion doth exasperate the payned Eye; for when a Member is affected it would haue rest. But if both the Eyes be affected together, the paine becomes more tollerable, for they both rest together, and from that rest they sooner attaine vnto their former naturall disposition.

Solution

QUEST. XXVIII.

Of the humours of the Eyes, whether they be animated parts.

THE Humours of the Eye are three, the Christaline, the Watry, and the Glassie. Of these the Christaline is the principall Organ of Sight, as *Galen* teacheth in the second Booke of his *Method*, in his eighth Booke *De Instr. Odoratus*, the eighth and tenth *De Vsu Partium*, and the first *De Sympt. Causis*. And these Arguments amongst the rest doe euince it: That this Humour is the most cleere and shining of all the rest: That it is seated in the middle of the Eye: That it alone receiueth the *Species* and Images of things: That it onely is altered by colours: And that in it is the concurrence and meeting both of Externall and Internall Light. And therefore when the beating of both the Lights vpon the Christaline is hindred by Suffusions and Obstruction of the *Optickes*, the action of Seeing doth quite perishe, as if a Candle should be extinguished or put out.

The cristaline is the principall Organ of Sight.

Now concerning this Christaline humour, there may three Questions be demanded. First, whether it be a Part. Secondly, whether it be a Similar or Organicall Part. Lastly, whether it performe the action of Seeing by his Temperature or by his Conformation.

That it is an Animated and liuing Part of the Body may be confirmed by Authoritie and also by Reasons. For Authoritie we haue *Galen* in the sixth Chapter of the first Booke of his *Method*, and also in the first Booke *De Sympt. Causis*, accounting the Christaline among the Parts. Reason also perswadeth vs no lesse, for it doth primarily & principally performe the action of Seeing, and actions are not but of Parts onely. Againe, it is nourished, and liueth, and is generated in the Wombe together with the other Parts. It hath moreover his proper Circumscription. And lastly, it is a Body adhering to the whole, and ioyned in the Societie of a common life, framed also and made for the vse and office of the whole.

That the cristaline is a part. Authoritie.

Reason.

But whether it be a Similar or Organicall Part, it is greatly controuerted. Some doe contend that it is not a Similar Part, because, say they, it is neither Bone, nor Gristle, nor Ligament, nor Membrane, nor yet any of those ten which *Galen* describeth in his Booke *De Inaquali intemp. De Elementis & De Temp.*

Whether it be a Similar part.

Contrariwise, it is proued to be a Similar Part in the sixth Chapter of the first Booke of his *Method*, for those, saith he, are called Similar Parts which may be diuided into Parts like themselves, as the Christaline and the Glassie humours in the Eye. And in another place he saith, That in euerie perfect Organ that is a Similar Part which is the beginning and cause of the Action; as in the Eye is the Christaline. But that it is an Organicall Part the situation thereof in the middle of the other Humours, his figure like a Lentile or Fitch, and the magnitude of it doe demonstrate which three are of the Essence of an Organ.

To this I answer, that a Similar and Organicall Part are not opposed one to another. It is no matter therefore whether you call this Christaline a Similar or Organicall Part: For it is Similar, both by reason of his Substance and Temperament, because it is wholly watry, pellucide or bright, and like it selfe in all parts. It is also Organicall by reason of the figure, whereupon *Galen* in his first Booke *De Sympt. Causis*, determines that some of the affects of the Christaline be Similar, as his dry distemper which maketh the disease called *Glaucoma*, and the moyst which makes that affect which they call *Nuxalopia*. Other affects are Organicall, as when it is moued from the naturall situation, vpward, down-ward, to the sides, inward, and outward. Add hereto the greatnesse, littlenesse, and the solution of continuitie. And whereas *Galen* doth make mention onely of ten Similar Parts, he meaneth onely Common Parts, which are found almost through the whole Body: for the Marrow of the Braine, and of the Backe, and the Humours of the Eye are Parts, and yet may not be referred to any of those Ten.

But it is a point of deeper contemplation, and requires more diligent inquisition to know whether the Christaline performe this act of Sensation as it is a Similar Part, or as it is Organicall, that is, whether by vertue of his Temper, or by the meanes of his Figure; yet *Galen* in the sixth Chapter of his first Booke of *Method*, seemeth to refer it to the Temper; for,

Whether the cristaline performe his function by his conformation or by his proper temper.

saith

saith he, the Christaline is the principall Organ of Sight, because it is altered by Colours, and this alteration is from the puritie and brightnesse of it; now the puritie and brightnesse comes from the Temperament. Indeed the magnitude, vnitie, Lentile-like figure of it, and his situation in the midst of the humors are not without vse; but they afford the same helpe vnto Vision that the other Humors and the Membranes doe, that is, they make it more perfect. It is therefore manifest enough by this that hath beene said, that the Christaline humour is a Part.

Whether the
glassy humour
be a Part.

But the Question is more ambiguous concerning the glassie and watry Humour. All the Ancients thought that the Glassie was the nourishment of the Christaline, and the Watry the Excrement of it. *Galen* in the tenth Booke *De Vsu Partium*, writeth, that the Glassie humour turneth into the Aliment of the Christaline; for, saith he, it could not be that the Christaline humour which is white, cleere, and splendent should be nourished by pure and meere Blood, because it doth much differ there-from in qualities; it therefore required an Aliment more familiar and neerer to it owne nature, and this proximitie and familiaritie is in the Glassie humour which is composed by Nature fit to make the Aliment of the Christaline. For this Glassie humour by how much it is thicker then Blood, and more white, by so much doth the Christaline exceed it in humiditie and whitenesse.

That it is a
true part.

But if the Christaline be nourished with the Glassie humour, then cannot the Glassie be an Animated Part, because no Part doth nourish another. Yet *Galen* in the sixth Chapter of the first Booke of his *Method*, nameth the Glassie humour in the Catalogue of the Similar Parts, and in the first Chapter of his tenth Booke *De Vsu Partium*, he thinks that it is nourished by *transmission* or Transumption by the Coat which compasseth it about. If then it be nourished it is a Part.

We suppose the Glassie humour to be no lesse an Animated Part of the Eye then the Christaline, for it hath a proper circumscription, it is generated in the wombe of the purest part of the Seed, it is augmented as the other parts of the Body, it is nourished with Blood, it receiveth Veines from the *Hairy Crowne*, it is couered with a proper Coat, and being once spent it will neuer be recovered.

How the glas-
sie humour
doth nourish
the christaline

They which say the Christaline is nourished with the Glassie humour, doe speake improperly: Indeed it prepareth the Blood for the Christaline by changing it, least the pure Christaline should be infected with a red colour, and with Veines; for it behoued that the Christaline should be deuoid of all colours; yet the substance of the Glassie humour doth not transforme it selfe into the Christaline, nor is assimilated into it. And (saith *Galen* in his Booke of the Eyes) the Glassie humour is affected to the Christaline, as the Stomacke is vnto the Liuer; but the Stomacke doth prepare and minister meat vnto the Liuer as a Cooke, and so doth the Glassie humour to the Christaline.

Aniceni
opinion.

Aniceni thinks that the Watry humour is an excrement of the Christaline, and therefore denyes it to be a Part. Add moreouer, that it is fluide like Blood, and hath no proper circumscription. But we call it a Part, because it continually keepeth the same proprieties of figure, puritie, and quantitie; because it performeth some vse vnto the Christaline, and is as it were a defence vnto it, and like a Spectacle to carry the Images vnto the Christaline: Wherefore *Aristotle* calles it the *Porter* or *Cadger of Images*. This humour also if it should flow out cannot be recovered, and such Effluxion doth wholly extinguish the Sight. But all these properties doe not agree with an Excrement. Moreouer, it is hereby demonstrated that it is not an Excrement of the Christaline, because the Coat called *Arachnoides* or the Cobweb doth intercede or come betweene these two humours.

Aniceni
refuted.

If they obiekt and say that it flowes vp and downe like Blood, and doth not adhere to the whole. I answer, that it floweth when it is out of the Eye, but not at all within the Eye, neither doth it change his place, but is continually contained in a certaine and proper Seat.

QUEST. XXIX.

Of the originall of the Optickes, their meeting and insertion.

Some thinke that this Opticke Nerue is not a whit inferiour to the Christaline humour in dignitie, vse, and necessitie. For *Aniceni* is of opinion that the *Species* and Images of visible things are hereinto receiued. We haue already taught (with *Galen*) that the Christaline humour is the principall Organ of Sight, and that the Opticke Nerue is the conueyer of the visue facultie and the internall Light, to wit, of the visue Spirit.

[But

But that the Historie of the *Optickes* may be made more manifest, there are foure things to be inquired into.

First, what is their originall. Secondly, where their insertion is. Thirdly, how they meet or are conioyned. And fourthly, whether they be hollow.

Concerning their originall and beginning there be diuers opinions. *Auicenna* thinkes they arise out of the forward Ventricles of the Braine: others out of the Center of the Braine: and some out of the After-Braine. We haue obserued, saith *Laurentius*, that out of the lower and hinder part of the Braine, neere vnto the Spinal Marrow, yea out of a part of the Spinal Marrow it selfe, within the Scull, two of the most large and soft Nerues of all the Braine doe arise, that is, the *Optickes*.

Diuers opinions of the originall of the *Optickes*.

They could not arise from the forward Ventricles of the Braine, because there were the Mammillarie Processes: Nor from the middle Basis of the Braine, because this place was appointed for the purging thereof: Nor yet from the After-Braine, because the Sight requireth a verie soft Nerue, but the After-Braine is very hard and not white. The *Optickes* therefore must arise from the lower and hinder part of the Braine, out of each side one, which being obliquely stretched out and separated, doe meet in one almost in the midst of their progresse.

The true opinion.

Concerning this their meeting, two Questions are to be resolued, to wit, how they meet, and secondly, why they meet.

Of the meeting of the *Optickes*.

The manner of their meeting hath not beene knowne till of late dayes: For almost all the ancient Physitians hold, that in their confection they thwart one another like a Crosse, (which thwarting or insertion is called *κρίσις*) and so the right Nerue is carryed to the left Eye, and the left to the right Eye. Others doe not thinke that they thus crosse and intersect one another but onely obliquely touch themselues. But we, saith *Laurentius*, some-thing more accurately and diligently contemplating the manner of this coition or meeting of the *Opticks*, do thinke that the Marrow is mingled and confused in the middle of either Nerue. For if they were onely contiguous touching one another, and not mixed and confused, the *Pupilla* or Apple of one Eye would not so in a moment be dilated when the other is shut. The *Optickes* therefore doe meet and are so mixed in the middle of their passage or iourney, that the one cannot by any Art be seuered from the other. This is the manner of the coition of the *Opticke* Nerues.

The manner of their coition.

Now it behooueth that we looke vnto the Finall cause, namely, wherefore the *Optickes* do meet. First, it was necessarie that they should meet for strength, to wit, that by this coniunction or embracing one of another, they might not suffer any violence in the whole length or tract of their Iourney: For being of all the Nerues the most soft, and creeping so long a Iourney, they would haue beene loose and flaccid, nor carryed in a right line into the *Pupilla* or Apple, vnlesse they had beene vnited in the middle of their passage. So Nature is wont to strengthen those things which are more soft and weake as it were with knots in the midst, as may appeare in the right Muscles of the *Abdomen* or Paunch.

Reason 1.

Secondly, it behooued that they should meet that they might keepe the same plaine and *Superficies* in the Apple: For vnlesse they had thus met they would haue departed from one and the same plaine: So the Eyes being deceiued would haue iudged a simple Obiect to be double: For it behooued (as we haue declared euen now out of *Galen* in the 13 Chapter of his tenth Booke *De Visu Partium*) that the Axes of the Visiue Cones should be placed in one and the same plaine, least the Obiect which is simple and single should appeare double.

Reason 2.

Galen in the 14 Chapter of his 10 Booke *De Visu Partium*, acknowledgeth a third cause of this their meeting, to wit, that the formes and images of visible things may be vnited: For though the *Species* be carryed through two Organs, yet they appeare single and not double. And this was *Aristotles* mind in the first Booke of his *Problemes* and the third Section, where he demandeth why the Eyes are together and at once moued? Because (saith he) they haue one beginning of motion, to wit, the meeting of the *Opticke* Nerues. And *Auicenna* is of the same opinion.

Reason 3.

But I doe not altogether approue of this cause of their coition: For *Resalins* writeth, that he obserued in a young Man, that these *Opticke* Nerues did no where meet, and yet he neuer in the whole course of his life complayned of any deprauation or infirmitie of Sight. *Aristotle* writeth in his second Booke *De Anima* & in the fourth of his *Metaphysicks*, that the Sense is neuer deceiued about his proper Obiect. What need is there then of this coniunction? Againe, if we obtained this by the coition of these Nerues, that the *Species* and formes

Reason 4.

formes of either Eye are vnited into one, then why should not those many things which are seene together appeare but one?

In like manner, though there be two Eares and two Nose-thrills, yet the obiekt doth not appeare manifold to the Sense. It is not therefore from this coition of the *Optickes* that the Obiect appeareth simple, but because the Apples of the Eyes are in the same plaine, and are turned toward the visible Obiect at the same moment.

Reason 4.

Fourthly, some would haue the *Optickes* to meet, to the end they might more fitly proceed out of the perforation in the Scull, and so might be carryed directly to the Eyes.

Reason 5.

Lastly, *Galen* in the 14 Chapter of his 10 Booke *De Vsu Partium*, conceiueth that they meet, that so the Visiue Spirit might passe from the one Eye into the other in a moment for the perfection of the Sight, so the one Eye being shut, we doe see more accurately with the other. And these are all the causes of this coition or meeting of the *Opticke* Nerues.

The insertion
of the Optick
nerues.

Let vs now follow on and declare the manner of their insertion. The *Opticke* Nerue doth consist of a double substance: An internall which is Marrowy, and an externall which is Membranous. The inner Marrow when it attaineth to the Christaline humour is dilated and so diffuseth Visiue Spirits through the whole Eye. Out of this dilatation ariseth a Coat which they call *ἀμφοτέρωθεν* or the Net-like Coat, which (as *Galen* teacheth in the second Chapter of his tenth Booke *De Vsu Partium*) doth neither in colour nor substance deserue the name of a Coat, but if you cast it into Water, you shall see it resemble the soft, white, and Marrowy substance of the Braine. But the outward part of the *Opticke* Nerue doth consist of two Coats, the one is propagated from the thin *Meninx*, the other from the hard; the one is spent into the Grapy Coat, the other into the Horny Membrane: Whence it is, that by the continuitie of this *Opticke* Nerue the Animall spirit is carryed euen in a moment vnto the Apple of the Eye.

Of the cauitie
of the Optick
nerue.

Concerning the last Question, which is of the inner cauitie of the *Opticke* Nerue, *Galen* writeth in the tenth Booke *De Vsu Partium*, that they are manifestly hollow, and therefore *Herophilus* called these Nerues *πόρος*, because they are perforated or holed through. But we doe not admit this sensible cauitie in Nerues, yet we would haue them to be the most soft of all the Nerues, and more spongy, that they might receiue and transport a more copious and abundant source of Animall Spirits.

QUEST. XXX.

whether the Light be the Obiect of the Sight.

Their reasons
which say
Light is the
obiect of sight

Here be some which doe determine that Light is the Obiect of Sight, grounding their opinion vpon this Foundation, because euerie thing which is seene either is Light, or it is seene by the Light, or as *Simplicius* saith, that which is seene is either Light, or neere a Kin vnto it, concluding hence, that Light is visible by it selfe, but colours and other things onely by the meanes of Light, in so much as Light is the cause wherefore they are seene. But none of these are true, and first of all that Proposition may not be granted, to wit, that whatsoeuer is seene is either Light, or is seene by the Light, or is very like to it. For if they take Seeing in so large a sense as to perceiue a thing with the Eyes (as it is necessarie that they must grant, for else we will deny that the Light it selfe may be seene) then would also Darknesse it selfe be seene, which neither is nor may be seene by the Light, neither is it of a nature like vnto it.

Some things
are seene in
the Darke.How the
Starres are
seene

Again, all things are not seene by Light, for there are some things which are made conspicuous onely by Darknesse, but in too cleere and splendide a Light they flye from the Sense, as the Scales and Eyes of Fishes, old rotten Wood, yea I say the Starres themselves, which therefore the Vulgar Imagine doe fall or set because they are obscured by the Light of the Sunne, and so taken from our Sight, but at the returne of the Euening Twylight, to wit, when the Light goeth away, and the Night approacheth, they are by degrees restored to our Sight againe, as in the Morning Twylight they after the same manner doe withdraw themselves by little and little from vs. Therefore euerie thing which is seene is not Light or seene by the Light.

Light is not
the obiect of
the Sight, be-
cause it is in
the Eye.

Reason and *Aristotles* Doctrine doe contradict this opinion: For we are taught by both these, that the Eye should be free from his owne Obiect, that so it may receiue it more sincerely: But the Eye both in regard of his whole frame and composition, and especially in respect of the Christaline humour where the reception of the Obiect is properly made, is especially light and cleere: Light therefore cannot be the Obiect of the Sight.

Moreover,

Moreover, to see, is not onely to know a thing with the Eyes (for this is too large a signification, and agreeth to many things beside the proper Object) but we do properly see that in which (when it is perceived with the Eye) the Sight is determined, and stayeth it selfe. But the Sight is not terminated in the Light, though the Eyes doe perceive it, but reacheth alwayes beyond it. Seeing therefore the Light cannot be truly seene, it cannot be the true Object of Sight.

Furthermore, an incorporeall Object cannot alter a corporeall Organ, except it proceed from a Body, that is, be a qualitie thereof, and then that alteration is attributed to the Body by the meanes of the qualitie; but that Vision be made, it is necessarie that the Organ be altered by the Object; the Light therefore because it is a bare qualitie (though they deny this) is not to be thought the Object of Sight, but some other corporeall Body wherein there is a visible qualitie.

Lastly, the Organ ought to be potentially that which the Object is actually: But the Light is actually incorporeall, and no corporeall Body is potentially incorporeall, vnlesse by the meanes of some actiue qualities, but no such actiue power proceedeth from the Light but illuminatiue and inlightning, which they thinke hath the nature of an Object. But they still object that all visible things must be reduced vnto some primarie Genus, which may be called an Object. Seeing therefore Light is the first of all (because by the helpe thereof other things are seene, but Light needeth no other helpe) therefore worthily all other visible things ought to be referred vnto Light as vnto their primarie and chiefe Genus, and so it remaineth that Light is the first and proper Object of Sight.

But besides that, it is denied that all visible things are seene by the helpe of Sight, as we said before, yet though we should grant so much, it would not follow that all Objects are to be referred vnto the Light, as to their first and chiefe Genus. For visible things are not therefore seene, because they are illustrated and made bright by the Light, but because they haue another affection which can alter the Visiue Facultie. We grant therefore that Light doth necessarily concur vnto Vision, but we deny that it is the immediate cause thereof. Moreover, it is true that those things which moue the Visiue Facultie ought to be reduced to some one principall Genus which is called an Object. Yet all visible things both proper and improper, with all which doe any wayes fall vnder the Sight, cannot be referred vnto any one Genus, and therefore not vnto Light.

The alteration of the organ is requisite to Vision.

The organ ought to be potentially the object.

Whether all objects be referred to the Light, as to the generall

After what manner visible things be seene

QUEST. XXXI.

Of the nature of Light, and what it is.

WE say therefore that the Light cannot moue the Sight, because an incorporeall thing cannot change a corporeall Organ, vnlesse it be disposed and fitted by certain Media or meanes vnto that alteration, but Light hath no actiue power beside Illumination. Against this some oppose and would proue that Light is a Body. First therefore they retort our owne Argument vpon vs. For as we conclude that the Light cannot alter the Visiue facultie; so they infer on the contrarie, that it is therefore a Body because it doth alter the Eye; and that it doth alter the Eye, they conuince by Experience, to wit, because the Light doth trouble the Eyes by mouing and tossing their Spirits, and so causeth some paine and griefe in them, which things cannot be done without alteration, which is proper vnto Bodyes; they therefore by good right conclude that the Light is a Body.

I answer (saith Placentinus) that though a Body be continually requisite vnto alteration, yet that alteration is not of the Body as it is a Body, but as it is such or such a Body, and so qualified; as for example, the Fire doth heat, not as it is Fire, but as it is hot; and as the heat it selfe doth proceed from the Fire, and doth alter cold things which are a good way distant from it, that is, make them hot; so also the Light issuing out of a lucide and cleere Body, doth trouble the Eyes, and produce other effects aboue-named. But as the heat of that Fire is not a Body, but a qualitie of the Body; so also it is not necessarie that this Light be a Body. We confesse therefore that alteration indeed cannot be made without Bodyes, yet this alteration is not to be ascribed to the Bodyes, but to the qualities of the Bodyes. In that therefore the Light doth alter the Eye, it is not because it is a Body, but because it is a qualitie of a Body.

This therefore maketh nothing for them which would haue the Light to be the Object of Sight; for the Light alters the Sight as it is a Light, that is, by illuminating; but this is not

Their reasons which proue Light to be a Body.

That Light doth alter the Eye.

Answer.

not

Answer
to the first.
The Light of
the Sunne is
not ioyned
with the light
of a Candle.

not sufficient vnto Sight; for then heat, cold, humiditie, ficcitie, and other qualities should be the Obiects of Sight, because all these doe alter the Eye.

But beside these Reasons, there be almost innumerable others which doe conuince sufficiently that Light is not a Body, and they are especially drawne from the conditions of Bodies which doe continually and necessarily agree vnto them. For first of all, euery Body is moued in a certaine time and successiue, because of the resistance of another Body; for one Body cannot be moued vnlesse it driue and force another which did before exist in the place to which it is moued; for because Nature doth abhor vacuities or emptinesse, it must needs be that in euery place there must be a Body. But the Light not in any distance of time nor successiue, but in a very moment doth replenish the whole Hemisphere and Horizon by a suddaine diffusion, and doth goe through the whole space from the East vnto the West without any progression of time; whence it doth necessarily follow that it is no Body.

Secondly, euery Body hath his proper circumscription and treble demension, but this circumscription, and these dimensions are not at all competent to Light, vnlesse you will attribute them to the Light in regard of the Body wherein it is, but then it doth agree thereto onely by accident.

To this we will add, that there is no Body in Nature which is not diuisible into infinite Parts; but who could euer diuide the Light?

Moreouer, if it were a Body, some motion which Bodies haue would agree vnto it; for all Bodies are either moued vpward or downward, or circularly; but no such motion can be ascribed to the Light. It followes therefore that it is no Body.

Againe, if it were a Body, it should be either corruptible or incorruptible; but corruptible it cannot be, for then some thing should be generated of his corruption, because the corruption of one thing is the generation of another; but nothing is generated of the corruption of the Light, for if there were it would appeare, seeing the Light is so vast and immense. Neither yet is it incorruptible, for we see that when a Candle is put forth, the Light is extinguished. But if we should grant it to be a Body, how would our Aduersaries auoyd these absurdities which would follow therefrom? Should not there be a penetration of Bodies? For the Light doth penetrate all the parts of the perspicuous Body, and yet the nature both of the Light, and of the Body is preserued whole and entire. Seeing therefore that nothing is more impossible then this penetration of Diameters, as the Mathematicians auouch, it is altogether impossible that Light should be a Body.

Now that we know what this Light is not, it followeth that we make enquire what it is, which that we may obtaine, we will make a reduction into the highest *Genera* or kinds, which are two. For whatsoeuer doth exist in the whole Vniuerse, is either a Substance or an Accident.

A Substance this Light cannot be, for it doth not subsist by it selfe, but if the lucide or bright body be removed, the Light is also taken away: neither can it be separated from the lucide body. Moreouer, no Substance of it selfe is vnder the preception of Sense, but Light is by it selfe perceiued by the Sight: and this no Man can deny, because it is neither knowne by Touching, nor Tasting, nor Smelling, nor yet by Hearing, notwithstanding it is known: It remaineth therefore that the Sight doth iudge of it, and yet it is not therefore the obiect of Sight, as we haue before shewed.

Seeing therefore the conditions of a Substance doe in no sort agree to Light, it is necessarily inferred that it is an Accident; which notwithstanding many vncertaine Wits and ignorant doe deny, grounding themselves vpon this Argument, That if it were an Accident, then Light would mingle it selfe with Light in the same subiect; but it is not mingled, for there doth some distinction appeare betwixt the Light of the Sunne and a Candle when they are both together.

Secondly, they produce an Example of two Candles which make two shadowes out of one darke body; but if the Light of the one should be mingled with the other, and so be made as it were one, they would also onely make one shadow of one body.

But it is not so as they say. For, that the Light of the Sunne is not mingled with the Light of a Candle, doth not happen because it is no Accident, but because these two Lights are not of the same kind, for the one proceedeth from a body more pure and simple, the other from a more impure and materiall substance, so that it seemeth after a sort mingled with Smoake; and as a pure thing vpon an impure rideth aboue and remaineth distinct, least that which

body, but we c
body, yet in a
more darke th
Sight, whence

which is immateriall should be mingled with that which is materiall; so it is impossible that the Accidents of an immateriall thing should be mixed and confounded with those which belong to a materiall body, and this is the Reason why the Light of the Sunne is not mixed with the Light of a Candle.

That which they add of two Candles doth require an other Solution; for the Light of two Candles is of the same kind, but I utterly deny that they are not at all mingled, if this word *mingled* be rightly vnderstood for any mixture or confusion; for the Light of one Candle cannot be discerned from the Light of another but onely by their shadowes; and for this I refer you to your Senses for the tryall, because we treat of a sensible matter; for take two Candles and shew me the Light of the one and of the other, thou shewest the shadowes, and why? Because thou canst not discern the Lights one from another.

But the Reason why two shadowes doe appeare, is, because the Lucide bodies doe send forth their Lights by right Lines, and though their Light be mingled, yet they keepe the rectitude and straightnesse of their owne Lines. When therefore a darke place is opposite to two Lucide bodies, it is of necessitie that it send forth two shadowes, not that the shadow is formed of the Light, but because the darke place is illustrated onely in that part where-against the Lucide body doth directly shine, otherwise hindring the Light that it cannot reach vnto the backe thereof, which therefore casts an obscure shadow. So in the time of the Eclipse, when the Moone for want of Light seemeth to faint away & suffer a *Deliquium*, this hapneth because the Light of the Sunne cannot attaine vnto her according to his wonted manner, by reason of the interposition of the Earth betwixt them. For that obscuritie which is perceiued in the Moone is the shadow of the Earth; for if the shadow it selfe should proceed from the Light, then at Noone-day when the Horizon is perfectly illuminated there could be no shadow at all, because there is no reason why it should be made rather on the one part of the obscure body then on the other; nor why the Light should obscure or cast a shadow from one part of the darke body rather then from the other. But to the matter: I say that the cause why there remaine two shadowes, although the Lights doe mixe together, is the straightnesse of the Lines whereby the Light is sent from a Lucide or bright body into a darke, so that it alwayes leaueth the hind-part thereof darke whence the shadow commeth. And that this is true, it is hereby manifest, because the shadow is moued according to the motion of the Lucide body, as also after the motion of the darke body which casteth the shadow: So that alwayes there is a shadow at the backe-part, and that which lyeth opposite by a right Line against the Lucide body is alwayes enlightened. Yet these two shadowes will not be so obscure as if there were but one, because either of them is much illustrated by the Light of the other Lucide body by which it is not produced. And so much of the nature of Light.

QUEST. XXXI.

Of the difference betweene *Lux* and *Light* it selfe, and *Lumen* or *Illumination*.

Hose which doe peremptorily persist in the defence of the intentionall or imaginarie Essence of Light, hold that *Lumen* or the Illumination and enlightning is a *Species* or kind of that we call *Lux* or the *Light*. For, as the *Colour* and the *Species* doe differ in kind, so in like manner doth the Light it selfe differ from the *Lumen* or enlightning, because as Colours by their *Species* become sensible, so the Light is seene by the Illumination of it as by his *Species* or forme. But we consent not with them: For if Light were seene by Illumination, then this Illumination would not fall vnder the Sense; for the *Species* of sensible things are not themselves perceiued, but they are that whereby the Objects doe moue the Sense: Seeing then the *Lumen* is seene by it selfe, it cannot be that the Light should through it attaine vnto the Sense.

But they further obiect, that the *Lumen* or enlightning is in a Tralucient body, and the Light or *Lux* in a darke body, and that therefore they differ in *Specie* or in kind one from another.

But I answer that it is not so: Indeed we grant that the *Lumen* is in a Tralucient or bright body, but we confidently deny that the Light is in a darke body, for it is also in a Tralucient body, yet in a subiect more dense and darke then that of the *Lumen*, for the Light it selfe is more darke then the Illumination: Therefore saith *Aristotle*, it doth determine or limit the Sight, whence it hath the name of a *Colour*: For he calleth Light white in the Booke De

Answer to the second.

Why there be two shadowes of two Candles together.

The shadow is not from the Light but from the darke Body

The straightnesse of the Lines is the cause why there be two shadowes.

That they differ in kind.

This opinion improued.

Obiection.

Solution

Sensu & Sensili, and also in the fourth Chapter of his first Booke of *Meteors*, he calleth the Sunne white. But the matter is cleere of it selfe: For we perceiue that our Sight is terminated in a Flame, in the Sunne, or in the Moone, neither are any other Colours brought vnto vs through them.

Obiection, that
Lumen is not except

But it may be objected, that Light seemeth to be permanent and abiding in the Subiect, but the *Lumen* is not except in some cleare bright Body.

Answer

I answer, it is true: But yet this doth not argue a Specificall difference: for as the heat being proper vnto the Fire doth abide therein, and the other heat which is produced from this doth vanish when the Fire is removed from it, yet they differ not in kind, so neither doth *Lumen* or enlightning differ from *Lux* or the Fountaine of this Illumination.

That *Lux* and
Lumen do not
differ in kind.

But there be many Reasons why they doe not differ in kind one from another: for some time the *Lumen* or Illumination doth assume to it selfe the nature of *Lux* or Light: So the Moone hath Light which is manifestly nothing else but the very enlightning of the Sunne. But doe they not at all then differ? I say they differ: yet in the Planets not truly but onely in respect. For example: The Moone as it doth enlighten the Earth hath Light: But as it receiue this Light from the Sunne it is onely an Illumination: And hence it is that some Illumination hauing a conuenient darke Body opposed to it will become light and send an Illumination out of it selfe: But if you conceit it without a darke Body it will be onely an Illumination. Euen as the Elementarie Fire in his proper place is commonly called *Lumen* and yet is not seene because it hath no darke Body, that so it may transmit her Illumination to vs: So that Light is no other thing but a condensed Illumination, yet not so that it doth degenerate into a Colour.

Why the Ele-
mentarie Fire
is not seene.

Moreover, they differ in the subiect: for this *Lumen* or Illumination in his proper subiect is *Lux*, that is, a Light: but being without it, it is a meere Illumination, that is, Light is properly called that which is a Lucid or bright Body, as in the Sunne and in other Starres: but Illumination is that which is produced from the Light, so that in the Sunne there is not Illumination but Light, and in the Aire there is no Light but *Lumen* or Illumination onely.

QUEST. XXXII.

That Colour is the Object of Sight.

Colour is the
proper Object
of Sight.

Aristotles
Authoritie.

ALL Authors which euer writ of the Sight, haue determined with one consent, that Colour is the proper Object thereof, herein following the steps of *Aristotle* who hath beene their Leader and Guid: For in the beginning of the seuenth Chapter of the second Booke *De Anima*, he writeth on this manner: *That which is visible is Colour, and this Colour is that which is in it that is visible: And it is visible per se, or by it selfe, that is to say, It hath the cause within it selfe which makes it visible.* Where he not onely describeth the common Object of Sight, but doth presently after restraints it vnto a proper Object, to wit, that which hath the cause of visibilitie (if I may so say) in it selfe: But the cause of visibilitie is to be able to moue the *Perspicuum* or Tralucient body, that is, to imprint his Species in the *Perspicuum*, by the meanes whereof the Sight is moued, and therefore he addeth immediately these words: *All Colour is motiue, or able to moue that which is actually Tralucient, and this is the nature thereof.* If therefore the Colour doe by it selfe moue the Tralucid body, which is the proper cause of visibilitie, it must also be accounted necessarily for the proper Object of Sight: For neither Illumination, nor Light, nor any other thing by it selfe can moue this Sense, vnlesse in some part it be answerable vnto Colours, and then the effect is neuer the lesse due vnto the Colour.

Another
Reason to
proue it.

Add hereto, that the proper Object of Sight must be of that nature, that in it the Sight may be determined, and may there rest to informe the Visiue facultie, and wherein (if need require more accurate inspection) it may stay it selfe. But no such thing can be found in the whole Frame of Nature besides Colours.

Againe, by the Object of Sight all mixt Bodies doe become visible: But this is accomplished neither by Illumination, nor Light, nor by any other thing, but onely by Colours, and therefore they are the proper Object of Sight. It is true indeed, that things are made visible in the Light, yet not by the Light, that is, Light is no sufficient cause of Vision, because it is not able nor apt to moue the Tralucient body, but onely the forme of the *Perspicuum*, for when we say that Colour is able to moue the *Perspicuum*, we doe not vnderstand that

that it is the Act of it, but that it affects and moues it by a visive *Species*, and this is peculiar to Colours alone.

Lastly, all things which be visible doe fall vnder the Sight of the Eyes by the Accidents ^{3 Reason.} which are in them, after the same manner whereby we attaine to the knowledge of any thing by another qualitie: but neither Illumination, nor Light, nor any thing before mentioned is in visible things but onely Colour, therefore we know not things by them but by the Colour.

Seeing then that the Object of Sight ought to be such, that thereby we may come vnto the knowledge of visible things, none of these but onely Colour is to be accounted the Object of Sight, for this is in all things and doth immediately follow the Miftion of Elements.

I might add that in euerie Object there are diuers *Species* to be required, as contrarie, intermediate, and some alike, because there is no election, choyce or dignotion of one simple thing: But there are no differences of Illumination, nor Light, nor of those other things which we haue rehearsed, much lesse are there contrarieties: For Illumination doth not truly differ from Illumination, nor Light from Light; neither is Illumination contrarie to Illumination, nor Light to Light; but there are diuers differences of Colours, and one Colour is contrarie to another; not those therefore but this, to wit, Colour is the Object of Sight.

The variety of kinds is required in every thing.

QVEST. XXXIII.

Whether Colour be Light.

BECAUSE Light as well as Colour doth determine the Sight, and hath in it selfe a cause of visibilitie, hence some thinking that there ought to be but one Object of one knowing and discerning Facultie, haue esteemed Colour and Light to be of the same nature. But this cannot be, for all Colour is not Light, neither is all Light Colour; whereas if they had been of the same nature, they might haue been conuerted reciprocally.

Of one faculty must there bee one object.

But they vrge thus: *Euerie thing which is seene is Colour, but Light is seene, therefore Light is Colour.*

I answer, to be seene may be vnderstood two waies: First, commonly and improperly: so as euerie thing both Colour and that which is proportionable thereunto is said to be seene. And so Aristotle taketh it in the second Booke *De Anima*, and his Chapter *De Visu*, where in the beginning he saith, *That which is visible is Colour, and that which is without name:* As if he should say, *That which is proportionable vnto Colour.* And after this manner Light is seene, and yet is not therefore a Colour, because that on this manner many things may be seene which are not Colour, but onely proportionable vnto Colour.

Secondly, this word *Seeing* is taken properly: and according to this acception nothing can be seene besides Colours.

But they add yet further, that the same effect belongeth to the same cause; but whitenesse and Light doe performe the same effect, for a white Colour doth dissipate the Sight and wearie the Eyes, and the same effect doth the Light worke: Wherefore Light and a white Colour doth not differ.

Objections.

But we deny this Argument: For though there be great affinitie and likenesse betweene whitenesse and the Light, as also betwixt blacknesse and darknesse, yet no Identitie nor vnitie of the *Species* or kind doth hence ensue; for if the case were so, two Lucid bodies would produce Colours of two kinds in one and the same darke Body; because they can neuer shine equally and alike: but to shine were to send forth a Colour. Againe, when the Light fayleth, that is, when darknesse begins to come, first, a greene Colour, then a Purple, and so other intermixed Colours must be induced vpon the darke Body till at length it attaine vnto the quite contrarie Colour, to wit, Blacknesse; euen as the Light doth mediatly and by degrees degenerate into darknesse. But nothing can be more absurd then this: for we see that a white Colour remaineth white, vntill the least part of it may be seen, yea it abideth white till it be so darke that we can see nothing, and all Colours are taken away from our Eyes. Others with more shew of truth haue vndertaken to perswade that Colour is *Lumen* or an Illumination, which opinion they strengthen with no small Arguments. First, because when this Illumination is absent Colours cannot be present: and againe, at his arrivall or returne they are generated in the Bodies.

That colour is an illumination.

But this Argument is of small force, for *Lumen* or Illumination doth not generate Colours in bodyes; neither when it departeth doth it take them away, but is onely the cause wherefore they are sensible when it is present, and being absent are not seene. The reason is, because without this splendor Colours cannot mooue the Tralucēt body, and so the Night doth not take away the Colour, but the Images of it, which are as it were the *Deputies* or in stead of the Colours: but the reall Colours which are by themselves visible, doe remaine, if not actually, yet potentially.

Yet they vrge further, that we see by experience that the Clouds by the diuers irradiation or glittering of the Sunne some-time are of a white and some-time of a red Colour: as also is the Raine-Bow: for which cause also we see the Sea some-time to wax Purple colored, some-time to become gray, and a far off to shew white, and at hand blacke: Finally, the Neckes of Doves, and the Tayles of Peacocks doe wonderfully vary their Colours by the diuers aspect of the Light. But none of these are thus in deed and in truth, but doe so appeare by reason of the vehement splendor of this Sunne, or of the lenitie of the coloured body; whereupon the Sight is some-what hindred that it cannot discern of and know the reall Colours as they are.

Againe, this hapneth not onely from the direct or indirect irradiation of the Sunne, but also from our beholding of the coloured thing from on the right Hand or from on the left, forward or backward: For it is greatly to be respected whether the shadow of the coloured thing be on our side or on the opposite; and therefore according to the motion of the Peacocke so the Colour of her Traine seemeth to be varied: Which thing Painters when they goe about to Limne any Picture doe diligently obserue, marking the place wherein the *Life* is placed, to wit, in what part it doth receiue the Light. Moreouer, they consider the entrance into the place where it is, that they may resolue on what part they may best behold it: well knowing that not onely our Eye, but the Light also should be well disposed vnto the right perception and discerning of the reall Colour. For if a well-painted Picture be placed in an inconuenient place, his forme will not appeare artificiall, but deformed and disordered: not that it is so indeed, but that it onely appeareth so by reason of the inconuenience of the place. And thus also it is with the Colours of Peacocks, so that hence we are taught that the Illumination doth not alter the Colors, but the disordered scituation of the colored body and of him which beholdeth it are a great cause of the variation thereof.

QUEST. XXXIIII.

That the pure Elements are not coloured of themselves.

Perspicuum or Tralucēt body being without all darkenesse can neuer be so condensed that a Color should arise there-from, and therefore the simple Elements, yea and the Heauen it selfe haue absolutely no true Colour: for though the Aire may be so condensed that it may degenerate into Water, yet it will neuer attain vnto a Colour, no nor the Earth it selfe, nor yet that which is more condensed then the Earth. They therefore be in an Error which ascribe whitenesse vnto three Elements, and blacknesse vnto the Earth: Indeed Perspicuitie and Transparencie may be allowed to these three, and a kind of darkenesse to the Earth, but no Colour at all. Notwithstanding, they proue that Colours doe agree vnto the Elements, and especially simple Colours, as white and blacke; because they be simple, and as a mixt body is made of the mixture of the Elements, so say they from the mixtion of white and blacke mixt Colours are generated. And this is their Argument: *That which agreeth to any thing by participation, doth also agree to it by Essence; but both extreme Colours, and those which be intermixed doe agree vnto mixt bodyes by the participation of the Elements: whence they conclude, that it is necessarie that simple Colours, that is, white and blacke doe essentially agree vnto the Elements.*

To which we will answer by denying the Maior Proposition: For many things doe belong to a Body by the participation of another, which may not be attributed to that Body as it is absolutely considered. So to the Elements which are here with vs very turbulent and confused, many things doe agree, which no Man of vnderstanding dare assigne vnto the simple and sincere Elements.

As for example, our Fire which is nothing else but a certaine kindled and flaming smoke, is coloured, perspicuous and bright, but the Elementarie Fire we imagine to be pure and most subtle, from which as from a Fountaine ours doth flow, yet hath none of these grosse qualities

A good

The pure
Elements
are not truly
coloured.

Obiection.

Resolution.

qualities which our Fire hath: For being exceeding subtle and fine it hath no solid Substance admixed with it, and therefore is not affected with any Colour, neither is it Lucid and transparant: For Colour consisteth in such a body as doth determine the Sight, but Light doth not shine in a subtle and thin body, but in a dense or thicke body: We grant therefore for the present, that in mixt bodyes Colours doe result or arise out of the concurrence of the Elements, yet it doth not thence follow that Elements being pure & not defiled with the staine of other compounded matters should be rainted with such Colours as are said to be in the extremities of bodies, as Accidents are in the Subiects; because the second qualities arise from the first, which to ascribe to these simple bodyes were very erroneous: Wherefore the Elements doe not primarily generate Colours in mixt bodyes, but secondarily, that is, not as they retaine their proper nature, but as they lay it aside, and so doe conspire into the nature of the mixt body: For the Elements cannot concur in one & so make a mixt body vnlesse they suffer an alteration both according to their substance and according to their qualitie, and so they doe as it were put off their proper being or Essence, that by this mutuall embracing and coniunction they may produce a compound body. If therefore they neither retaine their substance nor their first qualities (which the Ancients esteemed as their essentiall formes) how should they referue entire to themselves those Colours which are their second qualities that the Colour of the mixt body should proceed from a confluence of the Colours of the simple Elements? Wherefore Colours doe belong to mixt bodyes primarily and by themselves, that is, Essentially and not by participation, and so we will passe by this Argument, not meddling with the Sophistry of their Syllogisme, which euerie one that runneth may perceiue.

How the Elements generate Colours.

QUEST. XXXV.

Of the generation of Colours and of their forme.

WE haue determined already, that true Colours are produced from the Elements mixt among themselves, and not from their first qualities, to wit, the heat, cold, humiditie and siccitie as some haue thought, though in deed almost all second qualities doe consist of these; but Colours doe arise from the Essentiall forme of the Elements, from which forme (as it were a proper Accident) they are deriued, that is; Colour doth arise out of the perspicuitie and opacitie of the Elements proportioned together: For three of the Elements be perspicuous, the Fire, the Aire, and the Water, yet so that the Fire is more transparant then the Aire, and the Aire then Water, onely the Earth is darke: When therefore the Earth is mingled with the three other, it doth determine their perspicuitie, and so induceth a Colour into the mixt body, for their transparency and perspicuitie is condensed and made more crasse and thicke, so that they cease to be tralucen and doe determine the Sight, and then Colour necessarily followeth. For to terminate the Sight in his Superficies is to be coloured, because nothing can determine the Sight but by some Colour: A Colour therefore ariseth from the condensation of a Transparant body by that which is darke in the mition of the Elements; for when the Transparant body by reason of the darke body ceaseth to be transparant, it becommeth coloured, and in his Superficies doth moue the Sight.

The original of Colours.

That which determines the Sight is coloured.

Hence appeareth their Error who suppose a double nature of Colour is signified in that definition which we haue giuen, seeing *Aristotle* calls it, *The extremitie or outside of the Transparant body*; for the extremitie of the Tralucen body is not a Colour, but that which like an Accident doth inhere in the extremitie or Superficies; or if you will, the extreme outside of the *Perspicuum* or Splendent body is not the cause of the Colour, but the Colour produced from elsewhere doth by his adumbration or circumscription determine the transparant Body: For the *Perspicuum* or Transparant body is that, which by reason of the tenuitie of his parts doth transmit the Light and so appeare, yet doth not determine the Sight; where therefore the Sight is determined, there the *Perspicuum* must end: For except it were so the Sight would yet proceed further beyond it; but the Sight is determinated onely by colour and therefore Colour is rightly called the rearme or bond and extremitie of the *Perspicuum*.

Colour is generated of the Mition of the darke body.

What Perspicuum is.

Many are of opinion, that there be no Colours in the darke but onely a kind of facultie and beginning whereof Colours do arise as it were out of a matter illustrated by illumination which serueth in stead of the Forme: Of which Sect *Epicurus* was, as *Laeticius* saith:

Of the forme of Colours.

Lucretius

*Præterea quoniam nequeunt sine luce colores
Esse, nisi in luce existunt primordia rerum.
Scire licet, quo sunt quævis velata colore?
Qualis enim cæcis poterit color esse tenebris?
Lumine qui mutatur in ipso: propterea quod
Recta aut obliqua percussus luce resulget.*

Again, because no Colour can without the Light appeare,
Who shall discern what coloured Maskes the Elements doe weare
Vnlesse the Light doe vnto him their seuerall hewes bewray?
And what Man can the Colours blaze which in blind darkenesse stay?
Because in Light all Colours change, and shine as they are smit
With the Oblique or direct Rayes which from the Light doe fir.

And he maintaineth his opinion by this, that as the coloured Body is illuminated either rightly or obliquely, euen so are the Colours thereof changed. But hauing disputed this before, I now passe it ouer, so that it remaineth that we demonstrate and shew that the *Lumen* or Splendency cannot be the forme of a Colour. But first let vs heare the Argument which the *Epicures* bring in defence of their opinion. They say therefore that *because the faculie of Seeing is one and simple, therefore all things which are indged thereby properly and by themselues, ought to be referred vnto one Primary Genus, and because Light cannot be reduced vnto Colour, it is necessarie that Colour be reduced vnto Light.*

The Epicures
Reasons
that Light is
the forme of
Colours.

But this Reason is so absurd, that it seemeth not worthy the time and labour of confutation, especially because it no whit aduanceth the certaintie of that which is in Controuersie. For they were to conclude, that *Lumen* was the forme of Colours, yet neuer the lesse, their Argument will not stand: for we grant indeed that that which is seene, ought properly and by it selfe to be reduced vnto one *Genus* or head, because the Facultie iudging of them is one as we haue proued before. But we deny that Illumination can properly be seene, or that Colour may be referred there-vnto. Haue we not conuincd by that which goeth before, that whatsoeuer is seene by it selfe is a Colour? Are not Light and Translucency perceiued improperly, to wit, onely as they are proportioned vnto a Colour, as we haue proued sufficiently? And haue we not demonstrated, that neither Light nor Splendency can be a Colour? How then shall Colour be brought vnto the nature of Light? Yea, I maintaine the contrarie, to wit, that Illumination may and ought to be reduced vnto Colour, because it becommeth visible no other way then as it obtaineth some proportion with Colour.

All the objects
of sight ought
to be reduced
to one head.

But in the meane time some doe object, That Colour is said to be actually the extremitie of the Transparent Body, that is, not of the Transparent body as it is Transparent, but as it is an illuminated Transparent body; because without Light both the Colour and Transparent body are onely in Potentia and possibilitie. Seeing therefore that the Light doth enduce an actual being vpon the Colour, it will follow, that Light is the forme of Colour, because the act of a thing is the forme of it.

Light is not
the forme.

How that of *Aristotle*, namely, That Colour is the extremitie of the Transparent body, is to be vnderstood, we haue shewed before: But where it is said, That Light doth actuate Colour, I answer, that Light doth not actuate the Colour as it is considered in it owne nature as a Colour, for a Colour remaineth a Colour euen in the darke: It is true indeed that it maketh the Colour actually visible, neither doe we deny it; but if it were the forme of the Colour it should not onely make it visible, but what Essence so euer Colour hath it should of necessity haue receiued it from the Light: But we haue taught already that the whole Essence of Colour proceedeth from the foure Elements.

The Reason
thereof.

Moreouer, it cannot be that this Light should be the forme of Colours. First, because the forme ioyned with the matter doe constitute one compounded body: But Light and Colours are in diuers subiects.

Again, who euer said that one Accident was the forme of another? But Light though it be some-thing more then a meere Accident, yet it fauours most of an Accident, and therefore cannot be the forme of a Colour.

Lastly, if Illumination were the forme of Colour, then Colours should not differ in *Species*, for whether the Light be strong or remisse, whether it be direct or refract and broken it is alwayes of the same *Species*, but we see that Colours be not onely diuers, but also contrarie, therefore Light cannot be the forme of Colours.

All difference
is taken from
the forme.

But the *Epicures* would make vs beleue, that this varietie of Colours proceedeth from their different originals and beginnings which they esteeme to be their matter. Surely, an opinion

opinion vnbeseeeming one which carrieth but the name of a Philosopher: For can you take the differences of things from their matter? Know you not that the Specificall difference of things doth flow from the forme? Is it any matter which distinguisheth a Man from a Beast? No: but the Vnderstanding or Reason. Now Reason is the forme of a Man, not his matter: And this we may learne by Mechanicall Arts, for the same Workeman out of the same matter doth forme both an Altar & an Image, and these differ one from the other, not because they consist of a diuers matter, but because a diuers forme is giuen to either of them.

To these we will add, that Colours are another thing then the Light. For Colours worke vpon the Light touching the Illuminated Aire, as may appeare in a Looking-Glasse receiuing Colours brought vnto it through enlightened Aire: So also the greenenesse of Trees and Medowes doth appeare in such Bodyes as are opposite vnto them, which could not be except the Colour should worke vpon the Light: But who euer said that the things formed did worke vpon the Forme?

How a Glasse receiueth Images.

QUEST. XXXVI.

Of the Medium or Meane of the Sight.

NO Man euer doubted whether the Sight stood in need of a *Meane*, but all rest vpon Experience, which no Man well in his wits will contradict: for if you lay any Colour vpon the Eye it will not be perceiued, and if that saying of Aristotle be true in any Sense, it is especially true in this Sense of Sight, to wit, that *the sensible thing being layd vpon the Sense doth make no Sensation*. Therefore we ought not to doubt that the Sight hath need of a *Medium*, especially being hereunto perswaded by Reasons besides Experience: For Sight is a spirituall Sense, and therefore cannot perceiue materiall things as they are materiall, but it discerneth their *Species* receiued in the *Meane*, & how could materiall things send forth these *Species* if there were no *Meane* betweene the Object and the Organ? I say, if there were not a *Medium* which might draw out and receiue the *Species* or Formes.

A visible object imposed on the Eyes is not scene.

The Reasons why it needeth a Medium.

It remaineth therefore that we make enquirie what that is which is a competent *Medium* in the Sense of Seeing. First, it cannot be a Body, for euerie Body is either Simple or Compound. A Compound body it cannot be, because all Compound bodyes be coloured, and by consequent are an *Object* and not a *Meane*; neither can any of the Simple bodyes be accounted for a *Meane*, for they be the foure Elements, Fire, Aire, Water and Earth.

No Body is the Meane of Sight. Neither Compound nor Simple.

Fire is no *Medium* for we can see without it, nor yet the Aire because we can see Objects which are in the Water, and this is the reason why the other Elements are not fit for this Function, for a true *Meane* must be in the midst between all visible things, but the Elements are not so, no nor the Heauen it selfe. It followes therefore that none of these may be accounted for the *Meane* of Sight.

It is therefore some Accident which we must resolute vpon to be this *Medium*, as appeareth by that which we haue said; and all Men doe with one consent acknowledge this Accident to be Perspicuity or Transparency, so that we need not to doubt thereof. But because this Transparency as it is an Abstract and an Accident is not sufficient for the performance of this Function, for that the Objects do require a certaine definite affection in the *Medium*, that so they may be carryed to the Instrument, whereby the consent and agreement may be preserved, and that there may be a Connexion and knitting of the Extreames, to wit, of the Object and Organ by the *Meane*: We must therefore find out what it is that doth assist and helpe this Perspicuitie. And this is nothing but the subiect of it, so that we doe not admit simply the Perspicuitie but the Perspicuous body at it is transparant for the true *Meane* of the Sight, that is, not the Abstract onely but the whole Concrete as it hath Perspicuitie in it, so that we are to consider in it both his Matter and his Forme.

Perspicuitie is the true Meane of Vision.

Not Perspicuitie but the Perspicuous body is the object of Sight.

The Matter of the Transparant Body is not one and the same, but diuers and manifold, I say, euerie thing which is peruious and may be perceiued without obstacle or resistance, for the *Perspicuum* seemeth to be deriued a *Perspiciendo* or perceiuing, as a transparant body a *Transparando*, because all things doe transpire and appeare through it. It is therefore nothing else but a kind of substance, not crasse nor dense, but thin, rare and subtile, and especially apt and fit to receiue Illumination and the Colours of other things, as are the Aire and Water, and also many other solid Bodyes, as Glasse, Ice, and such like, as the Philosopher witnesseth in the 68 Text of his second Booke *De Anima*.

The Etymon of Perspicuum

QUEST.

QUEST. XXXVII.

Whether Light be the Forme of that which is Perspicuous.

Whether the
Perspicuum
perish with
the Light.

WE haue taught before that Illumination is the Forme of the Perspicuous body, but because the Light doth very easily recede and goe away so that darknesse doth succeed and easily returne, it may worthily be called in question, whether at the departure of the Light the Perspicuous body doth also perish and cease to be, and is againe generated with the returne of the Light or Illumination.

The Perspicuum
is potenti-
all in the dark.

For my own part that I may speake ingenuously, I am perswaded that it is not corrupted wholly, but onely after a sort seemeth to perish, for whatsoeuer is deprived of his essentiall forme is said to perish. It seemeth therefore that the Perspicuous body may be said to perish when at the receding of the Light darknesse doth ensue: which darknesse is a priuation of that Light which was the Essentiall forme of the *Perspicuum*, I speake of a body actually Perspicuous, because the action, or if I may so say, the actualitie of it ceaseth when the Light fadeth, yet notwithstanding it remaineth in *Potentia* or in possibilitie: for the enlightning doth not induce any subtiltie or tenuitie of the substance: and whatsoeuer is thus perspicuous is also potentially perspicuous in the very darke, for sometimes Darknesse sometimes Light are in Perspicuous bodies, as *Aristotle* saith in the 69 Text of the second Booke *De Anima*, where he defineth a Potentiall perspicuous body.

A doubt
resolved.

But there is yet another doubt of greater weight: For because the Light is an Accident, to wit, a qualitie proceeding from the Lucid body, how can it be the Forme of the Perspicuous body? For to be a Forme of any thing is peculiar to a Substance, how then can that give any Essence or being to another which hath no Essence at all of it owne? For the Light hath no being of it selfe but doth perpetually depend vpon the Lucid body, & therefore how should it give an Essence to the *Perspicuum*? I grant indeed that the Light may be called a qualitie of a Lucid body, yet I deny that it is nothing but a meere Accident: For all Accidents haue their being in some Subiect, and out of the same are nothing: But *Illumination*, though it doe depend perpetually vpon some Lucid body, yet it doth exist out of it, and doth onely in respect differ from that *Lux*, which is as it were the Fountaine of it, as before we haue shewed, and we see that this Illumination is diffused through the whole Hemisphere, which could not be if it were a meere Accident, and had no proper Essence of it owne, for no Accident doth spread so farre from his Originall or Subiect.

Answer

The Essence
of an accident
is in another.
Light is not a
meere accident

We say therefore that *Lumen* out of the Lucid body hath a certaine proper being of his owne, and in that regard is said to be the Forme of the *Perspicuum* or Transparant body, for which cause some call it, *The imitation or resemblance of a Lucid body in a perspicuous Medium*. But as it is in the Lucid body and doth depend vpon it as vpon his originall, it is not without some reason called a qualitie of the same Lucid body.

How the
Light is a
qualitie

Objection.

But some argue against this on this manner: That the Light cannot be the Forme of the *Perspicuum*, because it also receiveth the darknesse into it: If therefore Illumination be the Forme of it, then that which is contrarie vnto it, to wit, darknesse, would in like manner supply the place of a Forme, and so one thing would haue two Formes.

Solution.

But the consequence is false, for though the Perspicuous body doth receiue as well darknesse as Light, yet not after the same manner; for it receiues the one as his Forme, the other as the priuation of that Forme; Light as his Act, and Darknesse as the priuation of that Act. For Darknesse is not contrarie to Light, but a priuation of it, and indeed no other thing but an absence of Light from a Subiect which is fit for Illumination.

What darke-
nesse isAucens
opinion.

But *Aucens* saith, that the Light is not receiued in a Perspicuous but in a darke body and coloured, which body when it is outwardly illustrated, then he thinks that the Perspicuous body is illuminated, and he would haue this Perspicuitie to note nothing else but a priuation of that which hinders the Light, and then that *Perspicuum* is present when there is nothing to hinder the Colour that it might not be illuminated. If then the Light be not receiued in the Perspicuous body, it cannot by any meanes be the Forme thereof.

Refuted.

But though there be many learned Men of this opinion, yet I cannot stay my Iudgment vpon it for some perswasible Reasons which moue me to thinke contrarie. For nothing can passe from one extreame vnto another, vnlesse it passe by the *Meane* which is betwixt them; and it cannot passe through the *Medium* vnlesse it be first receiued into it. Moreouer in a perspicuous *Meane* there appeare diuers effects of Light; for it is attenuated and heated,

heated, which could not be if the Light were not first receiued into it. And by this we may easily gather the insufficiency of *Anicent* conceit. Thus much concerning the difficulties about the Eyes: Now let vs come to the Sense of Hearing.

QUEST. XXXVIII.

Of the Production of a Sound.

Aristotle in the first Chapter of the fourth Booke, and in the sixth Chapter of the sixth Booke of his *Topicks*, saith, That the knowledge we haue of any *Species* dependeth vpon the knowledge of the *Genus*. Seeing therefore that the Voyce is a certaine *Species* of Sound, and as it were an Of-spring propagated there-from, it must needs be that it fauour much of his originall and beginning. Wherefore before we come vnto the knowledge of a Voyce, which is the most particular Object of the Sense of Hearing, it is very necessarie that we premise some-what concerning the Production of a Sound in generall, for by that meanes our knowledge of this Action of the Soule, I meane the Sense of Hearing, will be better guided and perfected.

Why the production of a Sound must goe before the definition.

Wherefore we will first shew you the manner of the Production of a Sound. Secondly, the definition of a Sound. Thirdly, the differences of Sounds. And lastly, we will vnfold some difficulties which may other wise breed scruple in vs. I know well that in other things the plainest way of teaching is to begin with a definition, but because a Sound is, as we say *ens fluxum*, that is, such a *being* as is then onely existent while it is a doing and in the time of his generation, it must needs follow, that when the generation or manner of production is sufficiently knowne, the nature and definition will be better vnderstood. Hence it was that *Aristotle*, when he would deliuer the nature of a Sound, began his Treatise at the manner of Production, and so will we, insisting in his Foot-steps, which although we cannot attaine vnto, yet we will as farre off adore.

As therefore no Sound is made without two Bodyes mutually impeaching or offending one against another, as euen our Sight and Hearing doe sufficiently teach vs, so our Minds also may conceiue, that without the mediation of a third thing, which should be not onely the *Medium* wherein a Concussion is made, but also the materiall cause hauing in it a *Power* of sounding materially, there can no Sound at all by the Concussion of those Bodyes be produced.

Two Bodyes.

Three things required to the production of a Sound

The necessitie of this *Medium* or third Body which must come between in the Collission of two hard Bodyes which make a Sound may be thus demonstrated. If two Bodyes meet one of them must moue and apply vnto the other. Now we know that motion cannot be made without a *Medium*. Againe, that this *Medium* or third Body must haue the facultie of sounding materially therein, is proued, because though two Bodyes offend one against another, yet if they be sharpe or soft they make little or no Sound at all: so a Needle against a Needle, Wooll against Wooll doe not sound. The reason of the first is, because there is no quantitie of this intermediate matter to make an Impression of: The second, because though there be a Collission yet there is no resistance.

A Medium.

Moreover, things that are vnequall or rugged doe not sound well, neither doth a plaine thing make a full sound: For the more cauitie there is in the Body that is beaten (so it be proportionable to the violence that is offered) the more resonant is the Sound. Add hereto, that some-times though the Collission be with greater violence, yet the Sound is not so loud: for two Blockes beaten together will not make so loud a Sound as a little Bell; and when a new piece of Cloath is torne asunder, the rash is louder then if two harder Bodyes should enterfaire one against another. All these instances doe manifestly proue that there is a third thing requisite vnto the production of a Sound, which is also the matter thereof. This third intermediate Body is that wherein the Concussion is made, be it Aire, or Water or Fire: For those three be not onely fit for the Transuection of Sound, but haue also in them the matter whereof it is formed, although not in an equall degree. In Concussions therefore the Facultie of the *Medium* or power of the Matter is actuated when it is intercepted and broken betweene two Bodyes offending one against another.

Many instances to proue that there must be a Medium.

The manner of this interception or fraction is thus: when two Bodyes strike one against another, that which is betwixt them is so vehemently driuen, that one part of it cannot orderly moue by succession after another, but rather one part preuents another, and before the first part hath parted from the place, another is driuen vpon the Necke of it, and so the motion which when it is successively made, is gentle and easie, becommeth now by reason

The manner of the fraction.

instances.

of this inordinate violence tumultuarie and troublesome. Hence it is that soft and acute Bodies make no sound in their Collision, because the stroke that is betwixt them doth not so dispartle or diuide the intermediate Body that there should follow vpon it any interception or fraction, whereby the successiue dissipation may be preuented. Vnequall bodies because in their depressed parts they diuide the Aire as it were into parcels doe yeeld a lesser Sound. Those that are hollow because they gather and close more Aire which is confusedly shuffled and beaten part vpon part, doe yeeld a greater and stronger resonance. Two Blockes beaten one against another doe not sound so loud, because the fraction is not so smart. A Bell and a Clapper because of their hardnesse and polished Superficies doe breake the Aire more suddainly and thoroughly, and so beget a louder and brisker Sound. A new Cloath when it is torne a sunder raseth louder then the percussio of a harder Body, because the Aire which is about it is diuersly distracted into many parts where the many Threds are torne a sunder.

It remaineth therefore that a Sound is made when as two Bodyes offending or iustling one against another, the *Medium* wherein they are moued endureth betwixt them a compression, that compression endeth in attrition, that attrition in fraction, and that fraction kindleth as it were at resonance.

That the fraction
is not
the sound.

Wherefore *Aristotle* said well in the 78 Text of his second Booke *De Anima*, that a Sound is alwayes actuated *when one thing moues against another in a third.*

But although the Aire thus beaten and broken makes a Sound, yet the very fraction of the Aire is not the Sound, neither the next and immediate generation thereof, and herein all Philosophers doe agree, particularly *Auicen*. But what shall we stand vpon Authorities? We proue it thus:

Not the motion.

The Fraction of the Aire is a motion, but the Sound is not a motion: First, because a Sound is the proper Obiect of the Sense of Hearing, but Motion is a common Obiect not discerned by the Sense of Hearing, and therefore a Sound is not a Motion.

Secondly, Motion is no qualitie but reduced vnto other *Predicaments* as we say in Schooles, that is, to *Action*, *Passion*, or *Place*: but Sound is a qualitie, to wit, one of the third kind to which the Obiects of the Senses are referred.

Thirdly, Sound is made by Motion; so we see by Experience; so we are taught by all Philosophy; the same Philosophy teacheth vs, *That nothing produceth it selfe.* Seeing then that Motion produceth Sound, certainly Sound can be no Motion.

Objection.
Solution.

It may be objected that *Aristotle* in the 58 Text of his Booke *De Sensu & Sensili*, and the sixth Chapter saith, that Sound is a Motion. But we answer, that he speaketh not in a formal Sense but a casual, that is, not endeavouring to giue the definition of a Sound, but a casual production, as if he should say, When some Motion is made with such and such circumstances, a Sound will result there-from.

Aristotle's instance.

We will also add another Reason and that very strong, which is on this manner: Those things which haue a particular existence or being one without the other, are in themselves feuerally distinct and diuers. Now the Sound and the breaking motion of the Aire haue feuerall and particular beings, because the Sound is diffused and attaineth to those parts of the Aire or Water, to which parts the Motion cannot reach. And this *Aristotle* in his fourth Booke *De Historia Animalium* proueth by the example of Anglers, who in the time of their disport are as silent as may be, and yet the Fishes heare them. Now saith *Aristotle*, it is not like that their whisperings can produce so vehement a motion that the parts of the Aire broken thereby should by succession moue thorough the whole masse of Water vnto the Sense of the Fish.

That sound is
not immediately
generated
by motion.

Again, that this fraction of the Aire is not the next and immediate generation of the Sound, may thus be euicted: Locall motion of it selfe contendeth or striueth onely vnto *Place*, neither of it selfe doth it make impressio of any other reall *Being*, sauing vpon that which is moued, as *Aristotle* teacheth in the eighth Booke of his *Physicks*, the seventh Chapter and the 59 Text. It followeth therefore, that the generation of Sound is another action besides the motion, which action I know not how to name; yet we may well conceiue a difference betweene the locall impulsio and the Sound, as we may also perceiue that besides locall motion some times heat is engendred, yet no Man will say that motion is the immediate cause of heat. After this manner also we may well conceiue how the influences of the Starres may be dispensed in this inferiour World.

To conclude therefore, it is manifest that there must concur three actions to the production

duction of any Sound, and these three doe each accompanie and succeed other. The first action is the affront which is betwixt the two Bodies which offend one against another. The second is the fraction or breaking of the *Medium*. The third and last is the resonance of that *Medium*, for so you shall giue vs leaue to call it, because we can deuise no other name.

Immediately after this followeth the Sound.

QUEST. XXXIX.

The definition of a Sound.

Having as plainly as we could delivered the manner of the generation and production of a Sound we will now briefly set downe the definition of it. *Aristotle* in the 65 Text of his second Booke *De Anima*, defines a Sound to be a motion of that which may be moued with that motion where-with those things are moued which doe rebound from the mutuall percussio of two Bodies. Others doe define it to be a Sensative quality striking the Hearing and the proper Object of that Sense. But we will thus define it, A Sound is a passie and successiue qualitie produced from the interception and breaking of the Aire or Water which followeth upon the collision or striking of two sounding Bodies, and so fit to moue the Sense of Hearing. If any should object, that there is but one onely nature of one thing, as *Aristotle* saith in the fourth Chapter of his first Booke of *Topickes*, and that a definition is an oration expressing the nature of a thing, as the same *Aristotle* in the fifth Chapter of his first Booke and the sixth Chapter of his fifth Booke of *Topickes* saith, There can be but one definition giuen of one and the same thing. And therefore a Sound should not consist of one Simple, but of a three-fold Nature, because we haue set downe three definitions one differing from another, whereas we promised but one definition in the Title of this Chapter. It is therefore to be considered, that three things may be obserued in all Accidents, and from the knowledge of these their Nature may be better manifested: These are the *Subiect*, the *Genus* and the *Cause*: By which three according to the diuers intention and end of the Definer such Accidents are defined either with the mention of them all, or of the *Subiect* and *Genus* onely the *Cause* being left out, or of the *Cause* alone omitting the other two. The first manner of defining satisfies the Vnderstanding best, the other affords but a lame and defective Vnderstanding of that which is defined.

So in this definition of the Eclipse, that it is a priuation of the Light in the Moone by reason of the interposition of the Earth betwixt the Moone and the Sunne, all three are contained.

Likewise the Thunder defined to be a Sound in a Cloud made by the extinction of Fire, is a definition consisting of all three: But this Thunder is onely defined by the *Subiect* and the *Genus*, if we say, that Thunder is a Sound in a Cloud, and by the *Cause* alone when we say, It is an extinction of the Fire. Now if the nature of Accidents be such, and so great varietie be in their definitions, there is no reason but that a Sound may be described some times one way, and some times another, to wit, either perfectly or imperfectly.

Again, what hindreth that one and the same thing may not some times be defined absolutely, some time relatively, the nature of it being as it were changed vnder the same name or appellation, as it hapneth to a Sound here. It remaineth therefore that there is but one definition of one thing: but if there be more, there is but one perfect and absolute, or else they be all imperfect and defective. Again, one definition is conceived or written absolutely, another relatively.

Let it not then seeme strange to any man that one and the same thing according to a diuers acception thereof, is by *Aristotle* diuersly defined; as also in the first Booke *De Anima*, he defines *Anger* to be an appetite of Reuenge: and presently after, that it is a Feruour or boyling of the Blood about the Heart. Again, he describes a House to be a couer and shelter to defend vs from the violence of Winds and Showres, and also he defines it to be a Worke or Building made of Clay, Stone and Wood: Euen so here when he describes a Sound to be a percussio of one Body against another, it is not formally defined, but by the Efficient cause: so we say, the Eclipse is an interposition of the Earth, that is caused by the interposition of the Earth.

Others defining a Sound say, It is a passie qualitie striking the Sense of Hearing. But we haue added a third (saith *Placentinus*) which notwithstanding I will not discourse of so fully as he hath done, because many things will fall into the following Controuersies.

QUEST.

The definition of a Sound

Objection

A three-fold definition of Accidents.

By the Eclipse

And Thunder

One absolute definition of one accident.

QUEST. XL.

Of the differences of Sounds.

WE desire to know when we treat of any Subject, first, what it is: and then how manifold it is: Wherefore hauing set downe the true definition of a Sound, we will now speake of the differences thereof, which differences because they be drawne from diuers Fountaines and Originals, they are therefore as diuers and manifold.

The difference
of a Sound
from the
Essence,
Graue.

First in respect of their Essence they are thus distinguished: Some Sounds continue long, others endure but a while. Both of these may be thus subdiuided: The first doth either by his long continuance much moue the Sense, or else but a little; and this is called a Graue, Base, or an obtuse Sound. But that which is of a small continuance is diuided into that which either in this short continuance doth greatly moue the Sense, or in the same time doth moue it verie little; and this is called an Acute or trebble Sound, and it is opposite to a Graue or base Sound. And both these haue borrowed their names from tactile qualities which doe properly challenge these names to themselves. An acute Sound hath his name from a sharpe or acute heat or cold; for as these qualities doe easily penetrate any Body, so this acute Sound the Sense of Hearing, which in a short time causeth much Sensation. An obtuse Sound hath his name from obtuse or dull heat and cold, because it doth much resemble them.

Acute.

Obtuse.

And by these may be gathered a manifest difference betwixt a Sound and the Objects of other Senses, for they all doe remaine in the sensible things when the Sensation is past, in which things they actually exist both before and after Sensation, but the Sound doth vanish and goe to nothing, together with the perception thereof. And hence it was that *Aristotle* said, *Some sounding things were onely in Potentia or in Power, and others in Act, &c.*

The Echo

Againe, in respect of the Essence some Sounds are direct, others Reflected, which is called an Echo.

Different
Sounds from
the Essence.

According to their existence some Sounds be in power and possibilitie, others in act.

The formall and inhesiue subiect of potentiall Sounds is in the Aire and Water, but the subiect of an actuall Sound is Iron, Brasse, Siluer, Gold, Stones, Wood, and other hard and smooth Bodyes. And hence doth arise another especiall difference betwixt a Sound & the objects of other Senses, for these do inhere in the Sensible things actually and subiectiuelly, both before, in, and after Sensation: but a Sound doth not exist in any sensible thing actually and subiectiuelly, neither before, nor after, nor yet in the very perception of the same.

Manner of
production

Againe, in respect of the manner of their production: Some Sounds are made by the fraction of the Aire caused by two solid Bodyes, and these Bodyes because they concur vnto the making of a Sound, being distinct either in deed or in some respect, according to their diuers and manifold concursion this kind of Sound is againe distinguished.

The Sound of
Wind.

Some are made by Allision, as when the Aire moued by a vehement Wind doth beat against a solid Body, and of this kind is the Sound when the Lungs doe deliuer ouer the Aire or breath vnto the hard parts of the Rough arterie which maketh a kind of wheezing or whistling.

There ariseth also another kind of Sound when the Aire beateth against other Aire, as it is when the Wind is high, for at such time in the open Fields a Man shall heare a whistling noyse.

Of Cloath

There is another kind of Sound ryfing from Coition: Coition I meane or coniunction of the Aire as when Cloath or Paper is torne, for then to auoyd vacuities the parts of the Aire doe suddainly conioyne at the sides of the Cloath or Paper, where the first parts that are driuen are broken by those which follow and so make a Sound.

Hissing.

There is another kind of Sound made by extention of the Aire, as when in hissing it is driuen thorough the Teeth.

Finally, another by Constriction as in a Pipe or a payre of Bellows, or in Holes or Caues of the Earth where-into the Wind driueth the Aire, and when it is in, sholdreth it as it were into a corner.

Naturall
Sounds

The differences of Sound in respect of the Resonant bodyes are double according to the differences of those Bodyes, to wit, one Naturall, the other Violent. I call that Naturall which is made by such Bodyes as are able from a principle within themselves to make an impression, or to giue a stroke. And this Sound is againe double: The first belongeth to

Animated

animated bodies, the second to those that haue no life. That of animated bodyes is a sound produced willingly by the moouing faculty of the Soule. And it is againe double, that is, made by such organs as are by Nature principally deputed for the production of sounds, or by such organs as are not to that end appointed: The first kinde is yet againe double, One formed by the *Glottis* of expired ayre and is called a *voce*, the other is made of ayre which is not receiued by Respiration, nor formed by the *Glottis*, but by the action of some other body. And of this kinde is the sound of those creatures which wee call *Insecta* and of most Fishes. The Sound that proceedeth from such organs as are not thereto by Nature deputed is also double. First, as when two creatures or two hands do strike one against another, the second when one body hath life, the other hath none, as when a man strikes his hand vpon a Table.

The Voce.

Furthermore, the naturall Sound of bodies without life, is that which is made by the action of the first qualities, as that of the Fire, of the Ayre, of the Water, of the Earth or of these mixed: for example, the thundering of Aire when it is concluded or shut vp in water and violently breaketh forth through a narrow outlet. And thus much of Naturall Sounds. I call that Violent which is made by bodies beaten one against another by an extrinsecall or outward principall, all which might bee nicely parted into seuerall Sections if wee did not thinke that any man might out of the order wee haue before insisted vpon frame vnto himselfe a multitude of distinctions or differences of Sounds.

Violent
sounds

QUEST. XLI.

Of the manner of Hearing.

Concerning the manner of Hearing the Philosophers doe diuersly dissent in their opinions.

Diuers opinions
of hearing.

Alcmaeon thought that wee did therefore Heare because our Eares are empty and hollow within, for all empty things doe make a resonance.

Diogenes.

Diogenes thought that there was a kinde of Ayre within the Braine, and that this Ayre was stricken with the voyce, and this conceit was controuerted in *Hippocrates* times, and therefore in his booke *πρωτον*, he inueigheth against it, *There are* (saith he) *some which writing of the Nature of things haue affirmed that the braine doth make a sound, which cannot be, for the Braine is humid and moist, but no moist body can cause a sound.* *Plato* writeth that Hearing is made by the pulsation and beating of an internall Ayre.

Plato.

But wee passing by these slippery wayes of opinions will insist vpon the true manner of Hearing, and in a short and familiar discourse display the whole Nature thereof. For because the Organ of Hearing was vknowne to the ancient Philosophers and Physitions, particularly to *Aristotle* and *Galen* in whose dayes Anatomy was but in the infancie, and therefore the many small and curious parts of that Organ not found out, we cannot therefore collect the perfect nature of Hearing out of their writings, and therefore in this disquisition wee must trust more vnto our owne experience.

Aristotle in his second booke *de anima* and in his booke *de sensu & sensibilibus*, saith, that three things are required vnto sense.

How hearing
is made.

The object, medium and instrument or Organ; the object of the Hearing is Sound, as colour is the object of the light, but of the Nature of a sound, we haue intreated already as much as is necessary for this place. Onely I will call to your remembrance by the way, that a Sound is a quality arising from the fraction and breaking of the Ayre which is made by the percussion of two hard and solide bodyes, for soft things doe easily yeeld, neither doe they resist the force of that which beates against them.

The object of
it.

What sound,

The medium or meane of Hearing is the externall Ayre, for *Aristotle* doubted whether a voyce could be heard in the water or no, and yet he knows very well that Fishes do heare who was euer present at the fishing for Mullers in the night.

The medium
of it.
The Organ of
it.

The instrument of the Hearing is not the externall Eare, but the internall, which consisteth of foure caviities and many other particles vknowne to the Ancients.

The manner therefore of Hearing is thus. The externall Ayre being stricken by two hard and solide bodyes, and affected with the qualitie of a sound doth alter that Ayre which adioyneth next vnto it, and this Ayre mooueth the next to that, vntill by this continuation and successiue motion it arriue at the Eare. For euen as if you cast a stone into a pond there will circles bubble vp one ouertaking and moouing another: so it is in the per-

The manner
of hearing.

cussion of the Ayre; there are as it were certaine circles generated, vntill by succession they attaine vnto the Organ of Hearing. *Auicen* very wittily calleth this continuation of the stricken Ayre *vndant vocalem*, a *vocall waue*. But this kind of motion is not made in a moment but in succession of Time, wherevpon it is that sound is not presently after the stroke heard from afarre.

The Ayre endowed with the quality of a sound is through the auditory passage, which outwardly is alwayes open, first stricken against the most dry and sounding membrane which is therefore called *Tympanum* or the *Drumme*. The membrane being stricken doth mooue the three little bones, and in a moment maketh impression of the character of the sound. This sound is presently receiued of the inbred Ayre, which it carryeth through the windowes of the stony stone before described, into the winding burroughs, and so into the Labyrinth, after into the Snaile-shell, and lastly into the Auditory Nerue which conueyeth it thence vnto the common Sense as vnto his Censor and Iudge. And this is the true manner of hearing.

QUEST. XLII.

whether the proper and inbred Ayre contained within the Eare be the primary and principall Instrument of Hearing.

HE proper and ingenit ayre which the Barbarians call *Implanted*, and *Aristotle* *inadificated* and *immoneable*, is contained in the second cavity of the Eares, which the same *Aristotle* calleth the *Snaile-shell*. Some doe call it *Immoneable*, because it is not mooued by any other, but alwaies remains the same in the Eares. Others call it *immoneable*, because it hath no naturall sound, but can receiue all the differences of Soundes. The ancients thought that this ayre was the chiefe and principall organ of Hearing, and in respect of this ayre *Aristotle* in his second booke *de anima*, and in his booke *de Sensu et Sensil.* saith, the nature of the Hearing is ayry.

Indeede I esteeme this Ayre to be very necessary vnto Hearing, yea so necessary that Hearing can scarcely be performed without it: but I can neuer perswade my selfe that it is the principall organ of Hearing. It is an vniuersall Theoreme and generally true, that in euery perfect organ there is some certaine particle to which as to the chiefe cause the Action is to bee attributed; so in the Liuer the *vagus nervus* maketh Sanguification, In the Eye the Christaline humour causeth Sight, in the muscles, flesh effecteth motion, and the Mammillary processes doe make the smell. But it will be objected, that this inbred ayre is not a Similar part, therefore no such Action is due to it.

Now that it is no part may be thus demonstrated. Euery Similar part is either Spermaticall or fleshie, but this ayre neither deriueh his Originall from the seede nor from the blood; therefore it is no part. If it bee answered, that it is not indeede a simple ayre but a kinde of spirit. I againe reply, that it cannot be a spirit; for if you conceiue it to bee a vitall spirit, it should not forsake the Arteries: If you say it is Animall, then should it follow that an animall spirit should bee accounted the chiefe instrument in the organs of the other Senses.

Againe, a spirit is the most common organ of the Soule, which that noble forme vseth vnto the performance of all her functions. But as there is a peculiar part in the eye which doth primarily cause vision, to wit, the Christaline humor, a Similar and Spermaticall part generated of the purest portion of the seede: so there must be such a Similar part found in the Eare. But such is not that ingenit or inbred ayre, because it differeth nothing from the outward ayre, but onely in purity and rest. It is generated of the outward ayre, not indeed by coction and elaboration, as are the spirits, nor yet by any action of the Soule, but by the continuall arriuall of new ayre, which partly is brought thorough the hole of the Eares, being alwayes open and winding vnto this Cochlea or Snaile-shell; partly deriued thither, by inspiration thorough a certaine little hole or pipe like a *water-course* opening into the palate.

Moreouer, wee may out of *Aristotle* in the second booke *de Anima*, proue that nothing without life can be the instrument of any Sense: but the inbred ayre is without life or soule, because the Soule is not an act of a simple body. Neither hath this inbred ayre any organs of a soule, for why should this ayre which is only generated by the outward ayre, not concocted by any faculty of the Soule, be rather animated then that ayre which

is in the other cavities of the body. But this Ayre doth *rest* in the Eare, and not in other cavities; because it is concluded in a strait hole; and by reason of the windings of these darke labyrinths cannot easily passe forth.

It is not therefore the organ of Hearing; but rather an internall *Medium*. For as the outward ayre is stricken by the beating of two bodies together, so is the internall stricken by the externall; & that by the interiection of the Tympane, or Drumme, of the Chord or string, and of the three little bones. The same ayre being altered, doth carrie the bare Character and *species* of the Sound separated from the matter, to a nerue of the fifth coniugation, led along and dilated in each Eare. And this nerue is the chiefe organ of Hearing, as the mammillary processes are of the Smell.

It is an internall *Medium*.

Now that this internall *Medium* is required in every Sense, may bee demonstrated by example, for the watery humor is the internall *Medium* of the Sight, the spittle of the Taft, the cuticle or scarfe-skin of the Touch, and the spongie bones of the Smell. In all which the formes are separated from their matter, and being so separated are conuayed to the principall *dispositio* or Organ, that is, the Christalline for the Sight, the Pulpe of the Tongue for the Taft, the Mamillarie processes for the Smell, the true skin for the Touch, and so the Auditorie nerue for the Hearing.

The internall *medium* of all the Senses.

QUEST. XLIII.

An explication of certaine hard Problemes about the Eares.

IT remaineth that wee proceede vnto the dilucidation of some difficult questions concerning the Eares, which knots wee will vntye and explaine for a conclusion of these controuersies. The first thing propounded is, How it comes to passe that *wee are more recreated with Hearing then with Reading*: For wee are wonderfully delighted in the hearing of fables and playes acted vpon a Stage, much more then if wee learned them out of written bookes. *Cardan*, as *Scaliger* saith in his 308 *Exercitation*, contentes himselfe with this onely reason, because, saith hee, those things which are published in bookes are made vulgar and common, and therefore are not so curiously nor with so much delight read ouer; but good Actors are more rare.

Why Hearing in more delightfull then reading

Cardanus.

Scaliger refuteth this argument, both because good bookes are as rare as good Actors, as also because it is not the part of a humane ingenuous disposition but of a liuid and malicious minde, to esteeme those things most precious or more pleasant which are vnknowne to others.

Disproued by Scaliger.

Scaliger therefore presenteth many other reasons of this Probleme. First, because wee learne those things which wee heare with lesse labour then those things which we read.

His reasons.

Secondly, because a voyce doth more affect vs by reason of his inflexion and insinuation into our Sense, whereas reading is onely a dumbe Actor.

Thirdly, because those things which be heard, take a deeper impression in our minds, which is made by the appulsion or ariuall of a reall voyce. But those things which are seene are alwayes intentionally imprinted, and therefore the Act of Seeing is sooner ended and passeth more lightly by the Sense then the Act of Hearing. Whence it followes necessarily that things seene do not sticke so fast vnto vs. And this the Apostle insinuateth when he saith, *Hee beholdeth his face in a glasse and geeth away, and presently forgetteth what manner of one hee was*. Neither is that of the Lyrick Poet any sufficient contradiction of this where he saith:

Segnius irritant animos admissa per aures,

Quam qua sunt oculis subiecta fidelibus.

The voyce that sinkes in by the eare doth not so soone offend

Or gall the minde; as when the eyes more faithfull message send.

For that is true of those things which we doe onely beleue by heare-say, which indeed doe not so neerely affect vs as those things we see done before our eyes.

The fourth reason is, because there is a kinde of society in narration and acting, which is very agreeable to the nature of man, but reading is more solitary.

Fifthly, because a certaine shamefastnesse and obseruancie doth cause vs to apply our eares to him that vttereth any thing by voyce, but in reading there is a kinde of remission in the minde and security from any blame of not profiting. Now wee conceiue more pleasure in a diligent and curious acting, then in a negligent and carelesse.

Sixtly, wee haue opportunity to demaund a reason of some doubts from him which speaketh to vs; and thence we receiue more profit then by bare reading, from which profit a certaine delight doth arise. Againe, because Bookes cannot digresse from their discourse for the better explication of a thing, as those may which teach by their voyce. For in changing of words or mutuall conference, many pleasant passages are brought in by accident, as the Interlocuters list to aduance themselves; as wee see in Comedies it is very ordinary. And by these fauces, as it were, of discourse, is the Hearing more sumptuously feasted, but the vniformity of the stile in things written and the continuity of the sentences causeth the Reader to loathe it.

A second
question.

The second question is, why a mans voyce which is sweeter then the sound of a Pipe, is yet not iudged sweeter by the Eare if a man imitate the sound of a Pipe with his voyce; for when a man sings his voyce is sweeter then a Pipe, but a pipe is more pleasant then a mans voyce when hee whistleth.

Resolution

Some resolve this probleme thus, that it so hapneth because that which is naturall is more pleasant then that which is counterfeited and fained. And therefore when a man sings hee addeth an articulation to his voyce about the sound of a Pipe; wherefore it is not strange that it is iudged to bee sweeter; but when hee imitateth a Pipe or whistleth, it doth not sound so pleasantly as a pipe because hee doth counterfet it.

3. Question.

The third question is why wee do conceiue a song to be more pleasant in consort with a pipe then with a harpe. I answer, because both the sounds are heard distinctly by themselves and better mingled together, for both a mans voyce and the sound of a pipe are accomplished by a breath within, but the sound of a harpe is not so. Againe, it may be thus answered, because a pipe, whose sound is somewhat akin to the voyce, doth drowne many faults in the song, which the sound of a harpe doth not being fine and small and vnfit to consort with the voyce, but is heard distinctly by it selfe carrying his owne tune simple & pure and so discouers all the slips and errours of the song by his owne iust and proportionable harmony. Now seeing that in singing many things happen out of order, that sound which doth most of all bewray the confusion that is betwixt harmony and discord must needs be more harsh in the Eare.

4. Question.

The forth question shall be, why children when they heate musicke doe first cease their crying and after fall asleepe. *Alexander* in the 121. Probleme of the first booke, rendereth this reason of it: because there is a kinde of harmony in the soule by instinct, as other sciences be; neither doe wee obtaine any thing by doctrine as *Plato* affirmeth, but onely by recalling to mind. As often therefore as the soule perceiueth any pleasant melody, she as it were, repeating and calling to mind her owne Nature, causeth the infant to cease crying, and luls it asleepe by drawing it selfe from the trouble of outward obiects.

These are the Platonists arguments.

Aristotle.

But *Aristotle* more truly resolueth this probleme in the 39. probleme and 19. section, where hee demandeth why all men are wont to bee delighted with numbers, tunes and all kindes of musique: Is it because euery thing according to Nature is done by number and measure, that so it might tickle and delight our Senses or our minds? Surely a great argument of the exact and curious disposition of Nature we may finde in our selues, for when we labour, drinke and eate ordinately, that is, according to our proportion (the scantling whereof is most commonly taken by experience) wee doe not onely conserue the naturall disposition and frame of our bodyes, but also increase our strength and perpetuate the vigour both of body and minde: on the contrary, when we liue dissolutely, that is, inordinately, all things runne headlong into detriment. In like manner the resonance or consonance which wee speake of, is, nothing else but an ordinate or proportionable mixtion or temper of contraries amongst themselves, which contraries if they keepe quarter and make, as it were, faire warre, there is a kind of military order or consent in disagreeing. *Aristotle* therefore conceiueth that the consent of words doth therefore refresh, please and delight the Eares, because it is compounded according to certaine lawes deriued or taken from the nature of the thing. Neither is this onely true in the Sense of Hearing, but also in the obiects of the other Senses, for in a picture onely those colours doe delight the Eyes, and in a feast those flavours the Taste, which are tempered after a certaine manner and proportion. *Aristotle* addeth further, that not onely Muscical sounds, such I meane as are made according to art, but those which they call *modi adiecti*, that is, extrauagants, such as wee call voluntaries or the blacke Sants doe oft times delight vs, especially if wee be accustomed vnto them. The

Examples in
our selues.

reason

reason is because custome is another Nature. Wherefore that which is by custome made proportionable is as well musically as that which is naturally melodious.

A fifth question may bee why he that singeth the *Base* is sooner discovered if he make any iarre then hee that singeth the *Treble*: the like happeneth in numbers, for in that which is greater, the error is more evident; but let vs giue the reason. Wee say therefore it is because the base sound consumeth more time, and by that meanes is better perceived by the Eares; but the Treble sound is swift and doth easily and suddainly passe away.

5. Probleme.

A sixth question is, why wee doe not heare well when wee yawne. I answered, that in the act of yawning, (which the Latines call *Oscitation*) wee shake out and disquiet a dull and sluggish winde which lurketh in the cranies and chinke of the throate, which winde attaineth vnto the Eares by those perforations which are made from them into the palate, stoppeth and fullfillet the Organ of Hearing, and withall caueth a kinde of disturbing noyse which darkeneth the brightnesse or dullerth the edge, or adulterates the puritie which commeth from without: so also wee see, that if two men talke together & at once they cannot heare one another, at least not distinctly, because the sound of eithers voice is repelled by the other, and that is the reason why he that would listen & heare distinctly holdeth his breath.

6. Probleme.

Why yawning hinders our hearing.

Add hereto, that the holes of the Eares are compressed when the *mandibles* or iawes are distracted or drawne asunder by oscitation or yawning. If then the hole of hearing be compressed, the aire which carrieth the Sound cannot so freely arrive vnto it.

The seauenth question is, why if a man bee within a house he will sooner heare a noyse that is made without: and on the contrary, he that is without the house shall not perceiue a Sound made within the house? The Reason is thus rendred, Hee that is without doth not so well perceiue the sound that is made within the house, because the ayre breaking forth is dissipated or deuied in a greater roomth or more capacious place, and so the sound becommeth dull and loseth his vigour being parted with the aire into so manie partes, or stretched into so wide an extent. Againe on the contrary, hee that is within the house doth easily heare a noyse that is made without, because the sound entering into the house is contracted, gathered or vnited, and therefore it must needs moue the Sense more fully. The very same reason seemeth to bee in the act of Sight, for being within doores we see better that which is done without, then if we were without doores we should discern what is done within, for the species coming from without into the house are gathered and vnited. Againe, the visue vertue of the eye within the house which vnder-taketh to view that which is without is easily dissipated or disvnited.

7. Probleme.

The eight and last question shall bee, whether when many men talke together they can bee heard further then if one man onely spake, imagining the voyces to bee equall. This question made *Aristotle* at a stand, yet he resolueth it thus in the second probleme of the 19 Section: It is (saith hee) because it is more easie to worke with vnited powers then with single and separate, for all compound things are of greater force then Singulares. Wherefore when many mens voyces goe together, the Sound must needs be constant and vnited, and so drue the aire much further then otherwise it should bee driuen by a single Voice in the same Key.

8. Probleme

A pretie question. Aristotle.

To *Aristotle* wee adde Experience and example. Experience, because you may heare the tumult of an Armie further then the vociferation or crie of one Souldiour.

Experience.

Againe, in Markets & Fayres where many people are assembled, the murmur of the multitude is heard further then the voyce of one man though hee bee lower then his Fellowes. The noise of a Frogge is not great I wis, yet what time they breede they may bee heard many miles out of the Isle of *Elie*. Neither are wee to wonder at this, for wee haue examples of the like in the obiects of other Senses. As many Candles of an equall bignes will enlighten the aire further then one Candle though it be bigger then any of the other. A heap of sand may be seen a great way off on the Seashore, but a moate of sand can scarcely be discerned vnder the eye. If therefore it bee so in the visible obiect, why should we not acknowledge it in the audible? For although the species of particular voices are not vnited, yet where there is a totall aggregatiō or heaping vp of many species together, they may produce one that may attaine to a further limit then any of them could doe in particular.

Examples.

I know well that *Aristotle* in another place, that is to say the 52 Probleme of the eleuenth Section seemeth to contradict that we haue before alleaged out of him, which was the reason

Aristotle contradicts himselfe

reason that I said before *Aristotle* was doubtfull in the resolution of this Question, but because that which we haue quoted is the last, and after-thoughts (they say) are the wisest, we will rest our selues therein: for if we should take occasion to dispute with *Aristotle* too and fro alwaies when we haue occasion offered, we should weary our selues, and forget that our Philosophy is not of the maine, but by the Bye. Wherefore we returne againe to our Anatomy.

QUEST. XLIIII.

Of the wonderfull sympathy and consent of the Eares, the Palate, the Tongue, and the Throttle.

The sympathy
of the eares &
instruments
of the voyce.

Here be many things which doe manifest this wonderfull communion of the Eares with the Instruments of the Voyce, which that *Genius* of Nature *Aristotle* in the 32 Section of his *Problemes* hath declared. For when we would heare any thing attentively we hold our Breath, when we yawne we doe not heare so exquisitely. And if you goad the Tympane of the Eare with an Eare-picker it will presently cause a dry Cough. Those which be halfe deafe doe speake but stuttringly, and their Voyce is made thorough their Nose. Againe, those who from their Birth are Deafe, are in like manner Dumbe. Lastly, if you hold an Instrument in your Mouth or betwixt your Teeth and stop your Eares, you shall heare more perfectly; whence it is that deafe Men doe heare best by their Mouthes. All these are certaine and plaine Arguments of that communion and sympathy which is betwixt the Eares and the Vocall Instruments, to wit, the Mouth, the Tongue and the Throttle.

Whence this
communion is.

But the reason of this communion is not knowne to all: Some thinke, that the Auditorie Nerue, or the Nerue of the fifth Coniugation, and that of the seuenth which moueth the Tongue are couered with the same Coat from their beginning, and therefore the affects of those parts are easily communicated: But Ocular Inspection doth perswade the contrarie, for the passages and wayes of either Coniugation are diuers, and there is a great distance betweene them. We (saith *Laurentius*) will acknowledge a double cause of this communion: The one is referred vnto the Auditorie Nerue, the other vnto a little Canale or Pipe which was vnknowne to the Ancients.

A double
cause of this
communion.

Hippocrates his
community of
vessels.

The Nerue of the fifth Coniugation brancheth out into many Circles, the larger is dilated into the Eare and the Membrane of most exquisite Sense, and carryeth the *Species* or formes of all Sounds vnto the Braine; the lesser runs vnto the Tongue and the Throttle. The affects therefore of the Eares and the Tongue are easily communicated by reason of the communion of the Vessels, which according to *Hippocrates* and *Galen* is the onely cause of this sympathy. Hence it is that the Membrane of the Eare being prouoked or goaded doth cause a dry Cough, whereof *Auicenna* maketh mention of which I spake before. Hence also it is, that almost all deafe Men be dumbe, or at least haue but an imperfect Speech, the Auditorie Nerue being affected, which is complycated or folded with the seuenth Coniugation: For I do not approue of that common Position, that deafe Men be therefore dumbe because they can learne no Language, and because Hearing is the Sense of Knowledge: for if they were onely dumbe for this cause, wherefore should they then sigh and mourne with so great difficulty which are naturall Passions? Why should they not, as well as those which were the first Inuenters of things, faigne Language and words whereby they might expresse the Thoughts and Discourse of their Minds if they could vter them? For Nature hath armed a Man although he be deafe with Reason and Vnderstanding for Inuention.

The second
cause of the
sympathy.

Reasons of
the former in-
stances.

It remaineth that we proceed vnto the second cause of this consent, which is by a Gristly Canale like a Water-pipe, which is conueyed from the second hole of the Eare vnto the Mouth and Palate. This Course or pipe was appointed for the purging of the in-bred Aire, for the auoyding of the Excrements of the Eares, as also that the in-bred Aire might be recreated by the arriual of new Aire inspired by the Mouth; and lastly, that by this way a passage may be open for the externall aire rushing forcibly through the hole of the Eares, as it is in the noyse made by Ordinance when wee are neere it. The Ayre therefore doth passe frelie out of the mouth into the Eare, and againe retireth from the Eare into the mouth. Whence it is, that when wee would heare more attentiuely wee holde our Breath, least the *Cochlea* or *Snail-shell* should be filled with abundance of inspired Aire and so the Tympane bee stretched. But such as yawne doe not heare so well, because in this yawning or gaping the Tympane is so stretched and puffed vp, that it cannot receyue outward Sounds.

Lastly,

QUEST. 45. The sympathy between the eares and Vocall Instruments. 701

Lastly, by scratching the Eare wee prouoke Spittle, because by that comprehending there is an expression of Excrements into the Cartilagineous or gristlelike passage, and so from thence vnto the Tongue. And thus much of the Sense of Hearing, now wee come vnto the Smell.

QUEST. XLV.

What Smelling is.

That the Nose was by Nature made as well for Respiration as for the Sense of Smelling, we haue before declared. But what is the Sense of Smelling, that wee doe vndertake in this place more precisely to vnfold. Smelling therefore is the middle Sense of sense, which perceiveth the odours of things drawne in by the Nostrils for the vse and behoofe of the Creature.

The definition of smelling.

It is a great question (which also wee haue a little touched before) whether to the action of this Sense the Inspiration of aire together with the odour be of absolute necessity; and yet the streame and current of mens opinions as well Philosophers as Physitians run vpon the affirmatiue part. For if wee desire or bee willing to endeavour our selues to Smell any thing more curiously, we draw the ayre in at our Nostriles, and that is the reason why wee cannot smell in the water, because the water that is drawne filleth the passages of the Organ. Placentinus is of the contrary opinion and alledgeth Aristotle for his authour in the fifth Chapter of his Booke *de Sensu & sensib.* where he sayes that Nature doth but collaterally vse Respiration in the Attraction of odours, which Respiration, sayth he, she destined primarily to another end.

Whether inspiration be necessary to smelling.

But if Respiration bee necessary to the Smell, then it followeth that Nature ordayned it primarily for that end. For, sayth hee, this is a rule in Nature, that whatsoever in our bodies doeth necessarily belong to any function that is primarily appoynted for that function, and doth not sort vnto it by error, chance or accident.

Seeing therefore the primary and chiefe vse of Respiration is to refresh and cherish the heart and his spirits, it followeth that it is not altogether necessary for Smelling.

Indeede one and the same thing may haue diuers vses, but the principall and primary vse is but one, for which onely it is necessary and to the rest accommodated onely secondarily or by accident. Againe, if an odour of it selfe bee fit to ascend vnto his owne Organ why should wee thinke that Respiration should bee so absolutely necessary. Now an odour is nothing else but a hot and dry exhalation as we shall proue afterwards, and exhalations of their owne Nature doe tend or moue vpwrd. If then they ascend naturally, why may it not be that a sweet and pleasing breath may rise into the Nostrilles and passe on vnto the Organ of smelling without any attraction of the ayre?

Placentinus addeth another argument which hee called Inuincible, taken from those women that are Hysterically, that is, haue fits of the Mother. For such women although they haue no Respiration at all, doe yet receiue and perceiue odours, and not onely so but are almost miraculously redeemed or recovered by them: what shall wee say vnto the wombe it selfe, doth it not smell? yet no man did euer say that the wombe did respire, and dayly experience teacheth vs that it taketh so great pleasure in sweete Smells and is so offended with that which is noysome and abominable, that it moueth and applyeth it selfe manifestly vnto the one and auoydeth the other, euen with Locall and Mathematicall motion.

Fits of the mother are holpen by smells.

The wombe follows sweet fauours.

But it may bee objected, that if we hold our breath wee cannot smell, and therefore this Sense is not accomplished without Inspiration. Placentinus answereth that it is not true, that if an odour bee applied to the Nose and the breath retayned, no Sense will bee made; and those who vrge experience are deceiued in their experimenting. For the breath cannot bee so retayned that nothing at all should either get in or out. If then any thing enter in it helpeth the attraction of the odour: if any thing get out it hindreth the same, yea it repelleth or driueth it from the Organ. And that the breath cannot bee so immouably retayned, may be conuincied by reason and experience.

Objection.

Salution.

Reason sayth that because such retention of the breath is violent and against nature, Nature will likewise with all his force and vigour resist and oppose that violence, and beside that, all the Organs of Respiration doe by a proper instinct hasten to their Naturall Action.

Hence

Hence it followeth that the Muscles of the brest staggering as it were in their worke of sustentation, and the Lungs declining downward, by their waight doe betwixt them perpetually expell some small quantity of ayre, which is a subtile and fluide Element, and will find way through insensible passages. Now that there is such an instinct in the muscles serving to Respiration, and that this instinct may doe much we may easily coniecture, because though a muscle is otherwise an instrument of voluntary motion; yet even in sleepe when all election is absent, and the will (especially vnto motion) is at rest as well as the body; yet even then the intercostall muscles, and the midriffe which serue for Respiration doe follow the necessity of Nature, and mooue as freely as when we are awake. Shall wee therefore conceiue that vpon the same necessity or a greater, when wee our selues doe voluntarily seeke to oppose and frustrate the end of Nature, shce shall not be able without our knowledge and against our wills to let out so small a quantity of Ayre as may suffice for this her purpose, of Ayre (I say,) which is so subtile and fluid a body that it will issue at the least crannie and yeeld vnto the least impulsion though without violence.

Experience confirmeth the same thing: for if you burne any thing that is odoriferous vnder the Nose and retaine your breath, you shall finde, nay you shall see that that fume will bee mooued on this side and on that side, which no doubt commeth to passe by reason of the Ayre which passeth and repasseth outward and inward: but if it get within the nostrils then it doth presently sent, as any man that list to try may perceiue in himselfe. Indeed some men of no small estimation haue affirmed that wee cannot smell if we retain our breath, but the true reason is, because the odour doth not attaine vnto the Organ, nay it doth not enter into the nostrils, for therein they are deceiued. They thinke they canne hold their breath immouable, whereas indeede the naturall instinct driuing their breath forth, doth also driue the odorable obiekt from the Organ; but let them proue that though a fume doth of it own accord ascend into the cauities of the nostrils, yet it is not perceiued by the Sense of smelling vnlesse they adde respiration thereto, and then I will yeeld them the bucklers.

Question.
Answer. The
conclusion.

You will demand, if Respiration be not necessary, why doe we purposely draw our breath when we would smell.

The answer is at hand, to wit, that the obiekt may sooner and more plentifully attaine vnto the Organ. Wee grant therefore that Inspiration helpeth the Smell much, but it doth not thence follow that it is necessary. Againe, to the maintenance of life Inspiration is absolutely necessary, but for *better life*, not so, but onely by accident or secondarily. In like manner wee confesse that the sense of smelling is not ordinarily without Respiration but yet it may be; and Respiration is not necessary to the being, but to the better beeing of the Sense. And if nature had prepared the way of Respiration through some other member, and not through the Nose; yet vndoubtedly the Nose would haue smelt, as we may see in those creatures which doe not respire. And this is *Cassorius Placentinus* his opinion.

QUEST. XLVI.

Why Man doth not smell so well as many other Creatures.

In *Timaeo*, and *Theophrastus* in the sixth chapter of his sixth booke *de causis Plantarum*, together with many other who haue written of this subiect, all of them, I say, with one consent doe acknowledge that the Sense of Smelling is more dull in men then in many other Creatures.

The same doth *Aristotle* auouch in the fourth chapter of his booke *de sensu & sensibili*, where hee also addeth that of all the senses this Sense of Smelling in man is most sluggish and dull, which also he confirmeth in the 92. text of his booke *de Anima*.

What creatures smell better then men.

The truth of this opinion is very euident by the example of other creatures as Dogges, Hogs, Crowes, Bees and other birds and beasts which are able a farre off to *wind*, as wee say, the sent of any thing. But man is constrained to moue the obiekt euen vnto the Nose, and yet he is not able to discerne or perceiue any smells but those, that are so strong that they alter the Sense either into pleasure or paine. Add hereto, that many brute beasts doe know more by their smels then man can attaine to by all his senses, as the Hound that hunts vpon the cold foote of a Hare or a Deare, yea they can in the night follow a mans steps

Beasts smell many things that men cannot.

steps, and by resending worke out his way through a thousand difficulties and intanglements or permixtion of other Smells. So wee see also in the darke a Dogge will know his owne master from a great many other men onely by his smell. A Tyger being robbed of her whelps will finde them out againe by her smell. Now none of these odoures can the Sense of smelling in man apprehend.

The reason hereof *Aristotle* in the place before quoted referreth vnto the fault, not of the faculty, but of the Organ. For this Organ is cold and very moyst, but the object hot and dry: now it is necessary that the Organ should potentially bee such as the subiect is actually, so that when sensation is made, the object may worke vpon the instrument and conuert it into his nature. But in this Sense of Smelling such conuersion cannot be made without great difficulty, for that which is moyst doth hardly become dry, and by reason of this difficulty a man smelleth but remissly or dully, that is, not without either pleasure or paine. The reason is, because the Object must bee very vehement before it can turne the moysture of the Organ into his owne Nature, that is, make it hot and dry.

The reason
of it.

Beside this proper and natie vnfinesse of the Organ, there is also another ineptitude added; and that is the vicinity or neighbourhoode of the braine, which is in man much greater in respect of his proportion then in other creatures. Seeing therefore the braine aboundeth with moisture, which moisture is also imparted vnto the Instrument of Smelling, it commeth to passe that that Instrument by this coniunction of the braine becometh more vnapt. Whence it is that the same *Aristotle* in the 33. Probleme of the tenth Section, hath obserued that the Instrument of Smelling is much incommodated by the moyst superfluities of the braine. The power therefore of Smelling being as it were steeped in this moisture groweth dull and sleepy, which in that which is hote and dry would bee awaked and shew it selfe; and therefore in brute beasts whose braines are not either so moyst, or at least yield not so much moisture because they are lesse, this Faculty or Sense is more pregnant and apprehensiu.

Other reasons.

Some arguments are neuerthelesse made to the contrary, for thus they say: Where the forme is more excellent, there also the faculty is proportionably excellent. Now wee know that the forme of a man which is his Reasonable soule, is farre more excellent then the Sensatiue forme of a brute beast, wherefore the faculties also of his forme are more perfect, and among the rest that of Smelling.

Objection.

Wee answer, that albeit the Soule of man is much more excellent and diuine then the Soule of a beast, yet so long as it is chained in the prison of this body of Earth, it cannot performe his functions but by the helpe of corporeall Organs, and therefore as the Temperature and conformation of the Organs is more or lesse conuenient, so are the functions more perfect or imperfect. Seeing therefore the Organ of Smelling by which as by a hand the Soule reacheth odours vnto it selfe, is as wee sayd in men somewhat too moyst, and therefore vnfit for the sodaine and quicke reception of odours: it followeth that by reason of this fault of the Instrument the faculty of the Soule is as it were abated or allayed that it cannot so perfectly and freely manifest it selfe.

Solution.

It may be objected againe, that because the Organ of a mans Smell is colde and moyst, hee should Smell the better not more dully, for that which is hote and dry as odours are, doth worke more powerfully vpon that which is the coldest and the moystest.

Objection.

True it is, that the odour will worke better vpon the Organ, but as I said before, cannot so easily conuert it into his owne Nature, for the qualities of the Organ are in a great degree contrary & repugnant to the nature of the Object, but when sensation is made they must grow to be alike. Wherefore if the Organ be so disposed that there is not so great a difference betwixt it and the nature of his object, it commeth to passe that they consent better together, and the Organ yeeldeth more easily toward the Nature of that which doth importune it: But wee proceede vnto the Nature of an Odour.

Solution.

QVEST. XLVII.

Of the Essence of an Odour.

Heraclitus, as *Aristotle* remembreth in the fifth Chapter of his Booke *de Sensu et Sensibili*, conceiuing that Odours are a fumide exhalation, sayeth, that if all Beings had bene fumide the Nose would haue discerned of all. *Aristotle* replies vpon him on this manner. If that were true which *Heraclitus* collecteth, it would follow

Heraclitus opinion of Odours.

Refuted by *Aristotle*

follow that those creatures which liue in the water do not Smell, for in the water there can bee no fumid or smoky exhalations generated. But that Fishes doe smell may bee proued by the choise of their meate, which *Aristotle* perswades himselfe they make by Smelling.

Wee, saith *Placentinus*, haue other Reasons against this opinion: First, because a fumid exhalation is a substance, for it subsisteth by it selfe and sustaineth accidents, and therefore naturally and by his owne motion wee perceiue that it moueth vpward. Now then if an Odour were a fumid exhalation, it could not bee by it selfe sensible, for no substance doth by it selfe fall vnder any Sense. Yet no man will denie but that an Odour doth by it selfe and immediatly worke vpon the Organ of Smelling.

Placentinus re-
futation of
Heracitus.

It is true indeede that a fumid exhalation attayning to the nofethrills mooues the Sense of Smelling, but it doth not follow that therefore such an exhalation is an odour: rather wee should say that the Odour hath his subsistence in the exhalation as in her subiect, for accidents neither are, nor can be without their subiects.

A place of
Galen ex-
pounded.

Notwithstanding there is a place in *Galen* neere the end of the second chapter of his booke *de odoratus organo* which seemeth to prooue this opinion of *Heracitus* to bee true: the words are these; *That falleth into the Sense of smelling which is betwixt the Nature of ayre and water, to wit, such a thing as is neither so thin as aire nor so thicke as water, for that which exhalet or vapoureth from the bodyes of things is the substance of odours, which wee may perceiue by Roses and the like tender plants whose bodyes doe quickly become lesse, crumple and dry vp, whence wee may certainly gather that the more humide part of their substance is resolved in to exhalation.* Thus farre *Galen*.

And answered

Wee answer that *Galen* saith the substance of an odour is an exhalation, by substance there meaning the subiect wherein the odour doth consist, for it had bene a grosse thing in *Galen*, and vnworthy the edge of so keene a Philosopher, if he had attributed substance to an odour which hath no existence of it selfe.

And if any man shall insist vpon the example of Roses, wee will giue him this satisfaction, that *Galen* doth not conclude that Roses therefore doe become lesser and dryer, because their moystest parts are exhaled into odours, but he saith that their moyster part turneth into an exhalation: and hee saith true, for an exhalation which is a substance absumeth the humiditie of the body out of which it issueth, and diminisheth the same, for how can it bee but diminished when a substantiall part is taken from the whole? But an odour is not a substantiall part, neither is it made of a part, but subsisteth in the whole subiect, and is nothing else but an accident or an incorporeall qualitie. So that out of these words of *Galen* wee may gather this excellent point of learning. That where he saith, *That which exhalet from the bodyes of things is the substance of an odour*, hee doth wisely signifie the matter out of which the odour doth arise which is the body, and the subiect wherein it doth inhere which is the exhalation; whereas therefore hee saith that the exhalation is the substance of the odour, he doth not meane that the odour is a substance, but being an accident that it doth subsist in this substance as in his subiect.

A story out of
Plinie.

But for the confirmation of this opinion of *Heracitus* there are some obiections made to prooue that the odour it selfe is a fumid substance, because it performeth many things which cannot be done, but onely by a substance. And first, a creature may thereby bee nourished, for which they alledge *Plinie* in the 2. chapter of his seuenth booke where hee saith that in the Easterne India about the fountaine or head of the Riuer Ganges, there is a nation without mouths, whom he calleth *Astomy*, hairie all ouer their bodyes and cloathed with the leaues of trees. They liue of nothing but exhalations and odours which they draw in through their Noses; meate they haue none nor drinke: onely they vse to smell vpon certaine rootes and flowers and wilde Appels which they carry with them when they trauell farre, that they might not want something to smell to. These men are easily stified with a strong odour.

The *Astomy*.

Democritus

The like wee reade of *Democritus* who they say sustained his life foure dayes with the smell of honey or hot bread. Wee answer that *Aristotle* in the fifth chapter of his booke *de sensu & sensibili*, where he ascribeth this opinion to the *Pythagorians*, that such strange reports are mere fables vnworthy the credite of a history, because they abhorre so much from reason. For those things which do nourish must be conuerted into the substance of the liuing body. Now that which is incorporeall cannot possible be conuerted into a corporeall substance; wherefore odour being of it selfe an incorporeall accident and therefore not changed into the substance of the creature cannot become a nourishment therto, Beside all

Reasons a-
gainst *Plinie*

creatures

creatures haue some place in their bellies which receiue their meate, and from whence the body draweth that which sustaineth it. But the Organ of odours is seated in the head from whence no member of the creature seeketh for nourishment.

They vrge further the example of Cooks, who because they are busie in boyling and roasting viands for other men, doe receiue so many odours from them that they scarce euer are a hungry or desire meate, but rather being satisfied with the smell doe loath the substance, and therefore it is commonly thought that these smells doe satisfy and cloy them. But we deny that this commeth to passe by reason of the odours of meates, but the reason why they desire not meate as other men, is, either because (as it is in the proverbe) they can licke their owne fingers, that is, tasting a little of euery thing they insensibly fill their stomackes; or being alwayes about the fire their pores are opened and the inward heate dissipated which is wont to moue and solcite the appetite, which also is the reason why euery man in winter eats more then he doth in Summer; Or we may say, that they are dried by the heate of the Fire and so become thirsty and drinke often, insomuch that the stomacke being relaxed or loosened by the moisture of drinke becomes languide and so the appetite is broken: or wee may say further, that being very dry they cannot be hungry, because *Aristotle* sayeth it is impossible that at one and the same time a man should vehemently desire both meate and drinke.

It is further objected that as *Aristotle* sayes in the fift Chapter of his Booke *de Sens. & Sensi*, which also is prooued true by experience, that when we are full wee loath the Smell of meates, but delight in the smells of Spices and Roses. If therefore the odour of meate did not nourish, a full stomacke would no more abhorre the odours of meate then of Roses or Spices.

But we answer that this faculty hapneth not because of the odours, but because of the steame or exhalation wherein the odour is; for wee grant that such a steame may in some sort nourish, but the odour of Roses which hath for his subiect a more subtile exhalation is better pleasing vnto vs, especially because their smell is very fragrant and acceptable, whereas the Smell of meates is neuer pleasing but when wee are an hungry. Wee conclude therefore with *Aristotle* in the place before quoted, That odours doe not at all nourish. Others disputing more probably doe make according to *Galen* two kindes of nourishments; one which is taken by the mouth and nourisheth the solide partes of the body; another which is drawne through the Nosthrils which nourisheth the thin & airy parts, as the spirits, for *Galen* affirmeth that the spirits doe feede vpon ayre and odors.

Wherefore the nourishment of the spirits they attribute vnto odours, and the rather are they induced so to thinke because nasty and abominable smells doe make men oftentimes ffound, yea and such exhalations arising from dead Carcasses or muddy fens doe infect the ayre and breede a pestilence. Adde hereto that in the Low Countries the odour that ariseth from the flowers of beanes as they grow in the fieldes, doe often driue travellers into a deliration or light madnesse, as *Leuius Lemnius* hath obserued. And *Plutarch* sayeth that by the smell of oyntments Cats doe grow mad. Moreover, Physicians doe consent that the smell of spices doeth breede *καταπληξια*, that is, a payne or dull stupidity and fulnesse in the head.

Adde hereto that many odours or smells are able to refresh a man when he is ready to ffound or faint away; they exhilarate or cheare the heart, and if we may beleue *Aristotle* in the place before quoted, they correct the distemper of the brayne. All these things wee confesse are true if they be vnderstoode of that vaporious or airy exhalation or substance wherein the odour is transported, for by that meanes or in that respect onely the odour is sayde to nourish the spirites, and *Galen* in his 8. Booke *de compositione medicamentorum secundum locos* and the 4. chapter writeth, that if with the odours there are also many vapours associated, then, sayth he, such odours haue some faculty to nourish. But if we vnderstand by odours the simple object of the smell, naked and separated from exhalations, it is vtterly false that they say; for although that vaporious substance wherein the odor is conuayed doe by the helpe of other qualities concomitating or accompanying the odours cherish and refresh the spirites and performe those other good offices which wee haue remembred, yet it followeth not from hence that an odour is a substance; rather that it is an accident of a substance, because it doth inhere in the forenamed qualified vapour. But we will come vnto the definition of an odour.

Why Cookes
haue no good
stomackes.

Objection.

Solution.

Some say that
odours nourish
the spirites.
Their reasons.

Answers.

QUEST. XLVIII.

The definition of an Odour.

What an odour is.

N Odour is a quality moving the smell, arising out of a fit mixture of the four Elements wherein heate and moisture have the predominance. For we conceive with Aristotle in the fifth Chapter of his Booke *de sensu & sensibili*, that in the pure and sincere Elements there is no odour at all. Aristotle in the beginning of the chapter rendereth the reason, because they can have no Taste unless they be mingled: for the Taste and the Smell, that is, the sapor and the savour or odour doe arise out of the same matter; yet so that in sapsors there is more moisture, in odours more ficcidity: notwithstanding in odours the ficcidity is not at any time without some humour, for those things that wither and are torried do lose their odours, as may appear in the ashes of Juniper, for as soone as all the humour is consumed, the odour or smell vanisheth also therewithall. Again, some that are over-dried recover their smells by the permixtion of moisture.

The drought is predominant in odours.

But that in odoriferous things the ficcidity is predominant, may be proved, because such sweet smelling flowres or what else you shall name, become without smell if they be too much moistened: hence it is, that *Roses* gathered in the raine do smell verie little, nothing at all in comparison of the fragrancie of those that are gathered in faire and dry weather. That also is the reason why in Egypt the flowers are not sweete, because the aire is moist and cloudy by reason of the waters of *Nylus*. On the contrary the hot Climats of the East as *Arabia*, *Syria* and the *Indies* do bring forth Spices and other plants of excellent and delicate Smells. It may be objected there are many waters which are verie odoriferous, now no man will denie but that in water the moisture exceeds the drought. We answer that in water the odour is onely potentiall and that the heate eleuateth or raiseth vp from out of them a vapour or exhalation wherein the ficcidity preuailes over the humidity, and in this vapour is there an Actuell odour. The Reason is, because this mooueth the Sense, but the other odour which is in the water cannot mooue the sense unless it exhale together with the vapour and attaine vnto the organ.

Why in Egypt the Flowers do not smell. Objection.

Solution.

The truth of this we may easily admit if we draw into our Nofethrils a little sweete water, for so we shall not smell the odour thereof, because of necessity a vapour is required to actuate the odour.

Moreouer, that all that odour is potentiall which consisteth not in a vapor but lurketh as yet in mixt bodies, may be convinced by inuincible argument. For Aristotle in the fifth chapter of his Booke *de sensu et sensibili* saith, the subiect of Sapsors and sapsors is one and the same. If therefore in odours or sapsors ficcidity be predominant, in Sapsors or Tasts humidity, it would follow that two contraries should be predominant in one and the same subiect, then which what can be more absurd?

Potentiall Odour what it is.

We must say therefore, that these qualities are in mixt bodies not actually but potentially, and that they arise out of the mixture as out of their matter: so that when we say that ficcidity hath the predominance in odours we speake of that odour which exaleth into acte out of the mixed bodies, and so there shall be no contrariety in that we affirme: neither let any man thinke it absurd, that we say two contraries may be potentially in the same subiect, for water that is tepide or warme, that is, in a middle temper betwixt colde and hot, is potentially both colde and hot at one and the same time, for it hath an equall disposition to them both, and the reason is, because potentiall contrariety breedeth no strife in a Reall subiect.

Heate is the efficient cause of Odours.

A Rule for Herbalists.

Quest. XLIX. Of the Causes of Odours. Although the Nature of an odour doth consist in ficcidity, yet it cannot be at any time without humidity, yea it is generated out of humidity, eleuated or raised vp into vapours by heate: so that there can be no odour unless the force and efficacie of heate doe boyle, rise vp and attenuate the humidity. And this all Herbalists acknowledge for a rule, (to wit) that all things that Smell strongly are hot, so that from the vehemencie or remission of the odour they do in Hearbs distinguish the degrees of heate.

So saith *Aristotle* in the 12 probleme of the 12 Section, strong and ranke-smelling seedes are hotte because the odour proceedeth from Heat. The like also *Galen* affirmeth in the 22. *Galen*. chapter of his fourth Booke *de Simplicium Medicamentorum facultatibus*.

Experience also manifesteth the same, for perfumes are more fragrant when they are Hot then when they are Colde, and in hotter seasons yeelde a sweeter smell; which is an Argument that the moysture is better boiled away, and that there is better plentie of Odour raised vp in the aboundance of exhalations which cannot bee loosened and freed from the bonds of the matter wherein they are vnlesse it bee by heate, for cold doth binde and shut them vp, neither suffering them to yssue out of their substances, nor giuing them way to attaine vnto the organ of sense. And after this manner *Plutarch* in the 25 Chapter of his Booke *de Causis Naturalibus* asloyleth the question, why in a frostie morning Hounds cannot hunt so truely as in open weather.

Sweete things
smell most
when they are
hottest.

why Hounds
cannot hunt
in frost.

But it will bee objected, if the odour bee not a fumide exhalation what neede hath it of moysture and heate which are the causes thereof? Wee must remember that whereof wee were admonished before: That Odours in mixt bodies are onely potentially and cannot bee produced into an acte vnlesse they yssue out of them: wherefore being an accident it cannot yssue out of his subiect wherein it was potentially, vnlesse some other subiect doe accompany it: for saith the Philosopher, the Being of an accident is to bee in. For out of their subiect they are nothing. This subiect therefore which produceth the odours into acte is an exhalation. An exhalation cannot be raised but by heate out of moysture. It followeth therefore that both heate and moysture are necessarie in the production of odors. Necessary, I say, not *per se* as they are odours but *per accidens*, because they cannot actually exist without an exhalation.

Objection.

Solution.

They vrge further, if an odour be of and by it selfe nothing, then there can bee no knowledge thereof, for there is no knowledge of that which is *Nomens* or without being. Againe, a substance *per se* or by it selfe cannot be knowne, and therefore (say they) we take away euen out of the vniuersall Nature all Science, for whatsoever is, is either a substance or an accident, third thing there is none. Indee we grant, that of an odour considered by it selfe and separatedly there is no knowledge, for so considered it is nothing, neither doth it fall vnder Sense, but as it is ioyned with the exhalation it moueth the Sense and also falleth vnder Science or knowledge. In like manner Accidents separated from their substances, and substances separated from the Accidents doe not fall vnder Science, but each by other is mutually knowne and demonstrated.

Objection.

Solution.

No knowledge
of a necessitie
without the
substance.

QUEST. L.

Concluding that Fishes do not Smell.

Some *Peripatetician* (saith *Placentinus*) may object on this manner. If an Odour haue Actuell existence onely in exhalation, so that without it it cannot moue the sense, then what shall wee say to Fishes which liue in the water where there are no exhalations to bee found? For *Aristotle* in the beginning of the fift chapter of his Booke *de Sensu & sensili* saith, that there can bee no fumid exhalation made in water. The reason is, because as soone as ayre is engendred in water it riseth vp out of it in a bubble. Wee may answer, that the Fishes do not liue in the pure and neate element of water, but in a water compounded of foure Elements: being therefore compounded there is some fire in it, Fire alwayes worketh, that worke consumeth moysture, and such consumption is absolved by exhalation or eleuation into vapors.

An objection
of the *Peripatetician*
saith so.

Water consisteth
of foure
Elements.

Seeing therefore, that in water there may be found such evaporation, it may bee happily imagined that by it the Fishes do apprehend Odours.

But (saith my Author) it may bee this thred is too hard twisted, or too finely spun, because first wee must acknowledge that the Fishes smell is wonderfull dull because of the predominance of moysture and colde in the Water. Againe, I doubt it is ridiculous to ioyne Fire and water, two contraries in the same subiect, which is against the law of contrariety.

And surely this blame we should worthily deserue if we should make the Fire and water equall in their degrees. But wee giue the preheminence vnto the water, and say that the Fire as also the other Elements do put their qualities vnder his girdle. I doe not say that

The Fire is re-
mitted not
lost in the
water.

the qualities of the Fire are extinguished or quenched out by the water, but they are remitted or abated, for fire worketh perpetually wheresoeuer it is, and raiseth vapours although they bee neuer so small, for this action necessarily followeth the essentiall forme of Fire; so that if you separate it from the Fire, you take away the whole substance.

Objection.

Some Philosophers are of opinion, that the foure Elements are onely potentiallie in compound bodies, and therefore haue onely potentiall vertues, so that Fire which is onely potentially in water cannot actually worke vpon it. But wee answer, that if the Water bee actually compounded of foure Elements, those Elements must necessarily be in it Actually, for that which is potentially cannot make an Actuell Being or Existence.

Solution.

But yee will say, if the water be mixed with fire, why doth not the fire warme it? Surely it doth warme it although it bee not able to remooue all the coldnesse of the water that it should appeare warme vnto the Touch: or if the water were pure and sincere, it is certaine that it would be much more cold then our water is.

Why well,
Water is
warmed in
Winter.

And this may bee proued by Well waters which are somewhat deepe within the Earth, for they are hotter in winter then they are in Summer; the reason is, because in winter the surface of the earth is condensed or closed vp so that the internall and elementary heate is preserued within the earth, which in Sommer when the face of the earth is loosed and relaxed issueth into the Ayre. Hence also it is that water after it is once heated ouer the fire, will sooner freeze then other which is newly taken out of a Riuer, because in boyling ouer the fire the inbred heat of the water vanisheth the parts being relaxed or disunited, but in fresh spring water the natieue heat remaineth which preserueth it from freezing. Now these things could not be thus, except that fire were actually in the water, and did also actually heate it, Notwithstanding the Philosophers may in some sort be held excused, because the pure elements distinguished feuerally one from another are in compound bodies potentially, for actually pure elements are not in them. But you will say, that because of the fire which is naturally mixed with the water, there is in the water, some little odour, and that little odour Fishes do perceiue. But this cannot be, for man cannot smell in the water, if Fishes therefore could, it would follow that the Sense of Smelling was more perfect in Fishes then in men, which is vtterly false. Neither is it any answer to say that the water hath odors therein: or is odorated in respect of the Siccity, because this Siccity is onely potentiall, and vnlesse the humidity which is actually and predominant there be consumed it shall neuer be able to mooue the Sense, for actuall odour requireth an actuall Siccity, and that actually predominant.

The Philoso-
phers excused

But some man may obiekt that the fire which is in the water, rayseth vp exhalations and so odours. I grant indeede that in water exhalations may be generated, but none such as *Aristotle* vnderstandeth, that is, odoriferous, because those exhalations are meere vapours wherein the Siccity is yet actually overcome by the humiditie. But humide exhalations which are the subiects of actuall odours are neuer found in water, which also *Aristotle* confesseth. Notwithstanding the same *Aristotle* proueth that fishes doe smell, because they make choyce of their meate, as if he should say, that they choose their meat by their Smells.

The difference
betwixt
moyst and
dry exhalations;

But to returne to that wherfrom wee are digressed, and at length to determine this controuerfie, we say, That Fishes may so far forth Smell as the water wherein they liue doth communicate with the Ayre and fire: for seeing nothing can either bee generated or nourished by a simple element, it must needes follow that Fishes being ingendered and nourished in the water, that water partaketh of the vigour and substance of the rest of the Elements. And this is also manifested by the reciprocall transmutation or change of one Element into another, for no man will deny but that rarified water turneth into Ayre, and Ayre rarified into Fire, which could not possibly bee if the water were pure and vnmixed, for it cannot be imagined how it should receiue or put on, a diuers, yea a contrary nature wherewith it hath no affinity or familiaritie.

Fishes cannot
smell in pure
water.

But if any man shall persist and say that the Sea which is the habitation of Fishes, is the pure and sincere Element of water, free from the commixtion of other Elements, then I say, saith *Placentinus*, that Fishes cannot Smell at all. My reasons are, first, because no Sense is mooued but by obiekt, but water which is not adulterated with the mixture of any *heterogeny* body cannot produce an obiekt of smelling, for odours are in that which is dry, now what is more moyst and freer from Siccity, then pure and simple water? Againe, if odoriferous things by too plentiful effusion of moysture doe loose their odour, how can pure and sincere water haue any odour therein? If therefore Fishes doe smell

as *Aristotle* and other classicke authours doe testifie, it must needs bee in regard of the Siccity which commeth from the permixtion of Ayre and Fire.

If any man shall obiekt that water hath no smell in it, because a man cannot perceiue the odour thereof, though hee snuffe it into his Nose, hauing notwithstanding a greater perfection of this Sense then Fishes haue. I answer, that Fishes and those creatures that liue in the water doe smell without respiration or breathing, and without those many helpes of the Organ which are in men.

Fishes smell without respiration.

Moreover, the water being to Fishes a familiar Element, a little odour mixed therewith may moue and stirre vp their senses, whereas in men there must bee a hot steame raised from that which is odoriferous; there must be also Respiration through the Nose to conuay the same steame through the spongie bone vnto the mammillary processes before this Sense in them can be moued.

But whereas *Aristotle* absolutely concludes that Fishes doe smell, because they make choyce of their meate, that consequence we cannot so well approue; for the choyce or election of their meate may proceede from another cause. When wee are to buy any victuals which we may not Taste, wee make choyce by our eyes, beleeuing that that which is best coloured is also best tasted; why should wee not therefore thinke that Fishes may make choyce of their meate by their sight?

How Fishes chuse their meate by their sight.

Againe, all creatures by an instinct of Nature doe desire and seeke after that Aliment which is proportionable vnto them; for what teacheth the Infant in the wombe to drawe vnto it the mothers blood rather then the rest of the humours? Is it the smell of blood? No, thing lesse, for the Infant doeth not smell at all, yea it draweth the nourishment into the Liuer through the vmbilicall veine by a naturall instinct. After the childe is borne what maketh it to choose the mothers milke before all other nourishment? Is it the odour or smell of the milke? No, for we see that when an Infant is laide to the breast, hee suddenly with a kinde of Naturall force laps his tongue about the head of the brest and suckes very strongly. Shall we attribute this worke of the Infant to the Smell rather then to an instinct of Nature? By no meanes, for if you deceiue a childe with a suckling bottle or any such thing like the nipple of the mothers breast, as soone as euer he tastes that which is therein to differ from the Aliment which he naturally desireth, he will presently cry and not be appeased till he haue his mothers brest againe. And thus much shall be sufficient to haue spoken of the causes of odours and some difficulties coincident with them. Now wee proceed to the differences.

By instinct as the infant.

QUEST. LI.

Of the differences of Odours.

To distinguish the particular kinds and differences of Odours, and to giue them proper names is altogether impossible, partly because this Sense is but dull, and partly because of our owne ignorance, which the best Philosophers haue not bene ashamed to confesse.

Differences of odours very nice

Wherefore those that haue written of this place of Philosophy considering how imperfect our Sense is to make fitte distinctions of this obiekt; seeing wee can smell nothing but that which doth vehemently goade and affect the Sense: they haue thought good to distinguish the kindes of odours improperly & by way of translation by the differences of Sapours and Tastes: neither haue they done this without good ground; for betweene Sapours and Sauors, as in the name, so in the nature there is a great affinity, analogy and proportion, insomuch that the odour or saour dependeth vpon the sapour or Taste. So saith *Aristotle* in the fifth chapter of his Booke *de sensu & sensili*, there is no bodie odoriferous which hath not also a strong taste, defining that to be odoriferous or able to moue the sense of smelling, which hath in it power to diffuse a sapid siccity, and a while after he saith, *If therefore any man shall esteeme both (to wit, aire and water) moist, it would follow that odour will be nothing else but Nature of sapide siccity residing in moisture.*

Therefore referred to taste

The kindes therefore of Odours which fall vnder our Sense are these: Biting, Sweete, Sowre, Tart and Fat. As for rotten smells, these (saith *Aristotle* in the place before quoted) are proportionable with bitter Tastes, because as bitter things are hardly swallowed, so rotten or stinking smells are not receiued into the Sense without a kind of regret and loathing. There are two other differences of odours: the first is common to brute beasts

The kindes of odours

and by accident doeth moue pleasure or paine, as those odours which together with the steame do arise from meat, which are pleasant to those that are hungry, and vnpleasant and offensiuē to such as are satisfied.

The other kinde is of it selfe pleasant or vnpleasant, as the smell that breatheth from flowers, and this is proper to men alone, for they doe not prouoke the appetite more or lesse, but rather by another kinde of satisfaction doe dull and appeale it. Yet wee must not beleue that all the differences of Tastes may be applyed to odours, for who euer said that he felt smell?

Finally, Odours are either Naturall or Artificiall; Naturall odours are those which are naturally in the bodies; Artificiall are such as Apothecaries vse to make for pleasure or for Physicke, of the commixtion of many species, and these wee call compound odours, the other simple.

QUEST. LII.

Of the Medium or Meane of Smelling.

The Philoso-
phers opini-
ons.

Confirmed.
What is the
Medium of
Smelling.

The ayre ap-
proved.

The water
questioned.
Aristotle for it.

Placentinus a-
gainst it.

T hath not yet beene called into question whether the smell standeth in need of a Medium or no, all men taking it for granted, that a Medium is required, partly subscribing to that Axiome so often before iterated by vs, That the object immedi- atly touching the instrument maketh no Sensation; partly because in the 97. Text of his second booke de anima, Aristotle speaking particularly of the Smell, hath assigned thereto a deter- minate Medium or Meane, for in that place he doth not onely take away the doubt whe- ther this Sense bee made by a Medium, but withall hee declarerh by what Medium it is ab- solued and perfected. With him therefore (as there is great reason) we also consent. For Odour hauing his residence in a fumid exhalation, with which exhalation the Odour ex- haleth out of the bodies; that vapour cannot accompany the odour vnto the Organ, espe- cially where the distance is any thing great betwixt the body out of which the odour issu- eth and the organ of Sense, but it must be dissipated vlesse it were preserued by some Medium, yet euen that Medium doth not so preserue it, but by degrees it is dissipated and va- nisheth away. Wee conclude therefore that the Sense of Smelling standeth in neede of a Medium. But what this Medium shall be, that, saith Placentinus, I am not resoluēd of; although I am not ignorant, that all Philosophers with one consent doe agree herein with Aristotle, who saith, this Medium is double, to wit, Ayre and Water.

Concerning the ayre, it is without controuersie the Medium of Smelling because when we draw our breath, we do at the same time also Smell, and beside the Odour that exha- leth out of the mixt body, is not diffused into all wayes, but onely that way which the ayre is diffused. A certaine signe that the ayre is both the Medium and the vehicle of Smells.

Concerning the water Placentinus maketh some doubtē, although Arist. in his 2 Booke de anima, and especially in the 8 chap. of his 4. Booke de Historia animalium, doth strue ear- nestly to proue that to fishes, the water is the true Medium of Smelling. His foundation is, that those creatures which liue in the water doe Smell, which if it be so, it is necessary that there must bee also a Medium, wherein the Object shall bee transported. That Medium cannot be Ayre, for ayre as soone as it is generated in water, doth exhale or bubble vp, as the same Arist. teacheth in the 3 chap. of his booke de Sens. et Sensil. from whence he con- cludeth, that for Fishes the water must needs be the Medium. And truly the consequence were certainly and vndoubtedly good, if the foundation and ground where-vpon hee rai- seth it be true. But we haue called that into question before. Now I will adde onely one ar- gument; and that taken from the Nature of a Medium on this manner. All Odour hath his existence in siccity, & therefore requireth also a Medium that is dry, least the Object should loose his odour, for it is the office of the Medium to conferue the Object; but water being moyst is no way fit to conferue the dry Odour, in respect of the contrariety betwixt them, vnlesse a man will bee so bould as to say that one contrary can be the Medium vnto the o- ther, which is as much as if he should affirme that contraries doe not mutually impugne, but cherish and foster one another. Seeing therefore water which is moyst must needs extinguish or dissolve the Odour which is dry, it cannot possibly be a competent Medium for

for it. Hence appeareth the invalidity of *Aristotles* foundation to wit, that Fishes doe Smell. It remaineth therefore that the ayre onely is the *Medium* of Smelling.

QVEST. LIII.

After what manner an Odour affecteth or changeth the Medium.

IT is a great controuersie amongst the Masters of Philosophy, how the odourable Obiect doth change the *Medium*; that is, whether that alteration bee *Reall* or *Intentionall*. *Auerrhoes* impugning *Anicem*, saith, it is done *Intentionally* as a colour is made of that which is coloured, and hee reasoneth on this manner: If the Odour should bee transported through the aire together with a body, then should there bee a penetration of bodies which is impossible to be, and absurd to say. But *Auerrhoes* is deceiued, because an *Intentionall* Obiect cannot really moue the Sense; Now it is manifest that wee Smell really. That which he obiecteth concerning colour, wee haue disputed already in the precedent controuersies. Adde hereto that *Intentionall Beings* are produced from the Soule and doe depend thereon, and therefore they are called *Entia rationis* Notions of reason. By this concession therefore it should follow, that the Obiect is in the vnderstanding before it is in the Sense, if it were true that a *Reall* obiect did make an impression of an *Intentionall* Odour in the *Medium*.

Did not *Auerrhoes* remember that ruled Axiom, *Nihil est in intellectu quod non prius fuerit in Sensu*? That there is nothing in the mind which is not first in the Sense? And to what purpose should any thing that is in the vnderstanding bee remitted or returned vnto the Sense, seeing things are therefore receiued into the Sense, that they might attaine vnto the vnderstanding. And whereas *Auerrhoes* saith, that there would be penetration of bodies, if the odorable Obiect did really alter the *Medium*, I answer the consequence is not good: for the ayre being a most liquid Element, doth easily yield to any body. Adde beside, that a fumid exhalation being mingled with the ayre, may be caried and recaried with it hither and thither. After this manner also, the opinion of *Philoponus* and *Iandunus*, may bee refuted, who doe affirme that the Odour may really together with the exhalation be caried a good space through the *Medium*, marry the rest of the *Medium* which attaineth vnto the organ of Sense, is altered onely intentionally by the Odour, for a reall Beeing doth alwayes worke really, and that which is *Intentionall* dependeth vpon our vnderstanding. But if some part of the *Medium* were really changed, and other parts intentionally, What is the reason why in remote distances a great tract of the *Medium* is really affected; and in little distances (as when we moue the obiect to the Noses) but a little.

Philoponus & Iandunus refuted.

Aegidius was of opinion that the odour was really produced in the *Medium* as is the Sound, which sayth *Placentinus* is vterly false, for not so much as colour, which is simply and immediatly made out of the mixtion of the first qualities, can possibly after any manner bee receiued in the ayre. How then shall odour which is a second quality bee generated in the ayre. Furthermore *second qualities cannot mutually worke one vpon another*: for one white cannot produce another white, no more can one odour which expireth or breatheth out of a body beget another odour in the *Medium*.

As also Aegidius.

And for this cause wee also must disclaime *Ammonius* and *Boetius*, who say that an odour may passe out of one subiect into another; for although it proceede together with the exhalation out of the bodies into the ayre, yet it doth not change his subiect nor flit into another. But the ayre being made vapourous sustaineth the exhalation together with the odour, conserueth it and is a vehiclle vnto it: yet when the vapour is dissipated the odour vanisheth together, therewith, which would not happen if it were fit to flit or moue out of one subiect into another.

With Ammonius & Boetius.

Wee therefore with *Anicem* doe resolute that the *Medium* is really changed: for that the odour doth really yssue out of the mixed body wee haue proued before: from whence it followeth necessarily that some part of the *Medium*, to wit, that vpon which the odoriferous exhalation doth immediatly worke is really affected. Againe, Odours doe really attaine euen vnto the braine, and therefore there is no question but that the *Medium* is really affected. Those therefore that say it is affected intentionally, as also those that confesse some part of it to be affected really, but other parts intentionally, haue sitten downe beside the Question.

Anicem redeemed.

The Medium is really affected.

For they really affect the braine.

Confirmed by a strange instance.

Science is from the Senses.

Objection.

Solution.

But although the odour proceede really out of the subiect and reach really vnto the braine, yet no man must conceiue that the odour is diffused through the whole *Medium* from the object euen vnto the organ, but it is waisted vpon the wings of the wind or transported by the motion of the ayre. That an odour attayneth really vnto the braine may bee proued; because such odours do sometimes helpe and sometime hurt. The detriment seemeth not to proceed from the odour but from the quality of the subiect which accompanieth the odour, that is, the exhalation. For the odour being a quality cannot haue in it that hurtfull quality vnlesse you will graunt that a quality can bee in a quality. Neither doeth the quality onely of an exhalation affect the braine, but sometimes some seedes of the very substance of bodies that are of subtile partes are transported in the exhalation, which settling in the braine bring forth fearefull accidents and strange effects, as it did in him who smelling oft vpon Basill had a Scorpion bred in his braine. It is therefore necessary we should beleue that the odour is really *perceined* by the organ. For confirmation whereof wee may also adde this argument, That all knowledge or science hath his originall from the Senses. Now science is of a reall not of an intentionall Being. How then shall science which hath a reall subiect take his beginning from the Senses if they receiue nothing but that which is Intentionall?

It is therefore manifest that the Senses doe not *perceine* their objects intentionally but really; and by consequent that the *Medium* is also really affected.

But it may bee objected, if the odour be really imprinted in the Organ, then there is no neede of an externall *Medium*, and beside, that *axiome* will bee false, That the object vpon the Sense doth make Sensation.

Wee grant indeede that there is no neede of a *Medium* which should be betwixt the reall odour and organ, but the vse of the *Medium* is of the conseruation, preparation and transportation of the odour.

QUEST. LIIII.

What is the true and principall Organ of smelling, where Aristotle is confuted.

Alexander hath often testified that in euery perfect organ, there may be obserued diuers kinds of parts. Of these parts some bee principall, to which the action is primarily to be attributed. Some againe be such which make the action more excellent, and others doe conserue the action.

Now that the Nose is the Organ of Smelling no man will deny, but because diuers parts doe concurre vnto the constitutiō of the Nose, to wit, bones, gystles, muscles, small nerues, membranes, & the mammillary processes; it is therefore controuerted betwixt the Physitians & Peripatericks, to which of these parts, as to the chiefe cause, the actiō is to be ascribed.

A difference betweene the Peripatericks and Physitians

Aristotle in his second booke de *Anima*, and in his booke de *sensu & sensibili* doth affirme that the externall Nose which is conspicuous in the face, is the chiefe Organ of Smelling; wherein he conceiueth there is a couer like a value which is neuer opened, but by inspiration, whence it is that wee haue no Sense or perception of odours but when we inspire.

Galen demonstration

Galen in his booke de *odocratus Organo* doth in the third and fourth whole chapters vehemently inueighe against *Aristotle* where hee teacheth that indeede the externall Nose doth something conferre vnto this sense of smelling, but the chiefe Organ thereof is within the skull; And for the confirmation of this conceite, he vseth an elegant and inuincible demonstration from the enumeration of the seuerall parts of the Nose. For, neither saith he can the bones, nor the gystles, nor the membrane, nor the nerue dilated through the membrane be the true organ of the Smell, and therefore no externall part of the Nose can bee. As for the bones and gystles they are so farre from hauing the Sense of smelling that they haue not so much as the faculty of Touching allotted vnto them: they therefore are farre vnfit for the performance of this function. Again, euery *organon* or organ ought to communicate in nature & conformation with the sensible thing; that so the organ might be more easily altered by it. But nothing is agreeable to the nature of Odours, but that which is vaporous: betwixt the nature thereof and that of bones & gystles, there is very great distance.

As for the membrane which inuesteth the Nose; it is indeed endowed with most exquisite Sense of Touching, yet it is too crasse and thicke, for the reception of such subtile objects as odours are. And beside, this membrane or coate is also common to the tongue and

and the Palate and mouth, but in those parts it hath no Sense of odours. Again if this membrane were the true instrument of Smelling, then it should continually perceiue the appulsion or beating of the odours; but there is no preception of odours, except when we do inspire; for though you fill the Nose full with Muske or Ambergreese or other odoriferous bodyes; yea though you should annoynt the whole membrane with sweete oyles, yet you shall haue no perception of odours except you draw in the Ayre by inspiration; wherefore we conclude that the principall Organ of Smelling is not placed in the bone or grystle or membrane, or any other part of the externall Nose.

The membrane is not the instrument of Smelling.

As concerning that couer or value (whereof this great Philosopher dreamed) which is open when wee draw in our breath, and shutteth when wee hold our breath, *Galen* doth in no sort acknowledge it in the aboue named places, neither will any well skilled in Anatomy admit of it. But yet put the case that there be such a value in the interiour part of the nostrils, and that it doth sometimes open it selfe to make a passage for the ayre and vapors which we draw in, and that it shuts againe when wee cease our inspiration, then surely the motion of this couer must either be animall or naturall, or violent. That it is Animall or voluntary, no man will say, because there is no neede of such a value vnto animall motion. And beside, all animall motion is at the command and in the gouernment of the soule, and obedient vnto our will and appetite, but this value is neuer opened but when we draw in the Ayre. Moreouer, the immediate instrument of voluntary motion is a muscle, but there are no muscles to be found in the depth of the cavity of the nostrils.

That there is no value Reason.

Neither is this motion Naturall as is the motion of the values of the heart. For the heart is perpetually mooued, and that motion performed by it owne instinct and not by our will.

If you thinke it bee violent because it is forced by the inspired Ayre, then giue eare vnto *Galen*'s obseruation ouerthrowing this conceite. For, saith he, if you shall force either much ayre or any liquour into the nose through a pipe and hold your breath, why is not the value opened if there be any such extent, and why should there not be a perception of those odours in the Nose? If the Peripatetickes shall insist, and retort our owne argument, and fight against vs with our owne weapons, and say, if the Mammillary processes bee the principall Organ of Smelling, why doth not sweete Ayre being driuen with force and violence through a pipe moue the Sense?

Objection, Solution.

Galen answereth, that the aire being blowne and forced through a pipe, if wee hold our breath doth neuer reach vnto the Braine, because all partes of the Braine are full of Ayre when the Braine is contracted by expiration; but when the Braine is dilated by his inbred power all the spaces are enlarged, and so for the auoiding of vacuitie are filled with inspired aire. The aire therefore cannot attaine vnto the processes and Ventricles of the Braine but onely by inspiration, because except the Organs be dilated, how shall the aire passe through those pores which bee already full of ayre? Now if aire cannot be brought but by Inspiration vnto the Mammillary processes, then surely cannot the species or kindes of odours: for as the character and quality of the sound cannot bee carried vnto the Organ of hearing but by the meanes of the intermediate ayre, no more can the qualitie of odours attaine vnto the organ of Smelling. Let *Aristotle* therefore patronize his owne opinion himselfe.

Wee with *Galen* and the Physitians do resolute that the principall organ of the smell is seated within the Scull and a portion of the Braine, namely, those processes and two bunching productions which are like to the Nipples of a womans pap, and doth reside or rest vpon the highest bone of the Nosethrils.

The true Organ of smelling.

And this hath *Hippocrates* bewrayed in his Booke *περί ἀρτηρίας*, where he saith, That the Braine doth smell the odour of dry things together with the aire, drawing the same thorough two cartilagineous or gristly bodies. And to him doth *Galen* beare witnesse in his booke *De Odoratus Organo*, in his eight booke *de vsu partium*, and in his first booke *De Sympt. Causis*. And lastly sound reasons doe also euince this our opinion. First, that part is to bee accounted the principall which hath a peculiar substance, figure and composition. Witnesse *Galen* in his sixt booke *de Placitis Hippocratis & Platonis*. But the processes amongst all the parts of the nose haue a peculiar nature, figure and composition, which you cannot finde in any of the other. But the Bones, Grystles and Membranes are euery where alike. Wherefore the principall cause of this action of Smelling is to be ascribed to the Mammillary processes.

The Mammillary processes. Authoritie.

Reasons proving this first.

Again, there is no part in the nose which can be altered by odors, but these processes being

Reason being

being full of spirits doe with facility receiue the species of odours, & because they are neere of a kin to the Nerues, they haue a kinde of Notion of that qualitie which they perceiue.

Auerroes
disproouing
Galen.
First reason

Auerroes being a bitter enemy to Physitians in the defence of *Aristotle* endeauoureth to ouerthrow this opinion of *Galen* but with very easie Engines. If (saith he) the Mammillary processes were the organs of Smelling, then the odour of those things which are bruised in the mouth would be smelt when the Nofethrils were obstructed and shut, because there is a manifest passage for the aire open from the mouth and palate vnto those processes.

Second.

Moreouer, the odour of those meates which are contained in the Stomack would be perceived, for there do certaine vapours expire there-from vnto the Braine, during the whole time of the concoction. And lastly, such creatures as wanted these processes would also want the sense of Smelling. But I thinke we may fully satisfie these obiections on this manner. First, although there be a way open out of the mouth into these processes, yet notwithstanding there is not any perception when the nofethrils are shut, because the odours should first be offered vnto the Nofethrils and there bee prepared; without the nofethrils therefore there can be no perception of odours, and yet it doth not follow that the Nofethrils therefore are the principall organ of this Sense. Euen as without the watery humour no vision can be made, and yet no man will say that it is the principall Organ of Sight.

Third.
Galen answer.

But besides this, there is another reason why when our noses bee shut, those things which are chewed in the mouth and are contained in the stomacke are not smelt, to wit, because the odour being as it were drowned and strangled with the excessiue humiditie of the mouth cannot make shew of it selfe, nor imprint his nature species and forme in the Sense of Smelling. For odour is (as *Aristotle* himselfe in his second Booke *de anima* affirmeth) of a dry thing, as a Sapor of a moyst thing. So those which are troubled with the *Coryza* or a distillation out of the head into the nose which wee call the *pose*, doe not perceive the formes of odours.

Why we doe
not smell that
which is in
our mouth and
Stomacke.

Moreouer, that vapour which is brought from the Stomacke vnto the Braine is not perceived by the smell: because such vapours are too familiar and too well acquainted with the Braine, so that no alteration can be made by them. In like manner those which vse to eate much garlicke haue no sense of their owne stinking breath.

As for *Auerroes* his last obiection, that many creatures wanting these processes, yet do perceive the fauour of odours, is not any whit repugnant vnto *Galen*. For he speaketh onely of perfect creatures, and not of imperfect, which as they can stand without bones and liue without Lungs, so there is no reason but they may respire and breathe without nofethrils or these Mammillary processes.

The conclusion.

Wee conclude therefore that those two swelling mammillary processes are by good right accounted the principall organ of smelling, yet notwithstanding wee affirme that there can be no perception of odours without the helpe of the nofethrils and the spongy bone; And thus much of the Sense of Smelling. Now we proceede vnto the Taste.

QUEST. LV.

Whether Taste be the chiefe action of the Tongue.

ALbe it be commonly knowne that to Taste is an action of the Tongue, yet it shall not be amisse to make this truth somewhat more manifest, for the Tongue is ordained for many vses. First to articulate the voyce. Secondly, for mastication or chewing, because it containeth the meate within the mouth, and rowl-eth it vnder the mill-stones of the Teeth. Thirdly, for the Taste and dignotion or perception of saviours. The question therefore shall be, which of all these is the principall action for which Nature ordained this instrument, because we assigne vnto one part but one principall action. That therefore is called the principall action for which the Tongue was primarily instituted by Nature. And that Action is primary which is most necessary, the rule of Nature being first of all to provide for the necessity of the creature. The action therefore which is most necessary is also the principall action.

The diuers
actions of the
tongue.

Which action
is principall.

Speech is not
the principall
action of the
tongue.

I know well what great vse wee haue of speech, and how miserable the life of a dumbe manis, yet because other actions are more necessary, therefore wee cannot beleue that speech was the principall end for which Nature ordayned this Organ. Now that other functions are more necessary then speech we neede not to doubt, because those are absolutely necessary

necessary to life, this onely to better life. That the other functions are absolutely necessary, for the conseruation of life is hence manifest, because brute beasts cannot liue without them as they doe without speech.

But amongst those other functions, which is the most necessary, is harder to discern, yet to say truly mastication is not an action of the Tongue, and therefore wee will not stand in this place to dispute the necessity of it. For it is an instrument of mastication but by accident, as it rowleth the meate vnder the Teeth that chew it. But a principall action belongeth not to a part by accident, but by and of it selfe. Againe, it were absurd, to say that the principall action of so noble a member, did but helpe the Teeth to chaw the meate. Adde hereto that mastication or chewing it not so necessary to life as Tasting is, for Infants doe swallow their meate without chewing, and so doe most Fishes, as *Aristotle* remembreth in the eleuenth chapter of his booke *de partibus Animalium*, but without Taste the creature cannot liue. Not that if their Taste be lost, they must presently perish, (for it was a custome among the Ancients for blasphemie to cut out mens Tongues and yet they died not) but because all creatures taking delight in some one kinde of food or other, when the sense of pleasure is taken away, they abstaine from those meates, or take but little and so pine away to death. And this is the opinion of other men concerning the necessitie of the Taste. I, saith *Placentinus*, doe rather thinke it therefore necessary, because when it is lost the creature taketh all meates indifferently, and by that meanes is often extinguished by poyson in steede of nourishment. Seeing therefore that perpetuall nutrition is absolutely necessary vnto life, therefore Nature ordained this Sense, to take the assay, which was fit should be very exquisite, because the Lord it serueth, which is Nutrition, was the principall act for which the creature was ordained.

Wee conclude therefore that of all the actions of the Tongue the Taste is the chiefe, and that the rest are but seruants and attendants there-vnto, especially Mastication.

Not Mastication.
Reasons why

The necessity of the Taste.
An old kind of punishment of Blasphemy

The reason of the necessitie of the taste.

QUEST. LVI.

Whether the Taste differ from the Touch.

THE Taste is one of the fine externall Senses, whereby wee discern the differences of saviours. This Sense hath great affinity with the Sense of Touching, in so much that some haue made no distinction betweene them, but haue placed the Taste vnder the Touch, as the species vnder the Genus, for which they haue not onely *Aristotles* authority, but very strong reason. The authorities they produce are these. *Aristotle* in the second Chapter of his Booke *de Sensu et sensibili* saith, that the Taste is a kinde of Touching. Againe, in many places he affirmeth that Taste hath a kinde of Touching, as in the 4. chapter of the Booke before named. In the 64 Text of his third booke *de anima*. In the 17 chap. of his 2 Booke *de partibus animalium* and in infinite other places. But these authorities seeme not to be of any great consequence, because the same *Aristotle* hath oftentimes affirmed that all sense is a kinde of Touching; from whence it should as well follow that there is but one Sense, that is, the Touch, then which nothing can be more absurd. Wee must not therefore conclude that the Taste and the Touch are all one, because *Aristotle* saith, that the Taste is a kinde of Touch.

What Taste is and how neere a kin to touch

Aristotle. authorities.

It seemeth to mee notwithstanding that there is something in it, why particularly in treating in diuers places concerning the Taste, hee calleth it rather a Touch, then the other Senses, especially in his proper Treatise of this Sense; whereas hee giueth no such attribute to any other of the Senses. For in his chapter *de visu* hee doth not say that Seeing is a kinde of Touch, nor shall you finde in the Chapters of Hearing and of Smelling any such matter. Further, this opinion is confirmed by *Aristotles* argument, because hee ascribeth the same object to both these Senses; for in the very beginning of his Chapter *de Gustu*, that which is Gustable or fit to be Tasted, is also Tangible and fit to be Touched. And comparing the Taste with the Touch, he saith that there is the very same reason and nature of them both. Yea, that they differ nothing one from another. And in the 28. Text of his second booke *de Anima*, he speaking of set purpose auoucheth the very same, for he sayth not onely that which is Gustable is also Tangible, but also that the Touch is the Sense of Aliment. And about the end of the same text expressly naming the object of Taste, he saith, that a Savour is one of those objects which are perceived by Touching. And in the 63. text of the

Called into question.

And expounded.

same

same booke more playnly thus; *Wherefore the Taste it selfe is a kinde of Touching, for it is the Sense of alimens, now alimens is a body which is perceined by the Touch.*

If therefore Tasting and Touching haue one and the same obiekt, surely they are one and the same Sense. As from the plurality and diuersity of obieks, the plurality and diuersity of the Senses is gathered, so from an vnity and Identity of the obiekt it must needes be there should follow also an vnity and Identity of the Sense.

They adde also an argument gathered out of *Aristotle* in the beginning of his Chapter *de Gustu*, on this manner. *Taste and Touching doe equally perceine that which is moyst, yea moysture though it be insipide (some say) may be discerned by the Taste.* Seeing therefore the obiekt of the Touch may be perceined by the Taste, and the obiekt of the Taste, reciprocally by the Touch, they must be esteemed distinct Senses.

Finally, they adde out of *Aristotle* that in the 23. text of his second booke *De anima*, and in the 68. text of the third booke he saith, that the Touch onely is necessary for the creature. And againe, in the fourth chapter of his booke *de sensu & sensili*, as also in the last chapter saue one of the third booke *de anima* hee saith, that a creature cannot bee without the Taste; wherefore say they, *Aristotle* thought that the Taste and the Touch were both one, otherwise there should be a repugnancie betwixt these two places.

All these particular instances out of *Aristotle* doe at the first blush seeme to prooue that he was of their mind. But if we looke somewhat more narrowly into them we shall finde that there can be no such thing gathered from *Aristotle* by good and lawfull consequence.

Answer to
Aristotle's au-
thorities.

To the first
instance.

For first whereas he saith that the Taste is a kinde of Touch, it is nothing else but to demonstrate the affinity betwixt these two Senses; for if he had meant that the Taste and the Touch did not differ in *specie*, hee would neuer haue said that *Gustus* is *Tactus* quidam, but simply and plainly *Gustus* is *Tactus*, hee should not haue said that Taste is a kinde of Touch, but that Taste is a Touch. Neither are we to wonder why *Aristotle* speaks in this manner rather of this Sense then of any other. Is it not because none of the other Senses haue any such acquaintance or familiarity with the Touch as the Taste hath?

The affinity
betwixt the
Taste and the
Touch.

Consider first that the Taste as also the Touch is made without a *Medium*, so are not the rest of the Senses. The reason is, because as well in the Taste as in the Touch the obiekt must touch the Organ, so that their extreme parts are contiguous one which another. Hence it is that the Gustable obiekt being about that which Tasteth, maketh Gustation, whereas in other Senses there is no comprehension of the obiekt by the Organ sauing by the interposition or mediation of a *Medium* or middle body.

Answer to the
second in-
stance.

Finally the obiekt of the Taste is more endowed with tactile qualities then the obieks of the rest of the Senses as being more corporeall, materiall, earthy, and to speake in a word, correspondent or answerable to the Tactile obiekt, so that *Aristotle* might well say, that that which was Gustable was a kinde of Tangible. Seeing therefore this Sense of Tasting hath so many more conditions concurring with the Touch then the other Senses, it was not without cause that *Aristotle* so often compared the Taste and the Touch, and in a manner of speech confounded them, but was more sparing in the collation of the Touch with the other Senses. And hence wee may shape an answer to the second authority, for he doth not say simply *Gustabile est Tangibile*, but *Gustabile est quoddam Tangibile*, adding a conditionall particle whereby he would intimate that there was a great vicinity or neighborhood betwixt these two kinds of obieks, yet notwithstanding that they did so differ, that they did not fall vnder one and the same Sense.

To the third.

First Answer

The third argument is weighty and difficult; for without any condition or limitation he saith, that a Sapor is perceined by the Touch, and that the Touch is the sense of Aliment; notwithstanding wee answer that *Aristotle* doth not make a Sapor as it is a qualitie properly Gustable, but as it is in a gustable body. For this body is indeede perceined by the Touch, not as it is Gustable, but in respect that beside the Sapor it hath also many Tangible or Tactile qualities.

The last

Add moreover, that the word *χυμὸς* which *Aristotle* vseth, doth not onely signify a Sapor but also a iuice and humor indued with a Sapor, whence the Physitians call those meates *ευχύμους*, not which are well-tasted but which yeelde a profitable and Alimentarie blood vnto the bodie: againe on the contrary they call those meates *κακοχύμους* which yeelde a bad and vicious iuice, and that disease is called *κακοχύμια*, when the body aboundeth with euill and vicious nourishment. Wee are therefore to beleue that *Aristotle* is thus to bee vnderstood, because so oftentimes he testifies that Sapor hath his residence or being in humidity, or that which is humid and moyst.

I might also say that *Aristotle* speaketh in that place of that Savour which nourisheth. Now a Savour as it is a Gustable quality doth not nourish, because that which is incorporeall cannot be turned into a body, but that which nourisheth must of necessity be converted into the body that is nourished. It is therefore no question but that when *Aristotle* spake of a Savor hee meant it *de corpore Sapido*, that is, of a body which was not without Savors or Tastes. And indeede a Sapid body may nourish. So saith *Avicen*, that which hath a good Taste doth also nourish, not that the Savor or Taste doth nourish, but the substance wherein the Sapor doth consist.

Third answer.

Avicen

On this manner also is *Aristotle* to be expounded, where hee saith, that the Touch is the Sense of aliment, for he doth not meane that it falleth vnder the Touch and vnder the Taste after the same manner and in the same respect: but vnder the Touch in regarde of the Tactile qualities, vnder the Taste in regard of the Sapor. It is as much therefore as if hee said, *Because the Aliment as it is a body cannot be found without Tactile qualities, the Touch indeede perceiveth these qualities, but it perceiveth not the Sapor as it is a Sapor.* And therefore in the 63 Text of his third Booke *de Anima*, after hee hath sayd that the Touch is the Sense of Aliment hee explaineth himselfe after this manner, *But the aliment is a Bodie which is perceived by the Touch.*

To the fourth

Seeing therefore the Aliment is a bodie, it must have both Tactile and gustile qualities, and therefore may be truly called the object both of the Taste and of the Touch, yet is it the object of neither Sense as it is an Aliment, but of the touch as it is moist and dry, hard and soft: of the Taste, as it is sweete, bitter, salt and the like.

As for the reason which they alledge out of *Aristotle*, I hold it to be of no weight, because *Aristotle* had no such intention; yet we may grant that moisture is perceived by the Taste not as it is moisture, but as it is sapid: and that insapide moisture or moisture without Taste may be discerned by the Sense of Tasting, that I utterly deny.

To the fifth

Concerning the necessity, that which they vrge is meerely friuolous, for *Aristotle* supponeth that the Touch is simply necessary so that the creature without it cannot subsist: but the Taste is necessary in respect of the Touch, because it is a kinde of Touching: yet we doe not denie but that the Taste also is necessary *secundum quid*, as we say in the Schooles, that is, not of it selfe, but because the creature wanteth nourishment. It doth not therefore follow that either the Taste and the Touch should be both one, or else that an imputation should be cast vpon *Aristotle* for contradicting himselfe.

To the sixth

It may be also objected, that because both the Taste and the Touch are together in one and the same Tongue, that therefore they shall be one and the same Sense. But the consequence is not good, for there is no organ of Sense, which beside this proper Facultie of Sensation is not also furnished with the Sense of Touching. But because the Sense of Tasting is not alwayes found where Touching is, and where it is found there is no other Faculty of Sensation: I conclude that not onely all the other Senses but the Taste also is a distinct and different Sense from the Touch.

Objections

Solution

QUEST. LVII.

Of the object of Tasting.

THe object of the Taste saith *Aristotle* in the fourth Chapter of his Booke *de Sensu & sensibili*, is not onely more evident and manifest vnto vs then the Odours are, but also then other Sensible Objects. The reason wee may giue out of the same place of *Aristotle*, because the Taste is a kinde of Touching, which Sense in a man is more perfect then all the rest:

The object of Taste is more evident then of other senses and why.

Now the Object of the Taste is that which is *Gustabile* or *Gustile*, which word signifieth two things, to wit, Savour or qualitie and affection seated in a sapide body, and the body it selfe wherein the Sapor is. But the Sapor is the proper and adequated or proportionable object of the Taste, and therefore *Aristotle* appropriateth the word *Gustabile* to the Sapor. As (sayth he) *visibile est color, sic Gustabile est sapor*, as that which is visible is a Colour, so that which is Gustable is a Sapor: as if he should say, that a Gustable body is no way Gustile or to be Tasted, but onely in respect of his Sapor. Yea hee oftentimes puts *Gustabile* for *Sapor*, the reason is because a Sapor hath no existence of it selfe, neyther can it moue the Sense but hath all his being and essence in the mixt body. That ther-

2. significations of Gustabile.

fore

fore which he calleth *Gustabile* is a mixt body, which in respect of that quality which is called a Savour is Gustile or may bee Tasted. Not that a Savour doeth by it selfe mooue the Sense, but because it cannot subsist without the mixt body, for considered euen without the mixt body it may be said to be the object of Taste, because it is it alone in the mixt body which mooueth the Sense.

QUEST. LVIII.

Of the matter of Sapours.

What a savour
is.
2. kinds of
first qualities.

Savour is a quality arising out of the first qualities, which alone by it selfe is able to mooue the Taste. Now the first qualities are of two sorts: some Actiue, as heate and cold; others Passiue, as moysture and drought. Out of the Actiue qualities the Savour hath his Efficient cause, to wit, heate; out of the Passiue his Materiall cause, to wit, Moysture. But least any man should wonder why we make moysture which is nothing else but an incorporeall quality to bee the matter of Sapours: We answer, that we vnderstand humidity not in the abstract but in the concrete. So that haply it were more proper to say *humidum* then *humiditas*, for to say truth, a Savour is not made onely of humidity, but of humidity ioyned with siccity, yet so that the humidity is predominant.

Sapours are
not made of
simple humidity.

Wherefore *Aristotle* sayth that a Savour dwelleth in that which is moist, as an odour doth in that which is dry; yet he doth not name humidity alone, nor simple siccity, but both conioyned, and therefore he rather expresseth himselfe by *humidum* and *Siccum* then by *humiditas* and *siccitas*: so that in the one the moysture preuaileth ouer siccity, in the other the siccity ouer moysture. For thus much doth *Aristotle* intimate in his Booke *de sensu & sensibili*, where he saith that the vniuersall nature of Savour is, that it is a passion of the Sense of Tasting made by that which is earthy, dry, in that which is moyst. Wherefore humidity being predominant in an earthy siccity is properly the matter of Sapors.

1. Obiection

It may be objected, if in Sapours the humidity must preuaile ouer the siccity, then those bodies wherein the siccity preuailes ouer the humidity should bee insipide and without Taste. Now there are many in which the siccity is predominant, as Ashes, Pepper, Ginger and such like, which notwithstanding haue a very sharpe and quicke Taste. Adde moreouer that if that were true, then Sapours should not properly belong vnto Aliments; for *Aristotle* sayeth in the 28. Text of his third Booke *de anima*, that hunger is an appetite of that which is hot and dry. An Aliment therefore is not moyst but hotte and dry, because it appealeth hunger. Seeing therefore all men confesse that Sapours doe properly belong to Aliments, it should seeme also that Sapors haue their residence not in moysture but in siccity.

2. Obiection.

We answer, that an Actiue Savour, that is, such a Savour which is instantly fitte to mooue the Taste must necessarily bee in moysture. That which they obiekt of Pepper, Ashes and such like, wee answer on this manner. Wee grant that of themselues they are insipide and haue no Savour but that which is potentiall, for they doe not Taste till they be chewed, and that is by accident: when as that humour which perpetually remaineth in the mouth and the tongue, prouoketh or produceth their potentiall vertue into Act, but because siccity is in them predominant, therefore they yeeld a sharpe and quicke Taste.

Solution 2.
2. kinds of
Aliments.

That which they adde concerning Aliment is easily answered, for there are two kinds of Aliments; one which satisfieth hunger, another which satisfieth thirst. That which satisfieth thirst is exceeding moyst, and in respect of it that which satisfieth hunger may bee called dry, although it doe not follow that it should simply be dry, yea it is necessary that it should haue so much moysture as the Sense of Tasting doth require otherwise it could not satisfie hunger.

Finally, whatsoever mooueth the Taste must of necessitie haue an inward moysture wherein it is steeped, although it hath no outward, the reason is, that it may melt and diffuse it selfe through the organ of the Sense, for those things that are hard and cannot bee dissolued cannot mooue the Sense of Tasting; as wee may conceiue by a rough and torried tongue such as we see is chapped and blacke in violent Feuers, which cannot make any certaine estimation of the differences of Sapors.

QUEST. LIX.
Of the efficient cause of Sapors.

F the passive qualities therefore moysture preuailing ouer Siccity is the matter of Sapors. Of the active qualities they haue heate for their efficient cause. For as the simple and pure Elements are of themselves without sapor or odor, so also in the mixt body no such thing would result out of them if euery Element should reserve his owne quality to himself; and therefore there is neede of heate to draw out the Sapors out of the concoction of the humidity and Siccity, by which concoction these two are fitly mixed one with the other, neither is it reason that any man should substitute cold to this office, for daily experience teacheth vs that fruites when they are frozen, as Apples, doe vtterly loose their taste; yea although they be thawed and resume their former heate their tastes do not returne. So that cold is so farre from being the efficient cause of Taste, that rather it doth vtterly destroy it. Adde hereto that no fruite attaineth his native Tast till it grow ripe, now this ripening is made by heate. It remaineth therefore that heate in as much as it concocteth humidity, and accomplisheth perfect mixtion, is the true and onely efficient cause of Sapors.

Heate is the efficient cause of Sapor.

How that is. Cold cannot be.

Why frozen fruites loose their Taste?

QUEST. LX.

Of the number and order of Sapors.

Aristotle in the 4. chapter of his booke *de sensu & sensili* going about to recite the diuers kinds of Tasts compareth them with colours, not because there is any great affinity betwixt them, but because there is in it as many of the one kinde as of the other, and he concludeth them both vnder the number of seuen. Some say there are eight kinds of Sapors, and Pliny in the 21. chapter of his 15. booke, reckons vp thirteen. We with Aristotle will rather reduce them vnto the number of seuen, because, as there may be (and indeed there are) infinite varieties of mixtion, so we might draw out of them infinite differences of Sapor, if it were possible accurately to nuber them; for nothing is so sure as that the differences of Sapors doe arise from the multiplicity of mixtion; for example, out of that wherein heate and moysture are abundant, a sweet Sapor; out of that that is hote and dry, a bitter and salt Sapor, and so in the rest, as this or that quality hath greater or lesse rule in the mixt body, yet alwayes moysture must haue the first place.

How many kinds of Sapor.

As many as of mixtures.

An instance of this we haue in a place of Galen, in the sixth, seventh and eight chapters of his fourth booke *de simplicium medicamentorum facultatibus*. The fruites of trees (saith he) that appeare to vs to be sweet when they be ripe, are soure when they are yong, & dry of consistence, but in processe of time they become moyst, and their sowrnes turnes into sharpenesse, which sharpenesse they loose by degrees as they grow ripe and at length become sweet.

An elegant place of Galen, concerning Sapor.

Among these Sapors; Salt and Bitter are contrary to sweete, because being vnder the same kinde there is the greatest distance betwixt them, Aristotle hauing a respect to white and blacke calleth them *privatiues*: and that not without good cause, for although being vnder the same kinde they differ most one from another, yet they cannot be truly said to be contraries: for sweetnesse is generated in a subiect that is fulfilled with heate and moysture, but salt and bitter are in a subiect which is hot yet very dry, and therefore the sweet Sapor nourisheth more then the rest, yea we thinke that all other Sapors doe nourish onely by reason of their sweetnesse which lurketh in the secret bowels of the sapide body, although by the Taste it cannot be so manifestly perceived. For all nourishment must be conuerted into bloode that so it may become a fit nourishment vnto the parts, but laudable and good blood is hot & moyst and sweet to Taste to. That Sapor therefore which hath the greatest Analogy and affinity with bloode is fittest to nourish, and such is the sweet Taste.

Salt and bitter are contrary to sweet.

Other Sapours which haue no sweetnesse at all in them are altogether vnfit for nourishment.

There are some which thinke that sweet and bitter are not the extreame Sapors; grounding themselves vpon Plato in *Timaeo*, because (say they) those Sapors are to be accounted extreames which come neere vnto the first qualities. But neyther sweete nor bitter are such, but *styptrick* or *binding* and *keene*, for the keene taste or byting, such as is in Pepper.

per resulteth out of a high degree of heate. The other which bindeth and contracteth the Tongue ariseth from extreme cold.

Againe, those objects that are extreame doe hurt and offend the instrument; now sweet doth not hurt but refresheth it, yea it conserveth the temper thereof by an acceptable pleasure and delight. Another Reason may be, why sweet is not an extreme Taste, because from *sowre* to *keene* the passage is by *sweet*. So that whatsoeuer is *keene* or biting when it is ripe, and *sowre* when it is greene, will haue a kinde of sweetnesse in it before it come to his perfection. Now in qualities the transition is by the mediate or meane qualities, not by the extreame. It is therefore to be concluded, that not *sweete* and *bitter* but *sowre* and *keene* are the extreame Sapors.

That sweet
and bitter are
not extreame
Sapors.
Arguments.
Refuted.

But although we must needs confesse that these Arguments haue some life and strength in them, yet we presume that *Aristotles* opinion may well be maintained. It is true indeed, that if you consider Sapors according to their originall, that is, as they result out of the first qualities, our aduersaries haue concluded well. But if you regard Sapors, without respect vnto their originall and simply as they are Sapors, that is, naked qualities which moue the Taste, then our Aduersaries are in the wrong.

Plato expounded.

Aristotle defended.

It may well be, that *Plato* vnderstood the matter on this manner, because he doth especially attend to the temper of the body in which the Sapors are, but this is not the proper contemplation of Sapors. *Aristotle* who of purpose disputed concerning Sapors vnderstood them according to their proper Nature, to wit, as they moue the Taste: for a sweet and a bitter Sapor do more and affect the Sense after the most contrary manner. So colours are not to be considered as they are nearer or further off, to or from the first qualities, but as they affect the Sight, and in this respect white and blacke are called extreame and contrary colours, because they affect the sight after a most contrary manner, for *white* dissipateth the Sight, *blacke* congregateth and vnitheth it.

Why Sapors
are called ex-
treame.

Answer to the
second reason.

To the third.

Whereas they say that the keene and Stipticke Sapos do hurt the organ, they are deceived if they meane it in respect that they are Sapors; for the truth is, that the Offence commeth from the first qualities, to which those Tastes are too neere Neighbours. And this is the reason also why the passage is from *sowre* to *keene* by *sweet*, because those qualities are so changed in the mixt body, that after *sowre* doth succeed *sweet*, and after *sweet* *keene* or *hot*. Their consequence would follow, if the *sowre* Taste should engender sweet, and sweet should engender that that is keene and hot, but there is no such matter: for who did euer say that the second qualities did arise one out of another? For they proceed not so much from their first qualities as from the condition of the matter. We conclude therefore, that because the sweet and bitter Tastes as they are Tastes or Sapors, do after a most contrary manner affect the Sense of Tasting, that therefore these are the extreame Sapors.

Second qual-
ities arise not
one from ano-
ther.

How many
intermediate
Sapours.

Hauiug thus resolued which Sapors are extreame, let vs now a little consider what are the intermediate, which with *Aristotle* we reckon six, *Fat*, *Salt*, *Keene*, *Sowre*, *Sharpe* and *Tare*, which in Latine are called *Pinguis*, *Salsus*, *Acris*, *Acerbus*, *Acutus*, and *Acidus*.

Why they are
infinite.

I list not to oppose *Pliny* or any man else that hath bene pleased to make more differences of Sapors, these are those that are most manifest, and therefore *Aristotle* contented himselfe with them, the rest being very obscure or at least not knowne to such as this our labour shall concerne. Thus much onely we will admonish you of, that all the variety of Tastes beside those we haue accounted, do arise from the innumerable variety of mixtions, from the different constitutions of the organ, as also from some secret and vknown instincts which do reside in particular bodyes, whereof to say truth we can giue no reason at all.

All Sapours
cannot be
defined.

Wherefore because the Sapors themselves are infinite, their proportion very diuers, and their causes so transcendent, it is not possible to make any definition or description of them to any purpose. Who can deny but that some creatures, yea some men doe vehemently desire bitter things and abhorre that which is sweet: are bitter things therefore sweet to the one and sweet things bitter to the other? You will say no, because the difference ariseth from the diuersity of his Temperament that Tastes it. I confesse it, but seeing there are almost so many diuers Temperaments as there are *indiuiduals* or particular creatures in the world, I would aske the question whether it be possible that so many different kinds of Sapors, may be reckoned or deduced from them? By no means: no more is it possible to define them.

A definition
of sweet and
bitter.

Wherefore if you looke into the vulgar descriptions of Sapors you shall finde them full of errors. That (say they) is *sweete* that doth affect the Sense best, that is *bitter* which affects it worst.

Neither

Neither is true, for if that which is bitter did affect the Sense worst, no man would desire it, no man would take pleasure in it; for that which peruerteth the harmony of the Sense, may in some respect at least be pleasant vnto him, but that which doth affect the Sense worst must needs make the instrument to iarre; and yet we know that many men (not to speake of other creatures) doe wonderfully delight and vehemently long after those things which are bitter.

Againe, if sweet were that which affecteth the Sense best, then should it please all men, yea all creatures, for that which affecteth the Sense best we should most reioyce in, which notwithstanding we finde to be contrary oftentimes in our selues, when nothing is more irksome vnto vs then that which is sweet and luscious.

But some men may aske me (if I doe not like these definitions) how I would haue sweet and bitter defined. I answer (as I said before) that they cannot bee defined; for accidents doe not fall vnder definition, especially second qualities which are more accidentary then the first: and therefore I thinke they cannot be so much as described, vnlesse you will take that for a description which is most common, and when there hapneth any exception it shall be said (and that more truly then they are aware) that it happens by accident, that is to say, not because the Taste doth not agree with a description, but because there is some fault in the Organ which doth not perceiue the Sapor as it is.

Well, we will confesse that these Sapor being the extreames, may fall vnder some such rude description as is before exhibited; but whose penill can draw so fine a line as to describe the intermediate Tastes? Shall we make one for all, and say that those are intermediate Sapor which affect the Taste after a middle manner?

Surely this definition had not neede to be scanned in the Schooles, being made at random or at large without any causes or signes of causes therein.

Much better it is in my opinion to note them out by examples or instances, as *Galen* hath wisely done in the eight and ninth Chapters of his fourth Booke *de medicam. facult.* A sweet Sapor therefore doth consist in a matter abundantly moyst and moderately hot: as are Figges, Hony, ripe Grapes, sweet and mellow Apples and suchlike. The bitter Sapor resideth in a very crasse and thicke matter; hot indeed but moderately moyst, yea rather drye as Wormwood, Gall, Aloes and suchlike. A fat Sapor consisteth in a thin matter and ayry, which also is temperate in the first qualities as is Seame, Marrow, Oyle, Milke, Butter and suchlike. A salt Sapor consisteth in a dry matter, as in Salt, Ashes, Gun-powder and the like. A keene Sapor is in a substance whose parts are thin and subtile, yet moyst and the temper hot; such a taste is in Garlick, Onions, Raddish and the like. A sowre taste which also they call stipticke and *Sapor ponticus* (but I knowe not why) is in a crasse and cold matter, as in vnripe Apples and Berries or suchlike. An acute or byting Sapor is when the parts are thin subtile, dry and hot, as Pepper and Ginger. The sharpe is in thin parts but cold, as in Vineger, Lemons, oyle of Vitrioll and suchlike. Finally, you may with me obserue that no man; (for ought I know) hath hitherto sufficiently described these maister Sapor, nay not so much as giuen them apt and fit names, the confusion wherof do make the discourse of them tedious to the Reader. Onely *Galen* hath chalked out a faire way, wherein if we carefully insist, happily this labyrinth may at length be troden out. We conclude therefore, that if it be impossible rightly to define these heads, hard to describe them, very difficult to giue them proper names, what an infinite taske were it to vndertake an exact discourse concerning all the particular differences of Sapor?

QVEST. LXI.

Of the Medium or Meane of Tasting.

WE are againe false into a hard and intricate way wherein none of the Ancients or of the new writers haue beaten out a pathe vnto vs, and that is concerning the medium of Tasting. *Aristotle* was in a great suspence concerning the medium of Touching, neither did he determine any thing thereof. In like manner concerning this of Tasting he hath vtterly forsaken vs. And I wonder much (saith *Placentinus*) that amongst all the Philosophers there is not one that hath insisted in this disquisition to finde out the truth; but those that haue particularly made Tractates of this Sense haue notwithstanding balked this argument, not considering that in euery Sense there be three things especially to be stood vpon, the Object, the Medium and the Organ.

Philosophers
faile therein.
Arist. toucht
vpon it.

Concerning the object and the Organ all men do agree, and the cry is vniforme and current. But for the *Medium* there all the whole field is at a losse. Haply the difficulty of the Disquisition did affright them, for otherwise the contemplation is not vnpleasant. *Aristotle* toucht vpon it in the 101. Text of his second Booke *de anima* where he saith, That the Taste hath no external *Medium* because it is a kind of *Touching* which it selfe hath no such *Medium*. Beside this, he hath nothing of this matter; notwithstanding we will aduenture to put forth our selues vnder the censure of this carping age, which if we shall not satisfie, yet

Si non datur ultra, est aliquid prodire tenus.

If further forth we cannot go,
Yet something 'tis the way to show.

And haply he that comes after, as it is in new discoueries, may not repent him that we haue founded the Shore.

The taste needeth no *medium*.

First therefore we enquire whether this Sense doe neede a *Medium* or no. To speake ingenuously and as I thinke (saith *Placentinus*) it hath no absolute neede, neither shall it be materiall to distinguish between an externall and an internal *medium*, because we thinke that neither is necessary seeing the Taste which is a kind of Touch is immediately absolued or perfected as the Touch is. That which we Taste we immediately touch with our Tongues, neither is there Sensation made till the object light vpon the Organ. If any man shall imagine that there must be a *Medium*, I aske the question what he will assigne. One of the foure Elements or some body compounded of them? Surely neither these nor that. For if it be an Element it must be Fire, or Aire, or Water, or Earth. But not Fire, for that is hot and dry, which would not conserue but consume the moisture wherein especially the object of taste is seated. Now the office of a *medium* is to conserue the Object not to destroy it.

No Element
can be the
Medium.
Not Fire.

Adde hereto, that the efficient cause of Savors is heate, but one and the same cannot be the efficient cause and *Medium* of the same thing. Againe, if Fire were the *Medium* we might like a Salamander liue in the Fire, or champe burning coales and not be hurt.

Not Ayre.

The Aire is not fit for this function, for the Sapor resideth in the mixt body out of which it neuer yssueth, wherefore the *Medium* that must leade the Sapor vnto the Organ must also transport vnto the organ the mixt body wherein the Sapor is, but the Aire being a simple and liquid Element is not fit to carry a solid matter.

Not Water.

The Water cannot be the *Medium*, because we do not liue in it, and therefore it is not contiguous with the Object and the Organ.

Not Earth.

Much lesse the Earth, for that is cold and dry, both which qualities are contrary vnto Savors, and therefore will rather vtterly destroy them then conserue and maintaine them.

There are no
pure Elements

One word might haue serued all, There are no pure or simple Elements, and that which is nor cannot be a *Medium*.

No compound
body.

Is it any compounded body? No, for a compound body would disturbe and hinder the Taste. Beside, every mixt body if it haue neuer so little humidity in it, is of it selfe gustable, that is, the object not the medium of Taste. We conclude therefore that taste is made without any outward medium. Yet we doe not say that Taste is made without any intermediate Body adioyning to the organ of Taste. For as in touching we haue already said in the second Book that the scarf skin was made by nature to come between the object and the skin it selfe which was the organ, not to be a medium (for that office it doth not performe) but a little to dull the quality of the object; so likewise in Taste which we haue often said is a kinde of Touching, we hold that the membrane which inuesteth the tongue doth performe the same office to the organ, which therefore we may say is as it were a medium; though indeed and in truth it be not so.

What kind of
medium is ne-
cessary.

QUEST. LXII.
Of the Organ of Tasting.

Having thus said what wee could for this present concerning the medium of Tasting, we now come vnto the organ. Concerning which there is no doubt made, all men herein beleeuing their sense that the tongue is it which discerneth the differences of Savors. For not onely reasonable but all vnreasonable creatures, when they would taste any thing, doe lay it to their tongues:

tongues: or if they cannot doe so, they lay their tongues vnto it to distinguish the tast thereof. Some haue thought that the pallat is the instrument of this sense, which we find false, because those men whose pallats are eaten out with the French disease, doe yet taste their meate well enough. It must therefore be the tongue; though I am not ignorant that some haue attributed this faculty to the teeth, whose arguments haply we may answer in another place, if at least we shall not thinke them vnworthy our resolution.

That the Palate is not the Organ of Tasting. Nor the teeth.

But there are some who haue conceiued with better reason that the membrane which inuesteth the tongue is the true organ of Tasting: Among whom is *Valesius* in the foure and twentieth Chapter of the second booke of his controuersies. But hee affirms it onely, confirms it not, yet because so worthy a schollar hath affirmed it, wee will endeavour to make the contrary appeare.

Nor the membrane of the Tongue. *Valesius* refused.

First therefore the temperament which is common to it with other membranes doth deny it this priuiledge, for it is cold and dry, both which qualities are contrary vnto Savors. Now the qualities of the organ must not be at daggers drawing with the qualities of the obiekt, but rather friends, and liue neighbourly together, so as the organ may be potentially that which the obiekt is in deed and act.

The first Argument.

Againe, the same membrane which incompasseth the tongue, doth also inuest the nostrills, the pallat and the gullet. If therefore the membrane were the organ, this sense should be made in all these parts, which we find by experience not to be so. *Valesius* very vnadvisedly resolueth that this very membrane incompassing the nostrills is the organ of smelling, & saith, that it is the diuersity of the temperament which maketh it in the tongue the organ of the tasting, and in the nose the organ of smelling. But he is fowlyly deceived. For suppose it had in these places a different temperature, we must not thinke that only the temper is sufficient to distinguish the organs of senses: but beside to diuers actions there is required a diuers substance; diuerse I say, and such as is not elsewhere to be found: Now this membrane although the temper doe somewhat differ in seuerall places, yet in qualities and substance it is like it selfe appearing so, both to the sight and to the touch.

The second Argument.

Finally that is the principall part of the instrument into which a soft nerue doth determine, but into this coate no man will say the nerue doth determine who hath but touched Anatomy with his vpper lip; yet *Galen* in the second Chap. of his 16, booke *de usu partium* seemeth to affirme the same in these words. *As the hard nerues are inserted into the muscles, so are the soft into their proper Organ, as into the membrane of the tongue.* So that hence it might seeme to follow that this membrane is the proper instrument of Tasting. But this place of *Galen* is no whit against our opinion. For we thinke & confesse that that into which the nerue determines is the true organ. But *Galen* doth not say the nerue determines in the membrane, or coate of the tongue: he saith it is inserted into it, whence we may rather gather, yea therefrom it is conuincied that the substance of the tongue is the organ we treat of, because into it the nerues do determine: for being inserted into the membrane the extremity thereof reacheth vnto the substance of the tongue to defer and confer the faculty thereunto.

The third Argument.

Obiection out of *Galen*.

Galen expounded.

Obiection, Answer.

But it will be obiekted, that if this coate or membrane be ill affected the Taste is therewithall depraued. We yeeld it to be true: yet not because the Taste is perfected in that part, but because this membrane concurrerh to the action of Sensation, without which in deed we cannot Taste; so in the eye, if the Horny membrane be violated the sight is then depaured: and yet it doth not follow that the Horny membrane is the chiefe Organ of sight. And thus we must vnderstand *Galen* in the second Chapter of his 4. Booke *de locis affectis* where he saith that the Taste is vitiated if the membrane of the Tongue be distempered. Or we may say that this membrane is as it were the *Taster* to the *Taste*, which office it hath partly from his owne proper temperament, partly from the soft nerues which are inserted therein, vnlesse you will say that these nerues were allowed to the membrane by Nature to giue it an exquisite sense of Touching, whereof the Tongue stood in neede for the defence of his substance, which assertion will not be against reason.

Galen expounded.

We conclude therefore that the membrane of the Tongue hath an exact Sense of Touching, nor altogether deuoide of Tasting, not that it tasteth at all of it selfe, but being contiguous, yea continuall and growing to the substance of the Tongue, it concurrerh withall to the perfection of the action, so as without it the Sense of Tasting cannot be perfected nor accomplished.

The conclusion.

Notwithstanding, we finde another principall part to which, as this membrane, so all the other adiacent parts are substituted by Nature as helpers and handmaides, and that is

That the body
of the tongue
is the true Or-
gan.
Arguments.

the proper and spongy flesh or pulpe of the Tongue. For beside that it hath a substance such as you can nowhere finde the like in the whole body, the Temperament also thereof is apt to enertaine and receiue Sapours; for it is moyst and hot, neare of kinne vnto the Nature of a Savour, that it might more easily be altered thereby. And indeed for the making of this Sensation, it is necessary that the Organ should put on the nature of the object which *Aristotle* meaneth, when he saith that the Organ must potentially be the same thing which the object is actually, that so it might be altered and actually receiue the nature of the object; for how shall it iudge of the object vnlesse it doe put on the qualities thereof.

Adde hereto that it hath an ingenite humidity, that those objects which are potentially moyst, as Salt is, being by this organ actually made moyst might become sapide, that is, freely and frankly exhibite their Sapours.

Againe, what greater argument can there be, that this flesh should be the organ of Tasting then because it is spongy, for Taste is neuer made vnlesse the moysture that carrieth the Saviour be imbibed by the organ of Tasting, to which purpose nothing is so fit as the spongy pulpe of the Tongue. Moreover, al the other Senses are double, and therefore Nature, though she had great reason to make the Tongue single for the commodity of the voyce, and such other circumstances as we haue particularized in our History: yet that it might be after a sort double, she hath drawne a line through the middest whereby it is diuided into a right side and a left. On the manner there is no part in the mouth deuided, but in the mouth is the Sense of Taste, and therefore it must belong onely to the Tongue.

QUEST. LXIII.

Whether the Tongue alone doe Taste.

That it may be
communicated
to others.

WE haue proued that the Flesh or Pulp of the tongue is the true instrument of Tasting. Notwithstanding it is doubted whether this Action belong only to this part or may also be communicated vnto others. That it may be communicated to other parts; some arguments are vrged. First, the Taste is a kinde of Touching, but Touching is diffused through all the body. It may seeme therefore that the Taste is also diffused through more parts then one, especially so farre as the meate doth attaine, that is, into the Mouth, the Gullet and Stomacke.

Againe, there yssueth out of the Braine a soft nerue which is simple & single in his originall, but when it hath paced a little forward, from the skull it is deuided into two branches: whereof one is inserted into the Tongue, the other into the lower parts.

Thirdly, we see that the Stomacke doth reiect and cast vp some meates by vomit, others it embraceth and containeth.

In like manner the Gullet swallowes some meates well and freely, others not without loathing and much difficulty, yea some meates because of the enmity betwixt the Stomack and their Taste, euen after they are downe are cast vp againe.

It may therefore be demanded how this choyce can be made, this loathing or liking stirred vp, vnlesse we say that the Stomacke and the Gullet do Taste and distinguish the differences of Sapours.

Adde hereto the authority of *Aristotle*, who in the 11 chapter of his fourth Booke *De partibus animalium* saith, that Fishes in their swallowing do take pleasure and haue a sense of the meate that passeth into the Mawes. Without doubt these arguments are not to be contemned, and yet we will make answer vnto them.

Answer of the
first.

To the first we say, that though the Taste be a kinde of Touch, yet it is not necessary that it should in all conditions answer or be proportionable to the Touch.

To the second.

To the second, that although the Nerue which is inserted into the tongue do transmit another branch to the Gullet and the Stomacke, yet it doth not follow that the gullet and the Stomacke must taste, for the soft nerues do transport the faculty of sensation; yet that the Eye sees colours, the Eare heares sounds, the Nose perceiues odours or sanours, is not by reason of the Nerue, but because of the disposition and temperament of the organs. For the faculty of sensation is euery where one and the same, neither is there any difference in the faculty whereby we heare, from the faculty whereby we smell, or from the faculty whereby we taste: but all the difference ariseth from the disposition of the organ. The Foote would see, and the Elbow would heare, and the sides would smell, and the crowne would taste, if in these parts there were a disposition to receiue the objects of these Senses.

The differences
of the senses
depend
on the diversities
of the Organs.

In like manner, although the Gullet and the Stomack do receiue a soft Nerue, yet the Gullet and the Stomacke do not Taste because they are not disposed thereto. But the Reason why Nature hath giuen them this soft Nerue we may finde in *Galen* 2 chap. of his 16 booke *de vſu partium*, to wit, because they stood in neede of an exactnesse of sensation. Now (saith *Galen*) those parts which had need of exact Sense, haue all of them receiued soft Nerues.

From this that hath been said, we may shape answers vnto the rest of the arguments. That the Gullet swallowes some meats, and loaths others; that the Stomacke retaines some meats and casts vp others, we ascribe vnto the pleasure or paine which they feele from the tactile qualities: for of the parts of the body of man none hath the Sense of touching so exquisite as the Stomacke. For beside that it is membranous it hath an infinite number of branches of Nerues inserted therein, that it is no wonder if it kicke against the least offence. So if wee thrust our fingers into our throats we can procure a Vomit, not that we make our Stomacke loath any thing, but because the Tactile qualities doe vrge and prouoke a sensible part. We also may say, that because of the contiguity of parts the Stomacke is fore-warned by the Tongue, so that the Tongue perceiuing any horrid or vnpleasant sauour communicateth the Sensation to the stomacke, forwarning it of an approaching enemy, which thereupon stirring vp it selfe as it were to battell, yerkeeth against it and casteth it forth. And to say true, there is such an instinct in Nature bred and seled in those parts. For we may not attribute the sense of Tasting to the Gullet or Stomacke, because if these parts had Taste, the sicke man that takes a pill or Boile wrapt vp in Sugar would neuer retaine it, which if he take without Sugar hee presently casts vp againe: and the reason is, because when they are not rowled in Sugar or otherwise made sweet, their bitter or vnpleasant Sapour is perceiued by the Tongue, and warning thereof giuen to the Stomacke. They are retained being sweetned because that till Taste is obscured and so the Tongue deceived. Being now arriued into the Gullet or the Stomack although the Sugar melt from them yet they are not cast vp againe, because the stomack doth not perceiue their Sapour. And this is the reason why when we would let downe any vnſauoury thing into the stomacke we endeouour not to touch the Tongue more then of necessity, least it should be prouoked thereby. We conclude therefore, that neither the Gullet nor the Stomacke do perceiue Tasts or Sapers but onely the Tongue.

To the third.

Why the Stomacke casts vp some meat and retaines other. Another answer to the Argument. Of the swallowing of Pills.

QUEST. LXIII.

In what part of the Tongue the Taste is most exact.

Having found out the Organ of Tasting, it remaineth in the last place to search in what part of the Tongue the sense is most exact, for there is no question but there is a great difference.

There are some reasons to perswade vs that the backpart of the tongue doth taste better then the forepart. First, because at the back-part of the Tongue the Almonds are seated on either side which doe receiue the spittle and a great quantity of moyſture: wherefore because the spittle doth helpe this sense very much, it is to be imagined that where there is most spittle there is best Tasting. Again, the Nerues which are inserted into the backside of the Tongue are greater then those which are inserted into the foreside. Yet *Aristotle* holdeth the contrary and proues his assertion to be better, for what can be more certaine then experience.

That the back part tasteth best.

If therefore we desire to Taste any thing more curiously we apply it to the tip of our tongues, and if it fall toward the roote we call it backe againe. Again, when we are to swallow any thing whose taste is displeasing to vs, we hasten it to the roots of our tongue as soone as we can. The reason is, because the sense of Tasting is not there so exquisite. Moreover, it is very reasonable that the Taste should be more perfect in the fore-part, because this sense was allowed to the creature to discern hurtfull Tasts and to auoid them. But if the perfection of the Taste had beene at the roots, that which is offensive might haue slipped downe before we were aware, whereas the tip of the Tongue discerning the difference best, is also best able to free it selfe from that wherewith it is offended. Adde hereto, that the forepart of the Tongue is softer, more spongy and better disposed to imbibe the humidity wherein the Sapour is contained.

The contrary opinion. Aristotle. Reasons.

We conclude therefore, that the perfection of the Taste is not in the roots but in the tip of the Tongue.

The

Answer to
the former
Arguments.

The arguments that were brought to prooue the contrary may be answered. For because there is so great a plenty of moisture at the roots of the Tongue, therefore the best Taste should not be there; for superfluous humidity doth not quicken the Taste but dulles it.

Neither do we deny but that the Nerue is larger at the roote of the Tongue, but it doth not follow that therefore the Taste is there more perfect, because in the fore-part though the Nerues be lesse, yet they be more plentifull and abundant, and there do cause the Taste to be more perfect.

And thus we are come vnto an end of these Labyrinths concerning the Senses, wherein we haue beene somewhat the more prolix, that those which loue the contemplative part of Philosophy might haue something wherewith to please their appetites. It is true indeede that there are many passages in these Controuersies, which for the most part we haue taken our of *Iulius Casserius Placentinus*, which might well haue befitted the Schooles themselves,

but we imagine that these our Labours may haply fall into some mens hands who will be willing to recognize those Studies which for better employments they haue intermitted. A very few of which kinde if I shall giue contentment vnto, I

will not thinke my labour ill bestowed. Other men who do not vnderstand them, or else are better able then my selfe to satisfie

themselves, may turne ouer to that which shall be more

fittig for their Dispositions. And so we will

leauē the Head and Senses, and come

vnto the Ioynts.

THE NINTH BOOKE.
Wherein the Ioyntes are briefly
Described.

The Præface.

IN the whole body of Man there is nothing more wonderful then the structure and position of the Ioynts, nor any thing wherein a man doth so much differ from all other creatures. The bowels are most what a like in all, both for Nutrition, Generation, Life and Sense, because all creatures have like vse of all those parts as well reasonable as vnreasonable. The only thing which makes the difference is the Reasonable Soule which is inuisible, a Nature transcendent and aboue the Nature of the body. Next to that, the fashion and position of the Ioynts whereby the body is lifted vp from the earth (vpon which the other creatures doe grouel) maketh the greatest difference between man and beast. It were a world of wonder to enter into discourse of the particular Reasons of this position, and we haue partly handled them before in the first Booke, but especially we purpose to prosecute them in this ninth Booke destined to that purpose.

Galen hath taken especiall paines in this argument appropriating thereunto his three first Bookes *de vsu partium*, wherein he hath preuented any man that should take paines after him.

We shall thinke we haue quit our selues well if we can in some sort abbreviate those large Volumes in this place, wherein we haue laboured so much the more to be as concise

as the subiect matter will giue vs leaue, because all the particulars will fall vnder our discourse in our bookes of the Muscles the Vessels and the Bones. The

Reader therefore is to be intreated to content himselfe with this

bare ouerture, wherein we will but muster the parts close

together, because we shall haue time and scope to

draw out our troopes and to marshiall them

in better order, when we come into

the large fields of the Bookes

which follow.

CHAP.

CHAP. I.

A brieft description of the Ioynts.

E before deuided the body of Man into three Regions or Venters, and the outward parts or the Ioynts. Through the three Regions, Naturall, Vitall and Animall, we haue carried our Story with as great breuity and perspicuity as wee could, it followeth now that we prosecute our History vnto the Limmes. The Ioynts therefore which grow vnto the body as boughs vnto the trunk of the tree are called in Greeke *κῶνα* and *γῆνα*, in Latine *artus ab artando*, in English we will call them Limmes or Ioynts, because there are most ioynts in them.

Two kinds
of ioynts.

The diuision
of the hand.

There are therefore two kinds of Ioynts, the vpper and the lower; the vpper ioynts are called by the common name of the *Hand*, for the Ancients accounted the whole member from the shoulder to the fingers ends to be all the *Hand*. The lower Ioynts are likewise called *Pedes*, that is, the *Feete*, of which we shall speake afterward. The whole *Hand* *Hippocrates* and *Galen* doe deuide into three parts in *Brachium*, *Cubitus*, and *summam* or *extremam manum*, that is, the *Arme*, the *Cubit* and the *Hand* as we vse to call it.

The arme.

The *Arme* *Celsus* calleth *humerus*, *Festus* calleth it *Armus*, whence our word came. The Head which is inserted into the broad bone or blade of the shoulder is called by *Pollux* *ἐκφυλῖς*, by *Euripides* *ἐπαυρίς*, the end is called *ἀκρωτήριον*.

The cavity vnder the ioynt of the shoulder *Aristotle* called *axilla*, commonly *ala*, because in it do grow hayres as feathers in a wing which is called *ala*, and we call it the *arme-hole*.

The Cubite?

The second or middle part is called in Greeke *πῦξ* or *ἀγκύον*, in Latine *Cubitus* or *Vlna*, we will call it the *Cubite* to distinguish it from the vpper part which we call the *Arme*.

The hand.

The third part is called *Manus*, from *manare* to flow, because it floweth as it were out of the *Cubit*; this we call properly the *Hand*, and it hath three parts, the wrest called *brachiale*, the After-wrest called *post-brachiale*, and the fingers called *digiti*, of which we shall speake in their due place. And this is the common diuision of this ioynt. Wee now will follow the particular parts of the diuision.

CHAP. II.

Of the parts of this Ioynt in generall.

The veines of
the whole
hand.

He proper parts of the whole *Hand* taking it in the large acception of the Ancients, are beside the common parts which we pretermit, the *Vessels*, the *Muscles* and the *Bones*. By the *Vessels* I vnderstand the *Veines*, the *Arteries* and the *Nerues*. The *Veines* which are deriued through this whole member doe arise all from the *Axillary* branch: and there are two, the first passeth along on the inside, the other on the outside of the *arme*. That on the inside is called *Basilica*, that on the outside is called *Cephalica*. The *Basilica* *Hippocrates* calleth *Venam internam* the inward veine. Others call it *Hepatica* and *Iecoraria*, that is the *Liuver-veine*. And it is ordinarily deuided into a deeper and a shallower. The deeper climbing ouer the axillary Artery and the third paire of sinewes passeth along to the bough of the *Arme* which we commonly call the *Elbow*; and so bestoweth his branches vpon both the bones of the *Cubite*.

Basilica.
The Liuer-
veine.

The shallower runneth vnder the skin to the ioyning of the *Cubite* with the *Arme* where it is clouen into two boughes, one of which passeth to the inside of the *Cubite*, and there is vnited with a branch of the humerary veine, and from that coniunction ariseth the *Common veine* which they commonly call *Mediana* or the middle veine; the *Arabians* call it the *black veine*. The other bough descendeth along the lower side of the *Cubite* sprinkling the skin and parts by which it passeth with diuers small branches.

Mediana.

The blacke-
veine.

Cephalica or
the head veine.

The *Cephalica* or *Head-veine* so called, because it is opened in diseases of the *Head*; *Hippocrates* calleth *externa* or the outward veine, because it creepeth along the outside of the *arme*: others call it *Humeraria*, (because it passeth through the shoulder betwixt the Muscle called *Deltoides* and the Tendon or chord of the *Pectorall* muscle) which falling down vnder the surface of the skinn, when it commeth vnto the bough of the *Cubite* is deuided into two branches; the one borne along obliquely into the inside of the *Cubite* coupleth it selfe with the branch of the *Liuver-veine*, and betwixt them beget the common or middle *Veyne*; the other which is larger descendeth by the *Radius* almost to the middest there of.

of and hence running obliquely to the wrist, it watereth almost all the backe of the hand, and endeth in a notable and manifest branch, betwixt the little and the ring finger: where it is called *saluatella*, and is opened, as authors say, with good successe in spleneticke persons.

Saluatella.

The Arteries of the hand.

The arteries which belong to this hand doe proceede in one bough from the axillary artery, and this bough is called *Basilica*. It hath two branches, one ferled deeply. the other eminent between the skin and the flesh. Both of them do afford many deriuations out of themselves, but that of the shallower is most notable which is oftentimes to be seene in the inside of the wrist a little about the roote of the thumbe, at which place and by which artery we vse to feele the pulse to find out the differences thereof.

The pulse.

And for sinewes there are six paire disseminated through the whole hand, the first commeth out of the first racke bone of the necke and is spent in the Deltoides muscle and the skin neere vnto it. The second arising from the first racke bone of the necke first passeth into the double headed muscle; then it casteth off a small branch to the long muscle of the Cubite, and at length when it attaineth to the elbow it is diuided into branches. The third being mingled with the second, reacheth his helpe to the muscle of the arme, which lyeth vnder that with a double head. The fourth which is the largest of all the rest falling vnto the same muscle together with the deepe liuer-veine and the inward artery is deuised into diuers branches. The first passeth along betwixt the muscles, which bend and extend the cubit, and hauing gotten ouer behind the inward proceffe of the arme, and being mixed with the third coniugation, is consumed in the fingers, giuing to the little finger two nerues, to the ring finger likewise two and to the middle finger one. The sixth paire sliding downe between the skin and the neruous membrane by the inward proceffe of the arme determineth into the skin of the Cubite. And these are the vessels of the whole hand whose description we shal more exactly set downe in a fitter place hereafter. The muscles of the whole hand are very many, some moue the Arme, some the Cubit, some the Radius, some the wrist and some the fingers, of which also we shal speake in their proper place. The bones of the hand are diuers, the arme hath one bone, the cubit two, the wrist eight, the afterwrist foure, the fingers fifteen, to which we may adde if we please the small seede bones called *Sesamoidea*, all which we wil as curiously and accurately as we are able describe in our booke of the bones, whither at this time we refer the reader.

CHAP. III.

Of the excellency of the hands.

Man, who is the crowne and pride of Nature, that bold and confident worke-Mistrisse, him I say, God on his birth day, did cast out vpon the dust of the earth, naked, vnarmed, and weltring in his blood, to enioy or rather to deplore an inheritance of sorrow and misery. Yet notwithstanding because he is sent into the world to be a combatant and not a sluggard, he hath armed him with two wondrous weapons, which he hath denied to all other living creatures, Reason and the Hand. His reason is the storehouse of all arts and sciences, the first ground-worke and foundation of whatsoeuer the immortall soule is naturally capeable or apprehensue of; an Art it is, as before all Arts, so hath it all Arts for his subiect or matter whereabout it is occupied. The hand is an instrument, but as it is the first instrument so it is the framer, yea and imployer of all other instruments. For not being framed for any one particular vse it was capeable of all: so as it may iustly be compared to the soule, which as the Philosopher saith is, though not in deed yet in power and ability all things. By the help of the hand Lawes are written, Temples built for the seruice of our maker, ships, houses, instruments, and all kind of weapons are formed. I list not to stand vpon the nice skill of painting, drawing, caruing, and such like right noble Arts, whereby many of the Ancients haue made their names honorable vnto vs, yea and eternized them to the worlds end. By our hands we promise, we call, we dismisse, we threaten, we intreate, we abhorre, wee feare, yea and by our hands we can aske a question. By the helpe of the hand although a man be borne vnarmed, yet is he able to safeguard himselfe from all other creatures: and all those creatures which come strong and armed at point into the world, how fierce soeuer they be, how able to abide the violence of heauen it self, yet are they not safe from the hands of men. For doth not the industry of mens hands preuaile against the hornes of the Bull, the teeth of the Lyon, and the paw of the Beare? yea whatsoeuer is comprehended vnder the cope of heauen, by the skill of the hand is brought vnder our subiection and made tributary vnto vs.

Man is the glory of Nature, whose workes shew his manship.

The weapons which man hath more then other creatures. What a man can doe with his hand.

And

Anaxagoras.

And therefore *Anaxagoras* as *Plutarch* reporteth, marking diligently the curious fabrick of the hands, the postures of the fingers, as they moue either together or apart, the mighty strength, the cleane nimblenesse and the soft delicacy thereof, ascribed vnto them the cause and originall of mans wisdom. How much wiser was *Galen*, who in those melodious Hymnes which he wrote to the praise of his Creator, I meane his Bookes of the Vse of Parts, discoursing very curiously concerning this curious instrument concludeth. That man is not therefore the wisest of all creatures because he hath Hands, but because he is the wisest of all creatures, therefore Nature furnished him with this excellent instrument. It was not the Hand that taught men Arts but Reason, yet the seruant and minister of this reason and wisdom is the Hand: they are the Vicars or Substitutes and Suffraganes of the speech, the interpreters of the secret Language of our silent conceits, signifying to all men in a few Letters as it were by Hieroglyphicks what the very thoughts of our Hearts are.

Galen.

The Hands
consecrated
to Faith.

Numa Pompilius consecrated the Hands to Faith, and therefore all Compacts, Couenants, Truces and enter-courses whatsoever are held inuolably ratified by the very touch of the Hand, and at this day in our neighbour-countries the Principall Nobility do sweare their allegiance into the Hands of their Prince or his Substitute.

The Hands
Emblems of
Fortitude.The vanity of
Chyroman-
tickes.

That very Touch was also among the *Persians*, the most sacred pledge of fidelity: and therefore the most Ancient did vse to salute one another on this manner, giuing and receiuing honor by this part. Likewise they which adore Princes or great Potentates are accustomed to kisse their Hand and incline their head. In the Egyptian Hieroglyphicks the Hand was the Embleme of Fortitude, and therefore they which seeke for helpe do call for the right hand, for so it is in our common Prouerbe, *Lend me your helping Hand*. I list not to commend the Hand from that superstitious Art or Imposture rather of such as call themselves *Chyroman-tickes*, whose idle speculations are not fit to be mingled with our serious discourse, which we will now transerre from the excellency and commendation of so curious an Instrument to a more Anatomicall consideration of the Vse, Figure and Structure of the same.

CHAP. III.

Of the Vse, Figure and Structure of the Hand properly so called.

The generall
vses of the
Hand.

HE true office of the Hand is to apprehend or to hold, and his proper action is apprehension (for *Hand* and *Holde* are Coniugates as we terme them in Schooles) from whence it is called *Organum* ἀρσενικόν, The First vse therefore of the Hand is to take hold. Another vse of it is to be the iudge and discerner of the Touch. For albeit this touching vertue or tactile quality be diffused through the whole body both within and without, as being the foundation of the Animall Being, which may be called *Animality*, yet we doe more curiously and exquisitely feeble and discern both the first and second qualities which strike the Sense in the Hand then in other parts. It is also an Instrument wel fitted to ease our paynes, to propulse or driue backe iniuries and to defend the fore-parts of the body. Wherefore for these vses and for the performance of all his functions it hath that figure which we see, and that admirable structure which as well as we can, we shall vnfold vnto you.

The hand the
Instrument of
Touching.The figure of
the Hand.

Why diuided.

The Figure is long and diuided into many parts that it might comprehend in one all kinde of Figures, the round or Spherick, the right and the hollow, for all figures are made of three lines, a crooked, an hollow, and a straight. Beside, this figure doth equally apprehend both greater bodies and lesse; for small things it holdeth with the ends of two fingers, the great finger or the thumbe and the fore-finger, If the body be a little bigger, it containeth it with the same fingers but not with the ends. If it be yet bigger, we vse three fingers, the thumbe, the fore and the middle fingers. If it be larger then we can containe with three, we vse foure, and so fise, and at length the whole hand. Now if the Hand had been made of one continuall peece, it would onely haue apprehended a body of one magnitude. Neither was it sufficient that the Hand should be diuided into fingers, valesse the same fingers had been placed in a diuers order and not in the same right line, so as one was to be set or opposed to the other foure, which being bowed with a small flection might meete and agree with the action of the other foure opposite vnto it. And this is the manner and proportion of the figure.

The structure
of the Hand.

For the structure if it be diligently attended, it will imprint in vs an admiration of the wonderfull

wonderfull skill and workman ship of Nature, and it is on this maner. Because the Hand was the most noble and perfect organ or instrument of the body: God the Creator moulded it vp of diuers particles, all which for our better vnderstanding we wil referre vnto 4. kinds.

The first kind is of those which originally and *by themselves* do performe an action; the 2. of those without which an action is not performed: the 3. of such as do more perfectly accomplish an action, and the last of such particles as do preferue an action.

The 1. and principall part of the hand is a muscle, because there is no apprehension without motion; now we know that a muscle is the immediate organ of voluntary motion,

The principall part of the hand is the muscle.

The 2. part without which there is no apprehension is a nerue; for the muscle moueth not vnlesse it be commanded, this commandement the nerue bringeth together with a subtile spirit, and therefore it is called *Lator* or the poast.

The 3. which accomplish the action are the Bones and the Nayles: the Bones do make the action strong and stable, without which the Fingers might indeed be extended & bent againe, but because of their softnesse they would euer haue beene trembling, and not able to haue holden any thing straight or firmly.

The bones and nailes do make the action perfect.

The Nayles further apprehension. The particles which do preferue the action are the veins, Arteries, the Skinne and the Fat. The Veines water it with blood; the Arteries quicken it with vitall spirit; the Skin and the Fat make a *Colligation* or tying together of all the rest.

CHAP. V.

Wherein is declared the reason of the framing of all the Similar parts whereof the Hand is compounded.

THe Muscle therefore is the principall part of the Hand by which immediatly apprehension is made. But because there are two especiall parts of a muscle, the Flesh and the Tendon or Chord, Nature placed many tendons and litle flesh vpon the fingers, because the end of the hand should be light and thin, not heavy and thicke.

Why the fingers haue litle flesh.

These tendons from their originall euen to their insertion are round; that they might be lesse subiect to outward affects, but in the very insertion they grow broader that the motion may bee more nimble. But because there are many motions of the fingers, to wit, right, as simple; flexion or extention; and oblique when they are brought together or parted asunder; it was necessary that there should be tendons both without and within and on the sides of the fingers. But how many muscles there be of the Hand, whence euery one of them ariseth and where they are inserted together, with their structure, we shall declare in the next Booke wherein we handle of sette purpose the History of all the muscles.

The tendons of the fingers.

Nerues they haue disperfed into their muscles and flesh, and those very many from the 4. and 5. paire of the Arme which yeeld vnto them the faculties of Sense and Motion. The Bones of the Hand are 8. of the Wrest, 4. of the After-wrest which are tyed together with a strict and immouable articulation or iuncture. The Bones of the Fingers are ioyned by *Diarthrosis*, for it behooued that they should so moue as they might be able to apprehend or take hold of all figures or fashions of things. These Bones are only 3. neither more nor lesse, for more would haue hindered perfect extention, and fewer would not haue admitted so many and diuers particular figures. And all these that the motion might be more facile and easy, are knit together by *Ginglymos*. Now the variety of the motions is furthered both by the gristle which compasseth their extremities, and by the fat and oyle humor which like a slime doth line the ioynts. But because when the creature according to his pleasure shall bend and bow these ioynts, they should not be disseuered or fall out of their seates, Nature hath knitte them together with iyes and bands, and wedged them in also with small bones like *Sesamum* seeds. For these small bones which are in the inner ioynts of the Hand, do not suffer the ioynts to *Luxe* or shoote inward when wee stretch out our hands strongly; and those that are placed in the outward ioynts keepe them from leaping outward when wee bend our Hands with violence.

Their nerues.

Their bones.

The iyes or bands.

The seed bones and their vse.

The further discourse of the Bones of the Hand you shall finde hereafter in the last Booke which is of the Bones: for to transcribe euery particular here, were to abuse my owne time and your patience.

The bones therefore do make the action more perfect. For if the fingers were without them, we should be able to performe those actions only wherein it behoued vs to draw the fingers

The vse of the
Nayles.

into a circular forme. The nayles also were made to further the vse of the hand; for hard and small bodies would easily fly from the fingers, vnlesse there had beene set to their ends a hard body, both to strengthen and establishe the flesh, as also to keepe in and retaine such small and slippery thing. Finally the veines,,arteries,skin,and fat, do preserue or conserue the action.

CHAP. VI.

More distinctly of the dissimilar parts of the Hand, of the Wrist
and of the After-wrist.

The wrist.

He Hand properly so called, hath three dissimilar parts: the Wrist, the After-wrist and the Fingers. The Wrist called *Carpus*, the Latins more vsually call *Brachiale*, the Arabians *Rafeta* or *Roseta*, because it was a custome to adorn that part with Roses, & diuers flowers. It consisteth of eight bones set in two ranks, which haue no proper

The afterwrist

names belonging vnto them. The After-wrist called by the Latins *post-brachiale* and by *Celsus* *Palma*, is deuided into two parts, the internall and the externall: the internall part which makes the hand hollow when it is stretched forth, hath his name in *Hippocrates* from a word which signifieth a stroke, because with the palme we vse to strike. The Latins call it properly *Palma*,

The palme.

and so doe we the Palme of the hand: which when it is crooked and hollowed is called *vola manus*. The outward part which is the backe of the hand is called *manus auersa* or *dorsum ma-*

The backe of
the hand.

mus. In the Palme of the hand there are many particles obserued. For the beginning of it which riseth a little toward the inside of the wrist is called *Radix manus* the roote of the hand. The

The hillocks
of the hand.

middle part is called *Interstitium* or the partition. The fleshy swellings which the Chyromanticks call hillocks or monticles doe make the brawne or pulpe of the hand and are called properly *Siyapa* of a word which signifieth to smite. That hillocke which is vnder the thumbe is called *mons martis*, that vnder the fourth finger, *mons Iouis*, that vnder the middle finger, *Saturni*, that vnder the ring finger *Solis*, that vnder the little finger is dedicated to *Venus*. The

The lines.

Thenar that is the space which is betwixt the thumbe and the fore finger is called the hill of *Mercury*: and the *Hypothenar* which is the brawne betweene the roote of the thumbe and the little finger is called the *Moone hill*. Beside these, there are also in the *Vola* or cup of the

The line of life

hand many lines, by the sight and obseruation whereof, the Chyromanticks doe promise and take vpon them, to foretell the length or shortnesse of the life, good or euill fortune, Naturall inclinations, and in a word the euents of all accidents: with how great reason or from what cause or ground either in Nature or in diuinity, *ipsi viderint*: we wil only for distinction sake, and because it is rather lookt for at our hands then that we approue any such impostures, name them vnto you. They are said to be fourteene, but three are principall: the first which com-

The naturall
line.

passeth in the thumbe is called *Vitifera* the lyne of lif, by others *Temporalis*, or the line of tyme. The second which runs ouerthwart through the midst of the *Vola* or cup is stretched

The table line
or line of venus

to the moone hill, and is called *Iecoraria* the Liuer line or the naturall lyne. The third beginneth from the *Hypothenar* or moone hill, and reacheth to the mount of *Iupiter* and is called the table or bed lyne of *Venus*.

Why 2. hands.

When the hand is shut it is called *Pugnus*, or the fist; when it is halfe bent it is called *condylus*. Further we must obserue that Nature hath made two hands, one to helpe and assist the other, the right, and the left. Some there bee which can as well vse this as that, and are called *Ambidextri*. A woman saith *Hippocrates* cannot be an ambidexter, that is, she cannot vse both hands alike.

CHAP. VII.

Of the Fingers of the Hand.

The parts of
the fingers.

He last part of the hand containes the Fingers, called *digiti*, whose order and rank is called *Phalanx*; the internall articulations or ioynts are called *internodia*, the knots of the fingers. The fingers ends which are round and fleshy are called *Vnea* or the grapes. The outer part of the fingers haue knubby or knotty ioynts cald in

Why 5. fingers
and no more.

Latin *Nodi*, wee call them knuckles, and there are three in euery finger. Each hand hath five fingers.

fingers, neyther more nor lesse, that the apprehension might be more perfect. For take away the thumbe, and you take away the power and strength of all the rest: if you take away the little finger you cannot incompasse any thing circularly. Now these fingers were made vnequall in length and magnitude that we might the better comprehend all figures and all quantities both greater and lesse. The first, because in strength it is equipollent or equivalent to all the rest, is called *pollex* or the Thumb and hath only two ioints. And this finger hath peculiar muscles, bending, extending and leading it too and fro, because it hath something peculiar in his motions. The second is called *Index* from his vse, because we vse it when we would shew any thing. *Suetonius* calleth it *Salutaris*, it hath a Greek name also from a word which signifieth to licke, because with it we vse to taste or like any thing. The third is called *Medius* or *Famosus*, the middle from his situation, *Famosus* because by stretching this finger forth we vse to deride or disgrace when we list.

The Thumbe.

The for finger

The middle-finger.

The fourth is called *Medicus*, because therewith in old time they vsed to mingle or stir medicines; tis also called *Annularis* or the Ring finger, because the Rings are there most commonly woine. The fift, because it is the least is called *Minimus*, and *Auricularis* because with it we picke our eares. Every finger hath three bones ioyned by *Ginglymos*, as we shal say hereafter. Finally, for more steddy apprehension there are nailes set vnto the fingers ends engendred of the more crasse and thicke excrements of the third concoction, and therefore they grow continually only in length as do the haire. But their growth is not by nourishment but by an imperfect accruing of the matter, for there is no traction or assimilation of aliment, but only an apposition of excrement.

The Ring finger.

The little finger.

The nature of the Nailes.

They are moderately hard that they might not be hurt with outward things rushing against them and also round for their further security, the Latins call them *Vngues*, their roote which is like a white moon is called *Radix* or *Ortus*: the tops which we pare off, *Extremitas*, the white spotted in the naile *Mendacia*, so many spots so many lies. And this shall suffice for the description of the vpper ioynts, now follow the lower.

The parts of the Nailes.

CHAP. VIII.

Of the Foot in Generall, his Excellency, Figure, Structure and Vse.

Man alone, because he was the wisest creature had Hands giuen vnto him the first and originall instruments of the world, so hee alone of all creatures which dwell vpon the earth and vse feete onely, hath two feete answerable to his two Hands; for if hee stood groueling on foure stiltes, how could hee ride, write, build, throw a weapon, or exercise any of those Arts wherewith hee is furnished? The Figure and posture of brute beasts had beene altogether vnprofitable and incommodious for this Diuine Creature, for neyther could he haue looked vp to Heauen, for which cause euen *Anaxagoras* could say that hee was created; nor sit him down to meditate, for they say, that the sitting Soule is the wisest; neyther could he passe through sharpe vnequal or sloping places, climbe Turrets, build houses, or any such thing. It is true, that the more feete the swifter is the creature (other things being equall,) but what need had man of such footemanship to overtake, when by his industry he is able to circumuent all other creatures? Hee was therefore made *Bipes* that is, with two feet, and therefore he standeth vpriight or sitteth at his pleasure.

Why a man hath but two feete.

The proper vse of the foote is to walke and the action is walking, and therefore the foote is called *Instrumentum ambulatorium* or a walking Instrument. This walking is when one Legge resteth vpon the ground, and the other is brought about forward. The resting is the action of the foot properly so called: the reach forward the action of the leg: and therefore seeing ambulation is made by station and motion, that is, standing and proceeding, the foot it selfe is the instrument of the former, and the whole leg of the latter.

The Office of the Foote.

How ambulation is made.

Now for assured and constant or firme station, as also for the accomplishment of those many motions wherof we stand in need, the structure & figure of the foot and leg is such as we see. For it is diuided into diuers ioynts, and the toes are made long and broad not so long as in the hands, but only as was necessary to fasten the feet when we would strue to run. For if the toes be pressed vnto the ground, it is strange with how much strength and security the body is driven forward.

The figure of the Foote.

The likenesse
betwixt the
Feet and the
Hands.

Moreover, the feete were made hollow in the midst that they might better passe thorough all places: for the hollow soale encompasseth that which is round or gibbous whereon wee tread, and the Toes do hold vs fast in right, oblique, sloping and ascending progressions. There is a great similitude betwixt the feete and the hands, so as we haue seene some who had no hands to do all the offices of the hands with the feete.

CHAP. XI.

The similar parts of the Foot in the large acception.

The similar
parts of the
foote.
The veines of
the foote.

LI that by the Ancients is called the Foote which reacheth from the hip joint euen to the end of the toes: It may be diuided into similar and dissimilar parts. The similar parts as in the hand so here are contayning or contained; contayning, as the scarfe-skin, the true skin, the fat & the fleshy membrane. The parts contained are the vessels, the flesh and the bones. The vessels are of three sorts, veines, arteries, and sinews. The veines doe all deriue their pedegree from the Crurall branch. This crurall branch shooteth out of himselfe many sprays through the thigh, the leg and the feet, deuided into many twigs. Six of them are among the rest most conspicuous & are called by these names: *Saphena*, *Ischias minor*, *Muscula*, *Poplitea*, *Suralis*, and *Ischia maior*. The *Saphena* or ankle veine arising from the kernels in the groine passeth down on the inside of the thigh betwixt the skin and the fleshy membrane, and reacheth over to the outward ankle and is after diuersly consumed or spent into the skin of the top of the foot. The lesser *Ischias* opposite to the *Saphena* is distributed into the fore skinne of the hip and the muscles of that part. The *Muscula* is diuided into two branches the lesse of which watereth the muscles which extend or stretch forth the legs. The greater lies deep in the flesh, and is diuersified almost into all the muscles of the thigh.

Saphena.

The lesser
Ischias.
Muscula.

The Poplitea.

The *Poplitea* is made of two branches of the crurall veine ioyning together, and after it hath sent some small sciencies into the back skin of the thigh it falleth down through the middest of the leg, and is sometimes spent into the skin of the calfe, sometime it passeth to the very heele, and sometime turneth aside into the outward ankle.

The Sural.

The *Sural* veine is disseminated into the muscles of the *Sura* or calfe, and vnto the skinne which is on the inside of the leg: and being reflected about the inner ankle, it attaineth vnto the inside of the foot and the skinne of the great toe, very rarely to any of the other toes. The greater *Ischias* hath two parts, one greater which passing through the muscles of the calfe spendeth it selfe into ten shoots allowing two to each toe. The lesser which endeth betwixt the Perone and the heele sometimes perforating the ligament in the middest, is dispersed into the muscle which draweth the toe backward and into the skin. The crurall artery brancheth it selfe like the veine, so that euery veine hath an artery accompanying it. The nerves which are disseminated through the whole leg are foure and those very notable, which arise from the three lower paires of the loynes, and from the foure vpper of the holy or great bone. The first and the vppermost falling vnder the *Peritoneum* to the little Trochanter is consumed into the muscles of the thigh, and into the skin, both on the out and the inside, before it touch the knee. The second and the lower, descendeth through the leske together with the crurall veine and artery into the thigh, and sendeth a notable branch to accompany the ankle veine through the inside of the thigh, euen vnto the foot, in the meane time bestowing smal tendrills vnto the neighbor skin, but the greater part of it together with the veine and artery is dispersed into the inner muscles of the thigh. The third lower then the former disperseth his fauors to the muscles of the yard, and to some of the muscles also of the thigh, not forgetting the skin of the leske, and afterward it determineth in the neighbour muscles about the middle of the thigh. The fourth which is the thickest, driest and strongest of all the nerves hauing his originall from the fowre vpper spondels of the *Os sacrum* or the holy bone, gliding along betwixt it and the hanche bone, affordeth certaine branches vnto the neighbor parts, as vnto the skin of the buttocks and of the thighe, and to the muscles contained vnder them. Afterward departing into two branches, the lesser falleth by the *Perone* and giueth two shoots vnto each toe, the greater reaching along the leg and the foote, giueth likewise two branches to each toe, but both these boughs by the way as they passe doe touch at the heads of the muscles and at the skin of the leg, and the foote, and doe tye them together. And this shall serue for a short description of the vessels.

The arteries
of the foote.
The 4. nerves
of the whole
foote.

The

The muscles of the foot are diuers: some Bend the thigh, Extend it, Bring it to the Body, lead it from the Body and turne it about: others do moue the leg with the selfe same kinds of motions, others bend and extend the foot it selfe. Finally, there are others, which moue the toes of the feete, the particular history of all which you may require in the next Booke of the muscles. The bones of the feete are very many: one of the thigh, 2 of the leg, called *perone* and *tibia*, together with the whirle bone of the Knee: the wrest of the feete called *pedium* hath 7. bones: the after-wrest called *Metapedium* hath 5, and there be 14 of the Toes, to which may be added seed-bones like to those which we found in the hand. Of all which we will giue you satisfaction in our Book of the Bones.

The muscles of
the feete.
The bones of
the feete.

CHAP. X.

An expliation of the dissimilar parts of the whole Foot.

The great foot is diuided as the hand into three dissimilar parts, the *Femur* or thigh, the *Tibia* or leg, and the *Pes* or foot. The Thigh is called *Femur a ferendo*, because the creature is therewith sustained or held vp. The fleshy parts are cald by *Hippoc.* *αἰχμή*, the fore-parts *καρπία*. The Pulpy or fleshy part about the ioynt below is (on the backside into which the Knee is bent) called *Poples* the Ham, because it is folded *post*, that is, backward: the fore-part is called *Genu*, that is, the Knee. The second part of the foote from the Knee to the Heele is called *κνήμη* or *σκέλος*, in Latin *Tibia*, we call it the leg: the fore-part whereof *Antitibiale* the Shin, the hinder and fleshy part *Sura* the calfe: the two processe without flesh neere the bottome *Malleoli* or the Ancles. The last part of the foot is called *pes parvus* and properly the Foot, because it is the Basis or pedestal wherupon the whole body resteth & it is the true organ or Instrument of progression: and as the hand is diuided into 3 parts, the Wrist, the After-wrist and the Toes. The Wrist is called *pedium*, and consisteth of 7. bones, 4 of which haue proper names, the other 3 none. The forepart of this *pedium* is called the in-step. The backpart is round and is called *Calx* or the Heele, the lower part of it is called *Calcaneum*, because with it wee do *calcere Terram* tread vpon the Earth, and we call it the pitch of the Heele.

The parts of
the foot in the
large accepta-
tion.

The second part of the Foot consisteth of 5 bones and answereth to the After-wrist of the hand, in Latin it is called *Tarsus*, the lower part of it is called the plant or the sole of the foot, the vpper part betwixt the Instep and the Toes is called *pectus* or *dorsum pedis* the brest or back of the foot. Finally the toes are 5 answering to the fingers of the Hand, and haue their owne orders, making 3 ranks called *συντάξεις*, excepting the great toe. These bones are ioy-
ned by *Ginglymos*, and haue seed-bones for their firmer articulation: for these small bones make the Foote stronger when wee stand still or walke on; especially if our way bee through sharpe places, where otherwise the Toes might easily bee luxed if they could be turned backe with stones or any other higher or vnequall substance whereupon wee should tread.

The use of the
seed-bones in
the foote.

And this is the true and succinct description of the Ioynts, wherewith wee desire the Reader to rest contented at this time, because he shall finde a more accurate delineation of all the parts of them in their seuerall places in the Tractes following, beginning with the most compounded parts, and so proceeding till we come vnto the the most Simple and

Similar.

The end of the Ninth Booke of the Ioynts.

Of Flesh, that is, of the Muscles, the Bowels and the Glandules.

THE TENTH BOOKE.

The Preface.

AS our ability, time and auocations have giuen vs leave, wee haue gone through our first diuision of the body of Man into the three Regions, Naturall, Vitall and Animal and the Ioynts. It remayneth now that we dissolue euery one of these into those parts whereof they are compounded, laying each apart by themselves that their Natures and differences may better appeare. In this *Analysis* or Resolution wee will first begin with the *Flesh*, which beside that it maketh the greatest part of the bulk of the Body, is also somewhat more compounded then the rest of the Similar parts. Next we will entreat of the Vessels, that is to say, of the Veines, Arteries and Sinewes; for these are the Riuer or Brookes which conuay the Blood, the Spirit, the Heat, the Life, the Motion and the Sense, into all the parts and corners of this Little world. Afterward we wil descend vnto the gristles, ligaments, membranes and Fibres: Parts, not onely Spermatieall and Similar, but also Simple, that is, not Organieall. Last of all we will come vnto the Bones, that is, to the foundation of this goodly Structure; the Pedestall or Columns vpon which the frame of the Body of Man is reared and whereby it is strengthened and supported. I know well that some Anatomists of the best note, haue in their deliuey of this Art quite inuerted this order which we haue proposed vnto our selues, beginning first with the Bones, and so ascending by the Gristles, Ligaments, Membranes, Vessels and Flesh, vnto the three Regions and the Ioynts: which Methode being *Geneticall*, wee conceyue to be rather the way of Nature then of Art; for Nature first lineth out of the masse of Seed, the warp of the body, and after with the woofe filleth vp the empty distances: first she layeth the foundation, raiseth the stories, bindeth the ioynts and plastereth the walles, till it come vnto a perfect building. Art on the contrary takes it asunder peece and peece, proceeding from that which is more to that which is lesse compounded, till at length it come vnto the very ground-woke or foundation. This Method we haue followed till we are come vnto the Flesh: Of which there are three kinde; one of the Muscles, another of the Bowels, and the third of the Glandules.

To the declaration of these three we haue destined this Booke, but begin with the Muscles, because they are more compounded then the rest.

CHAP. I.

What Flesh is, and how many sorts of Flesh there be.

Flesh in Latine *Caro*, in Greeke *σάρξ*, hath diuers acceptions amongst the Ancients.

Sometime in a strict and proper acception it is taken for the flesh of a muscle, as if a muscle and flesh were both one thing: so Hippocrates vnderstandeth it in the 16

The diuers acceptions of Flesh.

Aphorisme of the 5. Sect. where he saith, *That bathes of hot water will loosen the Flesh*, that is, dissolve the strength of a muscle: and in the 2. Section of his Book *de Fracturis* he calleth the muscles absolutely flesh, because their chiefe part is flesh. But most plainly of all in his Book *de Arte*, where he saith, *All those members which are compassed about with flesh, which flesh they call a muscle, all those parts I say, haue bellies*.

Flesh and a muscle all one.

Sometime by flesh we vnderstand that simple part which is peculiar and proper to each part of a mans body, and compasseth, gathereth together, & couereth the *Stamina* or fibres defending them against the rage of the naturall heate, which would consume and depopulate their very substance, as also against the heate and cold, and other outward occurrents.

The particular flesh of euery part.

Concerning this flesh Hippocrates in his Book *de Ossium Natura* hath this saying, *The Flesh is that which tyeth together and buildeth or reareth up all the parts of this frame*. We out of Galen and the late Writers do take knowledge of 4. distinct differences of flesh; one is flesh properly so called, another is the flesh of the bowelles, the 3. is the peculiar flesh of euery part, and the 4. the flesh of the Glandules or Kernels. The flesh properly so called is a soft and ruddy part made of blood moderately dried, and is therefore called a bloody part and a hot part: such is the flesh of the muscles, which is truly and absolutely called flesh, such is also the flesh of the Gums and that in the nut of the yard.

4. kinds of Flesh.

What is Flesh properly so called.

The flesh of the bowels *Erasistratus* calleth *parenchyma*, as it were an affusion or gathering together of blood. For hee thought that the substance of the bowels did accrue or gather of blood yssuing out of the veines. But wee thinke that the bowels haue a proper substance of their owne which is the principall and chiefe part of the bowell to which his action doth properly belong. There is also another flesh peculiar vnto euery solide part, which flesh hath no proper name, but Galen calleth it *Carnosam substantiam*, the fleshy substance: for in the 10. book of his Method he acknowledgeth a double substance in the solide parts, the one exquisitely solide and fibrous altogether without blood, another with stuffeth the fibres & filleth vp their distances, and is called the proper flesh of euery part, this he thinketh is neuer restored if it be lost but onely moystned and cherished when it is present. Such is the flesh which is to be seene in the stomach, the guts, the gullet, the bladders and the wombe. And such a kinde of flesh, *Theophrastus* attributeth vnto plants growing about their woody, and as it were sinnowy fibres.

The Flesh of the solide parts.

A two fold substance of the solide parts.

The common vses of this three-fold flesh Galen hath described in his 12. Booke *de vsu partium*, to wit, that it should defend the parts from heat and cold and other outward occurrences. For al flesh is a soft pillow for the creature when it eyther lyeth or falleth down; when it is wounded it yeldeth to the hardnesse of the weapon; when it is bruised or beaten it filleth vp the breach as it were a boulder of Lint: in the sweltering heat of the Sunne it serueth for a shadow, and in the violence of cold it keepeth warme. And these vses I haue called *Common*, because there are other peculiar to each kind of flesh: for the flesh of the muscles both moueth voluntarily and also by his stuffing it hindreth the chord or tendon of the muscles, least when it is contracted or drawne together it should depart from the body, as also it easeth and moystneth the drowth of the nerues and ligaments, which they continually acquire by their perpetual motion.

The common vses of Flesh.

The particular vses of the flesh

The flesh of the bowels as it were a certaine stuffing or concretion, i. confirmeth the vessels of the bowels, next it filleth vp the empty places betwixt the vessels; and lastly it performeth a similar and official action as we shall say anon. Finally there is a glandulous flesh, such is the Pancreas a kernelly body placed in the belly neere to the gate of the liuer: for some haue defined a glandule to be a masse of flesh rowled vp in it selfe. And these in my iudgement are all the differences and distinctions of flesh. The particular history whereof, we will as accurately and briefly as we may describe vnto you in this following discourse, beginning with the flesh of the muscles, as being a more compound and organically part, and so proceeding to the bowels and glandules, which are more simple and similar, originally deriued from the first conformation of the body.

The Flesh of the Glandules.

The order of this Booke.

CHAP.

CHAP. II.

Of the Flesh of the Muscles, and what a Muscle is.

THe first and chiefe kind of flesh, is that of the Muscles, in the description whereof because of the variety and difficulty of the subiect, we must craue a little leaue somewhat to enlarge our selues. For it is far and wide spread over the whole body, and maketh indeed the greater part thereof. This is that which giueth strength, proportion, and beauty to all the other parts, whereof if the body be dispoyled, as it happeneth in the melting and dissolving heate of a hecticke ague, there remaineth nothing else but the image of a dead creature, nay of a dried and parched carcasse: which may seeme to be the reason that moued Hippocrates to call his Book wherein he treateth of the principles of the body and the nature of the particular parts (a work which he composed in his old age, as appeareth by the experienced certainty, maiesty and weight of the sentences therein contained) *de carnibus* a Book of flesh. The flesh therefore when it is gathered together on a heape Hippocrates calleth a Muscle in his Book *de Arte* as we haue said before, and againe the muscles hee calleth absolutely Flesh, because the principall part of them is the flesh. And in his prognosticks from the laudable and commendable habit or proportion of this musculous flesh, he gathereth the perfect health of the whole body. And in the 4. section of his Aphorismes and the 16, when he would describe a haile body, he maketh mention only of this flesh, where he saith, *Ellebor is dangerous to such as haue sound flesh*, that is, such as are in perfect health. For the muscles are a kind of part both governing and being governed: they gouerne those members for whose motion they were ordained, and are governed by the Braine through the nerues, by the Heart through the arteries, and by the Liuer through the veines: wherefore if these be in good plight (which is easy to be knowen by the naturall figure, fresh and flowry colour, and their iust and due extent) they show that the principall parts are in a good and commendable constitution. The nature therefore, differences and actions of these muscles wee haue taken for our present taske; wherein how fairely fouer we shall acquite our selues, yet wee make account as in all other parts of this labour, so especially herein, by reason of the difficulty to finde the truth and diuersity of mens opinions; we shall expose our selues to manifold censure and exception, vnlesse wee light vpon the more equall Auditors. But to the matter.

A Muscle is called in Greek *μῦς*, that is, a *Mouſe*, eyther because it is like vnto a fleine Mouſe, or vnto the Fish which they cal *Musculus*. It hath also diuers Latin names, one from the Greek, which is *Musculus*, and that we will incorporate or infranchise into our English, although the next Latin name, which is *Lacertus*, in English a Brawne, might reasonably well be retained, had not vs made this other more common. For we call an Arme full of sound flesh, a *brawny Arme*: but to hold the name of Muscle. There is a double consideration to be had of a muscle; the first is, of the structure or composition of it, the other of the office and vse: and therefore there may be a double definition giuen of it.

If you regard the structure, it is defined by Galen in *Arte parua*, *A flesh wouen of simple flesh and similar fibres*. And in the Book of Physicall definitions it is called *A sinowey body mingled with flesh*. It may more fully be defined thus: *It is an organicall and dissimilar part wrought together of Nerues, Flesh, Fibres, Veines and Arteries, all covered or inuested with a proper coate of his owne*.

That it is Organicall, Galen teacheth in his Book *de differentijs morborum*, in which place he reckoneth it among those Organs which are most simple and of the first kind, because it is not made of dissimilar particles but of simple.

That it is Dissimilar, the structure or the parts being of diuers kinds do evidently proue. The nerues are the conuayers of the spirits & the faculties; the flesh stuffeth the distances between the fibres that they should not be mingled, tempereth the drynes of the nerues and tendons, preferueth the threds or fibres that they be not bruised or broken, and maketh the Animall spirits more apt to moue by his heat. The Fibres which are wouen of small particles of the ligaments diuersly disheued do strengthen the flesh, establish and preferue it that it be not dissolved; the veines like small riuers, are provided only for nutrition; the Arteries do conserue the heat; the coate inuesteth the muscle, containeth his substance, separateth & distinguisheth it from the adioyning parts and giueth it the sence of feeling. This is the structure of a muscle, according to them all, to them alone and at all times.

There

There is another definition of a Muscle taken from his office which *Galen* delivereth in his first Booke *de motu musculorum*. A muscle, saith he, is the instrument of that motion which is performed with violence, or a Muscle is the immediate organ of voluntary motion. By violence *Galen* understandeth that which *Aristotle* calleth *Spontanum*, or voluntary which proceedeth from an inward principle, to wit, from a desiring or moving faculty. *Galen* calleth that which is Voluntary often times Animal to distinguish it from that which is Naturall: and in his Booke *de tremor: palp.* he calleth Muscles Organs which are moved at our discretion.

The explication of the definition.

Now that motion is Voluntary which at pleasure we can appease, and againe excite or stirre vp when it is appeased, and make it swifter or slower, rarer or quicker as we list.

What is voluntary motion. A double will from election and from instinct.

This will or pleasure of man is double; one from Election, another from Instinct: the first wee exercise when wee are awake, the latter when we are asleepe or minde some other matter more. The first is a stretching or Tention not without strife or contention, the second is in remission or rather the remission it selfe of that contention or strife; and therefore they that are asleepe do neyther moue their bodies into extreame and violent figures or postures, neither doe they accomplish the perfect *Tonicall* motion, that is, the stedfast holding of the member, as those that are awake.

Of this Voluntary motion there are diuers instruments, the Braine, a Sinew and a Muscle, but one is immediate. The Braine commandeth, the Sinew or Nerue carrieth the commandement, and the Muscle obeyeth. The Braine determineth of the object which is to be desired, whether it be profitable or noxious and hurtfull, to be followed or avoided: from hence therefore is the beginning and originall of the motion. When the action is agreed vpon by the Braine, the Nerue which is the spirits vehicle carrieth downe the faculty of moving: the Muscle being illustrated or enlightened with the beames of the spirit is presently contracted and immediately moueth the part according to the diuersity of the commandement which it receiueh from the will. And as a horseman hauing the reynes in his hand dryueth forward or reyneth in the horse, so the fantastick power of the Soule sitting in the Braine, by the nerues as by a reyne or brydle moueth the muscles.

Three organs of motion.

How these 3 do worke.

An apt comparison from a man on horsebacke.

These things therefore are necessarily required to locall and voluntary motion, which in order doe follow one another. An object appetible or to be desired, The faculty desiring, and a power to moue locally The Braine, the Animall spirits, the Nerues and the Muscles.

We conclude therefore that a muscle is the immediate instrument of voluntary or willing motion, whatsoever can be objected against the truth of this definition should haue receiued satisfaction in our discourse of the Controversies belonging to this Booke; but the volume groweth already so great that wee are constrained to forbeare the annexing of them in the three last books.

CHAP. III.

How many and what are the parts of a Muscle.

THe parts of a Muscle we wil distinguish into similar of which the whole body of the Muscle is composed; and dissimilar into which the same body according to his length is deuided.

The parts of a muscle.

The similar parts are Nerues, Fibres, Tendons or Chords, Flesh, Veines and Arteries. The dissimilar are three, the beginning, the middle, and the end; or the *Head*, the *Belly*, & the *Taile*. Out of these similar parts ioyned together and diuersly intangled with an admirable arte, resulteth an organ ordained for voluntary motion. But in this composition there is not the like worth or vse of al the particles, neither doe they meet together in the same degree or efficacy of operation.

Wherefore as before in euery perfect organ we obserued foure kinds of parts; the first of those by which the action is made originally and essentially; and to these *Galen* attributeth the preheminance or superiority: the second of those without which the action goeth not forward; the third by which it is better performed; the last of those which doe conserue the action or keepe it (as we say) in tune: so all these foure differences of parts a diligent Anatomist may obserue in a muscle. The fibrous flesh is the prime and principall part of a muscle, and as *Hippocrates* and *Galen* doe beleue the proper substance of the same: for if you reuiew the whole body you shall finde none like it; when that is wanting or decayed the motion also is weake or none at all, and where it is there also is alwayes voluntary motion: this

In all organs 4 kinds of parts are to be obserued.

The flesh is the principall part of the muscle.

this only is prepared and fitted by Nature to receive the influence of the *moving quality*: this alone doth easily collect, contract and gather vp it selfe together, and looseth and remitteth the part which it hath drawne: so also the chiefe part of all the bowels is said to be their flesh or *parenchyma*.

The Nerues which are diuersly dispersed into the muscles, are those without which the motion cannot bee: for they are the conuayers of the Animall spirits, and bring down from the throne or tribunall of the Soule, which is the Braine, the warrant & commandement to moue: if they be cut, obstructed, refrigerated, inflamed, or any other way affected, the motion perisheth instantly. The Ligaments and Tendons do make the action more perfect; for the tendon is not as we say in Schooles *simpliciter*, that is, originally and by it selfe ordayned for motion, but *secundum quid*, that is, for the performance only of vehement, strong and continuall motions, and therefore there be very many muscles without tendons.

The Veines, the Arteries, and the Membranes, are they which conserue the action, for the veines and arteries do restore the wasting and decaying substance of the muscles, which by reason of continuall expence are washy and fleeting: and therefore they are in great abundance dispersed through the flesh, because as *Hippocrates* saith *Flesh is a drawer*, and the blood ought to be in greater quantity then the rest of the humors because the maintenance of the muscle ariseth thereby. The membrane as it were a garment or couering inuesteth and closeth the muscle and giueth it the sence of feeling. And thus much concerning the nature of the similar parts of which the muscle is formed.

Now the whole body of the muscle is diuided into three dissimilar parts, the *Head*, the *Belly* and the *Taile*.

The Head is most commonly neruous, sometimes but rarely fleshy: for it is made of ligaments arising from the bone, yet it is not altogether insensible because of the insertion and interposition of the sinews, for it is couered with a peculiar membrane.

The Belly is the middle part of the muscle almost all fleshy, & maketh the bulke of the same: and for that reason in the leg they call the pulpe, that is, the brawne of the Calf wherein the middest of all the muscles of that part doe so meete that they seeme to make but one muscle, they call it I say *γαστρονύμιον* as it were *the belly of the Leg*, we call it the Calf.

The last part of the muscle is the End, the Taile or the Tendon, it is called *ἀκρονύμιον*, because it is almost altogether neruous. *Galen* thinketh that the Tendon is framed of the fibres of the nerues and ligaments confounded and mingled together, yet so that there are more fibres or strings of the Ligaments then of the Nerues, whence it is that the tendon is sixe yea ten fould thicker then a nerue.

And the reason of this mixture is because the ligament of it selfe and his owne nature immouable and insensible, could not alone performe a voluntary motion: and againe the nerue because of this softnes and flight or thin texture was not able to draw the vast bulke or magnitude of the members: and therefore it behoued to make of them both a mixt organ which should be harder and stiffer then the nerue for strength, and softer and more pliable then the ligament for motion: & such is a tendon partaking of the nature of them both, so becoming of a middle disposition betweene them; more sensible and weaker then a ligament, stronger and lesse sensible then a nerue.

Furthermore, we must remember that all muscles haue not tendons or chords, as the muscles of the Tongue, the Testicles, the Lips, the Fore-head, the Yard and the 2. Sphincters: but only those which are moued eyther strongly, or vehemently, or continually. Those that are ordained for the motion of bones, do alwayes end and determine into tendons eyther greater or lesse, and are inserted not into the iuncture or very ioynt of the bones, nor into the ends of that bone from which they arise, but for the most part into the head of the bone which is to be moued wrapping it about. The muscles also which moue continually though their motion be neyther strong nor vehement, yet they stand in need of a tendon: and therefore the muscles of the eyes are not without them.

The tendons make the action more perfect.

Hippocrates.

3. dissimilar parts of a muscle.

The Head.

The Belly.

The Taile.

Whereof the tendon is made.

The reason of the composition.

Why the small muscles of the eyes haue tendons.

CHAP. IIII.

what is the action of a Muscle, and the differences of the motions thereof.

 Muscle as it is an Animall Organ hath one and but one action, to wit, Motion: the Nature of which motion is not obuius or easily knowne of all. *Galen* in the 8. chap. of his 1. Booke *de motu musculorum* acknowledgeth foure differences of motions in these words: *The muscles are eyther contracted or extended, or sinke of themselves, or else remaine streatched or distended.*

There are 4. motions of the muscles.

Contraction is the proper and ingenit action of the muscle; for whilst it moueth any part whether it houldeth it stedfast when it is bent, or bendeth it being before stretched or distended, it is alwayes contracted or drawne vnto his owne originall, that is, towards his head. Now that contraction is the proper action of euery muscle, hence it appeareth that if the muscle be cut atwo in the middest ouerthwart his body, you shall see the one part contracted vpward and the other part contracted downward.

The 2. motion of the muscle is extention, which is not proper but aduentitious or accidental: for when the contracted muscle is extended it is loosened by another and not by it selfe: and therefore almost euery muscle hath ioyned vnto him a companion, nay rather an *Emulus concurrent* or aduersary, because it is the author of a motion contrary to his: As for example, euery flexor or bending muscle hath a tensor or extending muscle; euery adductor, that is, which moueth toward hath an abductor which moueth forward; euery leuator or lifting muscle hath a depressor or sinking muscle. When as therefore a muscle which is contracted is also extended, in this extention it followeth the motion of his *Antagonist* (for so we vse to call them) or aduersary, so that the extention is not the proper motion of the muscle that was contracted, but rather his passion then his action.

Extention the 2. motion of the muscle.

Note this.

There is a third motion of a muscle which is yet more improper, in which it is neither contracted nor relaxed but falleth with his owne weight, and this is called *translation* or *decidence* and sinking: this motion is not from the Soule but from the elementary forme, for the part not illustrated with the beames of the animall spirit falleth with his owne weight, and so the part is moued with the mouing faculty being at rest. So *Galen* saith that the tremor or trebling, which the common people call the shaking Palsey, commeth to passe by an equall contention or strife between the mouing faculty and the moued member, for the faculty listeth the member vp, and the waight of the member sinketh it selfe again, and so from that vicissitude or interchange of lifting vp and falling down commeth the trembling.

How trembling commeth

The last motion of the muscles we call *tonical*, wherein the fibres of the muscles are stretched and so remaine; so that the part seemeth indeed to be immouable but yet in truth is really moued. This motion is most euident in Birds when they fly or glide in the ayre with their wings stiffe stretched and seeming immouable; which motion *Virgill* expresseth excellently in the flying of a doue where he saith,

The last motion which is Tonicall.

Radit iter liquidum, celeres neque commouet alas.

A man also standeth by this motion, and so a Pisimre moueth vpward vpon a staffe as fast as the staffe descendeth downward.

Examples of Tonicall motion.

Of this motion *Galen* speaketh when he saith, that euen in sleep the muscles do moue. There are therefore in all 4. motions of the muscles, 2. performed by themselves, and those are contraction and the conseruation of that which is contracted which second motion is that we call *Tonicall*: for such is the Nature of successiue or succeeding motions, that they are no lesse accomplished when they are conserued then when they are first made.

2. motions per se.

The two other contrary to the former are by accident, to wit, Extention and Decidence; Contraction, Extention and the tonical motion haue sometimes extream sometimes middle figures or postures. All extream positions are painefull, those that are meane are easy or pleasant: the extream we cannot long endure vnlesse we bend our mind and power vnto it: the meane we easily endure when we thinke not of it. And therefore whilst we sleepe we very rarely suffer any extream flexions or extensions of the muscles, and then only when the fancy worketh exceeding strongly: otherwise the muscles are inclined rather then bent to eyther side, as *Hippocrates* obserueth in *Prognostico*: They lie (saith he) when they sleep with their Thighes, Hands, and Feete moderately reflected or inclined, because at that time the strength of the Animall actions is not ceased but only abated.

2. other per accidens.

Men

What the figure of the muscle is when it worketh & when it plaish

Men also in their sleepe haue not so strong Tonnical motions as when they are awake, as we may perceyue in the sphincter muscles which shut vp the wayes of the excrements, which performe indeed their Tonnical motion in a good sound sleepe, but if the violence of the excrement be great they either cease their motion and so the excrement auoydeth, or else the faculty being distressed calleth for more helpe, and so the party awaketh and becommeth more able to hold his owne. But it is worthy obseruation that all muscles when they moue are crooked, and when they rest are stretcht: and the reason is, because being contracted they become broader and shorter, and longer when they are relaxed: but from this generall rule, the muscles of the *Abdomen* and the *Intercostal* muscles or those betweene the ribbes are to be excepted, for when they are relaxed and the contention remitted they grow crooked, which I thinke happeneth by reason of the laxe and yeelding emptinesse of the chest and the lower belly.

CHAP. V.

Wherein all the differences of Muscles are shewne.

All the difference of muscles.
The first.

He Muscles do differ among themselves in their substance, quantity, figure, site, originall, insertion, fibres, parts, vse, and action. If you consider the substance, some are fleshy all ouer as the sphincters and muscles of the tongue: others are almost all nervous or membranous, as that *abductor* or forward muscle of the leg which is called *Membranous* or *fascia lata*, the broad Rowler.

The second.

The quantity considereth the dimensions; now dimension is threefold. Length, and hence some Muscles are long, as the right muscles of the *Abdomen* and the *Abductor* of the Leg, and some short. Breadth, and hence some are broad as the oblique and transuerse muscles of the *abdomen*, and the broad muscle which beareth down the arme, and others narrow: the last dimension is altitude whence some are thick, as the two large muscles called *Vasti*, and some are thinne or slender, so much for the quantity.

The third.

The figures of the muscles are manifold, some like a Mouse, some like a Snake, some like a Plaice. Again, some are triangles, some quadrangles, some five cornerd, some pyramidall or spiry, and some orbicular or round. To this kinde we may referre the Muscles called *Deltoides*, *Rhomboides*, *Scalenus*, *Trapezius* and such like.

The fourth.

From the situation, the diuision or difference of Muscles is very elegant: this site we consider in the position of the fibres and in the differences of place: from the position or tract of the fibres some muscles are right, some oblique and some transuerse. The oblique are most fit for oblique or side motions, the right for more exact flexion or extention.

The differences of the place according to the length doe make the muscles higher or lower: according to the breadth, right and left: according to the height, forward, backward, internal and external. Those occupy the inside which bend the part, and those the outside which doe extend it: and so much for the site.

The fifth.

In respect of the originall some arise from Bones, and these now from their heads or extuberations when they behoued to be greater; now a little lower or from the cauities, sometimes from one bone, sometimes from more; others from gristles, as the proper muscles of the *larynx* or throtle; others from a membrane incompassing the tendons or chords, as those which are called *Vermiculares* or the wormy muscles; others from other parts, as the sphincters.

The sixth.

The difference from the insertion is, that some are inserted into a bone, some into a gristle, as those of the throtle and the eie-lids; others into a membrane, as those which moue the eye; others into the skin, as those of the lips; others into other bodies: some also there are which hauing distinct originals do yet end and determine into one part: and some againe hauing but one originall are inserted into diuers parts. And so much of the insertion.

The seventh.

Now if you marke the texture of the fibres, they are of one kinde almost in all muscles: and yet there want not some which haue two or three kind of fibres manifestly appearing in them, as that which is called *Pectoralis* and *Trapezius*, as also the muscles of the lippes, from whence come their diuers and different motions.

The eighth.

The eighth difference of Muscles, is from the diuersity of their parts; now by parts in this place I meane both the especiall parts of the Muscle it selfe, and those parts or places wherein such muscles are seated. The parts of the Muscles are three as wee haue sayd, the Head

Head the Belly and the Tayle. Most Muscles haue but one Head, some two, and some three, from whence they are called *Bicipites* and *Tricipites*. The Belly sometimes is one and sometimes two as in the Muscle which shutteth the lower Iaw and that of the bone *Hyais* which is at the roote of the Tongue, which Muscles from their double bellies are called *Digastrick*. The Tendon is in some broad and membranous, in others round, in some short, in others long, in some perforated; in others there is none at all, in others but one, and in others many Tendons: sometimes also you shall perceiue diuers Muscles to determine in one Tendon, as in the leg of the *Twins* and the *Soale* is made one Chord or Tendon.

From the parts in which the Muscles are seated they haue also names to distinguish them from others, as *Crotaphita* or temporall Muscles, *Rachia* or *Spinati*, that is, *Thorny* Muscles, and *Iliaci*, that is, Muscles of the *Ilia* or *Flankes*. Finally the most necessary difference of Muscles, as I thinke, is taken from their vse and action. The action of the muscle is voluntary motion: therefore according to the variety of their actions shall be the differences of the Muscles, which I am wont to referre to three especiall ones. The first shall be this. Muscles are eyther of a kindred, or of an aduerse faction. I call those a kin which do conspire & agree into one and the same worke, as the two *Flexors*, and the two *extensors*, the one of which vseth to occupy the right, the other the left side. Those of the aduerse faction are called *Antagonists* opposites or *Concurrents*, which performe actions contrary or succeeding one to another. For euery Muscle almost hath set vnto him another, whose action is contrary to his, as to a *flexor*, is set a *tensor*, to a *levator* is set a *depressor*, to an *adductor* is set an *abductor*; onely we must except the two *spinners*, and the *Cremasters* or hanging Muscles.

Those that are a kin are almost alwayes alike in magnitude number and strength, but the opposites are not alwayes so equall, but vary much according to the weight of the part which is to be mooued, or the vehemency of the action. So they are but two which bow the head, but to stretch it out and lift it vp there are twelue. Againe, there are many which close the neather Iaw, and but onely two that open it: for heauy things or parts do easily fall with their owne weight.

Of these Muscles which are of a kin *Galen* hath left this rule. *As often as those muscles which are of a kinne are in opposite parts equall in number, magnitude and strength, the resolution of one makes the conuulsion of the other.* And of the opposites or *Antagonists* he writeth thus in his first Booke *de motu Musculorum*. *Of those motions that succeed one another if one perish the other must needs be taken away. For if that which extendeth be cut a sunder, the part indeed shall be contracted or bent, but it shall alwayes so remaine because the muscle that should extend is cut a sunder.*

The second difference of Muscles taken from the variety of their motion or action shall be this. Some Muscles moue themselves, others other bodies. They which moue themselves are *spinners* of the fundament and the bladder: they which moue another body beside their owne moue a bone, or some other thing then a bone. Those which moue a bone doe end in Tendons either greater or lesse: they which moue another thing beside a bone, some of them haue Tendons, and some haue none. They which moue such parts as are easily moued haue none, because their motion is not vehement, as the Muscles of the Tongue and of the Testicles; but the Muscles of the Eyes haue Tendons, because being continently and perpetually mooued, though it be but a small part yet it needs a strong moouer.

The third difference of the Muscles taken from the variety of their actions respect to their peculiars motions which are diuers; from whence they are called *Flexores*, *Tensores*, *Attollentes*, *Deprimentes*, *Adductores*, *Abductores*, *Rotatores*, *Circumagentes*, *Masseteres*, *Cremasteres*, *Spinneres*. That is, *Benders*, *Stretchers*, *Heauers*, *Sinkers*, *Tow-ward*, *Fro-ward*, *Rowlers*, *Compassers*, *Mangers*, *Hangers* and *Binders*.

CHAP. VI.

Of the number of Muscles.

THe Authors of Anatomy haue not agreed vpon their verdict concerning the number of the Muscles, neither to say truth is the euidence so pregnant as to ingage a mans faith; some doe acknowledge more, and some fewer, some there are which looking with spectacles make many of one, and these increase the number, happily beyond the stint of Nature; some againe are so thicke figured that of many they make one.

The muscles
are 405:

A briefe enu-
meration of all
the particular
muscles.

Wee in this one Chapter will comprise the whole Forrest and confusion of Muscles into a briefe summe. *Silvius* hath given them almost all proper names, either from their action, vse, figure, or the similitude of some outward thing, which because they seeme to represent the matter with more life, and are beside a great helpe to memory, wee will retaine them in our History.

The Muscles therefore in the whole summe are foure hundred and five. First 2 of the forehead, 6 of the eye lids, on each side 3. two doe open them, and foure shut them. The Eye is rowled after a strange volubility by 12 Muscles, 6 in each eye, the *beauer*, the *sinker*, the *too ward*, the *fro-ward*, and 2 rowlers.

The outward Eare is moued by sixe, 3 the right and 3 the left: two dilate the Nostrils and 2 contract them. The Lips haue nine, 4 moue vpward and as many downward, and the ninth is called *Buccinator* or the *Puffer*, *Winder*, *Sounder* or *Trumpeter*. The lower Jaw hath tenn which moue it vpward, downward, forward, backward and on both sides. The bone of the Tongue called *Hyois* (if at least it may be called a bone) 8 muscles doe suspend and establish. The Tongue is moued like an Eele, vpward downward, forward backward and to the sides, by 10 muscles. The Chops haue eight, 4 on eyther side which helpe the swallowing. The *Larynx* or Throttle is dilated, constringed, opened and shut by 14. foure common and ten proper. The Head hath likewise 14: sixe greater and 8 small ones. The Necke hath eight, 4 to bend it and as many to extend it. The Shoulder-blade hath all his motions performed by 8 peculiar muscles, foure in each shoulder-blade, *Trapezius*, *Leuator Proprius*, *Serratus minor* & *Rhomboides*, that is, the Table, the proper Heauer, the lesser Saw and the Plaine. The Armes are each of them moued with 8. their names are *Deltoides*, *supra-spinatus*, *latissimus*, *rotundus maior*, *pectoralis*, *infra spinatus*, *rotundus minor* & *subscapularis*, that is, the halfe Lozenge or triangle; the Ridge blade or blade-ridge muscle, the broad muscle or Pruritane or claw backe, the great Bowle, the Pectorall, the Snaile, the lesser Bowle and the Lurker. The Cubit hath foure, in each 2 benders and 2 stretchers: the 2 benders are called *Biceps* & *Brachialis*: the 2 stretchers are called the *Long* and the *Short*. The *Radj* haue each of them foure, two fore-bowers, the *round* and the *square muscles*, and as many backe-bowers. The Wrist is bent by two, and extended by other two. The Fingers (excepting the thumbe) haue 3 benders, *Palmaris*, *Sublimis* and *Profundus*, the Palme muscle, the Floating muscle and the Deep muscle; and foure stretchers; 4 *too-ward* which are called *Permiculares* or the wormes, and 6 *fro-ward* called also *Interossei*, because they ly among the bones; in all 17. The thumbe hath nine, 1 bender, 2 stretchers, 3 *too-wards*, and as many *frowards*. There is also in the little finger a peculiar muscle which moueth it froward the rest, so that in each hand there are 27.

The Muscles seruing for Respiration are in all 65. of which 32. doe distend or dilate the Chest, and as many contract it. Valuable to all which for both vses is the odde Midriffe. As for those 11. internall and externall, which are fancied to be betweene the gristles of the ribs we doe not acknowledge them saith *Laurentius*. The *Abdomen* hath 10. muscles, 4 oblique, 2 right, 2 transuerse and 2 small or pyramidall muscles. The backe is moued by ten, 5 on each side. The Fundament hath foure, 2 *sphincters* and 2 *beavers*. The Bladder hath 1 *sphincter*. The Testicles haue 2 muscles called *Cremasteres* or hangers and suspendors. The Yarde hath 4. The Thighes are each of them bent by two called *Psoas* and *Iliacus*, and three stretchers, which are they that make the substance of the Buttocks, there also are *too-ward* muscles and 6 *froward*, 2 *obscurores*, and 4. twinnes called *quadrigemi*, wherefore the muscles of the thigh are in all 28.

The Legge hath foure benders called *postici* or the posterne muscles, and so many stretchers, the right, the 2 *Vast* and the *Cruriens*; two are *too-ward*, the *Long* and the *Ham* muscles, and 1 is *fro-ward* called *membranofus*, so that the muscles of the Legges are 22.

The Foote hath two that bend it, that is altogether in the in-step called *Tibialis anticus* and *Peroneus*, and 4 which stretch it, 2 twinnes *Soleus* and *Plantaris*.

The Toes haue 2 benders, *Sublimis* & *Profundus* and 2 stretchers, 4. *too-wards* called the *Wormes*, 8 *fro-wards* called *Interossei*. The great Toe hath 1 bender, 1 proper stretcher, 1 *too-ward* and another *fro-ward*. There is also one peculiar *fro-ward* muscle of the little Toe, so that in each foote there be 21. muscles for the moving of the Toes. The totall sum of all these in the whole body is 405. whether thou wilt add more or make these fewer, for my owne part saith *Laurentius* I do not greatly care, no more do we, but haste vnto our peculiar History of the Muscles of each part, beginning with those of the Head.

CHAP. VII.

Of the Muscles which moue the skin of the Head.

WE haue saide before that the skinne of the Head is moued according to our good pleasures, in some men all of it round about, but in most onely the skin of the forehead and the face. The Ancients, as *Galen* for example (in his 11. Booke *de usu partium* and the 15. Chapter) thought that this motion came from a thin and musculous substance which is subiected or lyeth vnder the skin of the forehead and is vnited thereto as the palmes of the hands and Soales of the foote are vnited with their Tendon. But the late writers with more euidence of truth by curious obseruation haue found out and allotted to euery part of the face his peculiar muscles, for we call all that the face that may bee seene outwardly. Some of these are in the forepart of the face as the forehead, the Eye-lids, and the nose: others in the backpart of the head called *occipitium*; some on both sides, as in the lips and the cheekes.

The skin of the forehead (which by his tension and corrugation, that is, smoothnesse or wrinkling demonstrateth the manifold affections of the mind) is moued not onely by the helpe of the fleshy membrane, growne more fleshy as *Vesalius* thought (and so being vnited to the flesh vnder it, passeth into a musculous substance furnished with right fibres) but also by two muscles, as appeareth both by the course of their fibres and by their motions; the fibres appeare in these after the manner of other muscles, and their motion is not like the motion of the fleshy membrane.

Fallopins also and *Platerus* haue given them names. *Fallopins* calleth them the first paire moouing the skin of the head, and *Platerus*, the muscles of the affections. These are seated in the forehead, and doe arise aboue where the haire determines sometime as high as the crowny seame neare the temporall muscles, the right at the right and the left at the left temple (where the fleshy membrane cleaueth so close to the scull-skin and the scull it selfe, that it is altogether immooueable, that the forehead and the eye brows might be mooued when their membrane is at rest) and toward the common seame which distinguisheth the bones of the head from those of the vpper iaw, are implanted with right fibres aboue the eyes and the nose into the skin at the brows, as at the parts which are to be moued: for when the brows are mooued they draw in a straight line together with them the skin of the forehead. I saide right fibres and not oblique as some haue thought, and therefore Chirurgions must obserue that in opening apostemations in that place, they make not their incisions ouerthwart as the wrinkles of the skin doe goe, but according to those right fibres.

Wee must also obserue that these two muscles are a little disioyned in the middest toward the top of the forehead, and that is the reason why the vpper part of the forehead is not mooued; but at the top of the nose (where also they become more fleshy) they are so ioyned that they seeme to be but one muscle. But that they are two, not onely Anatomie but also reason and experience do teach; reason, because Nature hath made all members double that the body might be equally ballanced: Experience, because we finde that if one of them bee eyther taken with the palsey or wounded ouerthwart, the affected side onely looseth his motion and not the other, whereas if there were but one, there should bee no motion at all. And *Columbus* maketh mention of a Cardinall whose left muscle suffering convulsion by reason of a wound he receiued aboue his brow, did notwithstanding moue the halfe of his forehead. Againe, when we are mooued to displeasure, wee contract and wrinkle the skinne in the middle of the forehead, so that the browes doe almost touch one another: which contraction of the skin could not be made if there were but one muscle.

The vse of these muscles is by the contraction of their fibres to lift vp the browes together with the skin of the forehead, and vpon their relaxation to settle them againe. For the forehead is mooued as *Galen* elegantly discourseth in his 11. Booke *de usu partium* and the 14. Chapter because of the eyes: for when the forehead is lifted vp the browes also fly vpward and the eyes are better opened to see more at once. And againe, when the eyes are shut for feare of any thing which should rush vpon them, they are better and more strongly closed by the falling of the browes and the forehead. The muscles which draw the skin of the head backward are two, on either side one, arising very slender from the transuerse line of the *occiput* or nowle of the head, into which line the second muscle of the shoulder-

head.

Aquapendens
his muscle of
the eye-brows

blade called *cucullaris* or the Cowledoth determine: from this line doe run fibres directly vpward and make these muscles, which are very short and not aboue an inch, but yet so broad that either of them toucheth the eare of his owne side, and they end into a thinne and broad Tendon, which seemeth to be made of the fleshy membrane, and occupyeth or compasseth the whole head and the fore-muscles of the eare, and ioyneth also together the muscles of the forehead. The vse of these two muscles is to draw the Skin of the Head backward; and therefore *Columbus* thought that they drew also the eye-brows and instanceth in the example of one *Iohannes Antonius Platus*, who could moue the whole skinn of his head very strongly as also could *Columbus* himselfe. But as the muscles of the forehead are neuer wanting, so these of the nowle and the fore-muscles of the eares (as *Falopius* and *Platerus* haue also obserued) are but seldome found.

Beside these *Aquapendens* ascribeth to the eye-brows a round muscle differing from the circular muscle of the eye-lids, because that of the browes hath thicker and more fleshy fibres, and beside is somewhat larger; drawing the brow especially downward to the eye, and being like vnto a Ring attracteth also the lower lid very strongly.

CHAP. VIII.

Of the Muscles of the Eye-lids.

Great differences among
Anatomists
concerning
these muscles.

That the Motions of the Eye-lids are and their necessities, as also of what kind Voluntary or Naturall with other circumstances thereto belonging, we haue declared before in their History. Now concerning the number of these muscles whereby these motions are effected, I finde great difference between *Galen* and the late Writers, and amongst the late writers themselves.

Galen and the ancients with whome *Vesalius* and *Sylvius* doe agree do make two, deuinding the orbicular muscle of which we shall treat anon into two: one lifting vp the Lid, the other bearing it downe. *Laurentius* is of the same mind for the diuision of this muscle but not for the Vse, for he thinketh that they both serue to shut the vpper Lid: so that it should seem that *Galen* & those that side with him did not know of any muscle which should open the eye. *Falopius*, *Platerus*, *Bauhine*, *Laurentius* and *Aquapendens* affirme, that for the opening of the eye there is but one muscle. *Columbus* and *Archangelus* say there are two; the first we admit, the second we say serueth to rowle the eye. But to passe by these contentions you shall giue me leaue to resoluue the matter thus.

The place of
the right muscle.

The motions of the Eye-lids are performed by two muscles, one right in the vpper Lid which listeth it vp, and the other round. The right muscle (which *Galen* knew not, neither *Vesalius* nor *Sylvius*, but *Falopius* challengeth the inuention of) which listeth vp the vpper Lid [tab. I. M] is seated within the concavity of the bones in the vpper part of the orbe aboue and neare the muscle which listeth vp the eye to which in figure it is very like, and fleshy but lesse, and ariseth backward at the in-let of the opticke nerue from the same originall with the other muscles which moue the eye, and being directly stretched to the vpper Lid is inserted with a broad tendon into his end or cartilage. His vse is by contracting his fibres inward to draw the vpper Lid vpward (for the lower ferleth into his place of his owne accord) and so vncovering the eye it openeth it.

The orbicular
or round muscle.
His position.

The semicircular or round Muscle [tab. I. K] is seated betwixt the fleshy membrane and that which is produced from the *Pericranium* or Scull-skin, and is membranous and very thinne or slender, yet a little increased by certaine circular and fleshy fibres which he borroweth from the fleshy membrane, and so standeth halfe round in either Lid.

His originall.

It ariseth with a sharpe beginning at the roote of the nose in the great and inward angle of the lower Lid where the common future is betweene the head and the vpper iaw, from thence it proceedeth all along the latitude or breadth of the same Lid, and is instantly enlarged and returned to the outward angle toward the vpper part of the orbe, and passing on by the vpper Lid is inserted with a sharpe end into the vpper side of the inner angle, and so maketh an exact circle, compassing the outward circumference of both the Lids. Yet *Falopius* excepteth the inner part of the great angle, from which it is prohibited that it might not be altogether circular.

Progress.

And insertion.

His vse is, that being drawne toward his originall, it might at one and the same time moue

move the vpper eye-lid downeward and the lower vpward, thereby ioyning and binding them together. And that this is so, it appeareth as well by the continuity of the fibres in the circumference and in the angle, as also by the motion in the same angle, especially if it be a little more constrained so as we must needs winke something withall: and this may be manifestly perceived both by the sight and by the touch. For no-things ioyned can bee strictly drawne together so as they touch one another, vnlesse some parts bee drawne vpward and some downeward. This muscle in respect of his fibres (which are continual) is most truly said to be one, but in respect of the two lids may be called two semicircular muscles: for being separated they make a halfe circle, but ioyned together, they make it perfect. This muscle *Galen* knew, and in his Booke *de vsu partium* at the 9. Chapter, he prooueth how all the motions of the eye-lids are absolued by it, he deuideth it also & addeth, that one of them draweth to the great angle toward the Nose, and the other vnto the lesse toward the Eare, and that when the first draweth the lid is depressed, but lifted vp with the latter. But because the fibres of this muscle are continuall through the whole lid, although it also bee mooued vpward and downward, yet is there no muscle which hath right motion but onely this forenamed circular muscle, which draweth it vpward indeed, but rather toward the inward angle or corner, as it were to his beginning, as every man may perceiue by touching that part himselfe; and yet I know that some thinke this motion proceedeth from the motion of the cheekes.

The vse of this circular muscle

How this muscle may be said to be two.

Why it can bee but one.

Conclusion.

We conclude therefore that the motion of the eye-lids is accomplished by two muscles, one right, which being in the vpper lid eleuateth it; the other orbicular or round and is in both the lids, which when it is stretched doth at the same time draw the lower lid vpwards and the vpper lid downwards: and when there is need of a stronger contraction or closer shutting together; then also the orbicular muscle of the cie brows wherof we made mention before is drawne in to be assistant, like as when we would open the eye more staringly, the muscles of the forehead do much helpe vs.

He that would demonstrate these nice and curious muscles, must haue a very smal knife and very keene, wherewith he must first separate the skinn, in the meane time taking care that he doe not cut the fibres of the muscle, especially in the angles: then shall he separate the muscle below at the *Tarsus* or edge of the lid, and aboue at the eye brow. *Fallopins* in his obseruations confesseth that he was a long time of the same opinion with *Galen* and *Vesalius*, but in the year 1553. tooke knowledge of his error, being admonished partly by *Oribasius* in his Booke *de dissectione musculorum*, and the 29. Chapter, and partly by dissecting the eye of a fish called *Phoca*, which is the Sea calfe, which fish mooueth both his Eye-lids. But we proceed vnto the muscles of the Eyes.

How these muscles may be dissected.
How *Fallopins* came to learne the right muscle.

CHAP. IX.

Of the Muscles of the Eyes.

BEcause our Eyes were giuen vs as spies and scout-watches that wee might pursue profitable things and auoyde whatsoever is hurtfull, Nature made not them im-moueable, for then they should haue discerned only that which was opposite vnto them, for so saith *Aristotle* in his second booke *de part. Animal.* and in the 10. Chapter. We see *per directum*, that is, by a streight line not in euery position saith *Galen*, because oblique, side, backward, higher and lower objects do not fall in with the ball of the Eye. Wherefore it behooued they should be so disposed that they might moue and turne themselues on euery side at their pleasure. These motions according to *Galen* in the third Chapter of his first Booke *de motu musculorum* are fixe in number, and therefore each eye must haue fixe muscles; in beasts there are seauen, especially such as goe on all foure, which deceived *Galen* and some late writers, who were accustomed onely to dissect the Eyes of brute beasts, yet hath the Ape but fixe: The seauenth where it is, may be deuided into two, three or foure. In men, as I said, they are fixe according to the fixe motions of a mans Eye, fower of which motions are right, vpward, downward, to the right hand and to the left: two motions are oblique, to which belong two oblique muscles, whose vse is to rowle the Eye about: notwithstanding one of these is exactly oblique, the other partly right and partly oblique.

How many motions in a mans eye.

All these muscles are seated on the backside of the Eye within the cavity of the Scull whither they accompany the Opticke nerue: and so remaining in their position the Eye

eye.

and they together do make a pyramidall figure. [tab. 1. fig. 6. and 7.] Among these the thicker and more corpulent are the right Muscles, which have all the same structure, original and insertion, and do passe straight all along the length of the eye, the oblique are lesse fleshy. These Muscles are all small, that they might bee sooner mooved, but that which helpeth most the volubility of their motion is the round figure (which is the swiftest of all other figures as we may perceiue by the roundnesse of the heauens) for by it euen in a moment they are conueyed ouer the one halfe of the sky.

The foure right Muscles meeting towards the roote of the Nerue Opticke, doe arise with a sharpe beginning from the lower part of the Orbe which is made by the Wedgebone, hard by the passage through which the Nerue of Sight doth yssue.

I know there be some who imagine that they arise from a mixture of the *Dura Mater*, & a Nerue of the second paire. Others, from the Membrane which compasseth the Orb of the eye, and that other Membrane which inuesteth the Nerue Opticke: some from the *Pericranium* as *Aquapendens*, but we will rest vpon *Bambanus* opinion for their originall. Their whole bodies are fleshy, and they beare out their bellies round when they come forward, and a little aboue the middle of the eye they determine into a broad thin and Membranous Tendon, where-with they compasse the whole eye before, and grow very strongly to the horny tunicle neere vnder the Rain-bow in the great Circle: and these tendons ioyned together do make that namelesse coate of *Columbus*, and the halfe-transparent white of the eye: for I thinke that this whitenes is caused rather by the Tendons of these Muscles then by the coate which they call *Adnata* or the cleauing coate.

But we will giue you a more particular description of them seuerally. The first [tab. 2. fig. 1, 3, 4. D fig. 5. d] which is the third (according to *Galen* and *Vesalius*) is placed aboue, fleshy and round, thicker then the rest, and greater and stronger it is then the second, lifting vp the eye toward the browes: for there is more strength required to lift any thing vp then to pull it downe; it is called the *proud Muscle*, because the motion thereof lifteth vp the eye with a kinde of disdaine.

FIG. V.

Table 2. Fig. 1. sheweth many Muscles of the eye in their own seat. Fig. 2. sheweth the eye rowled Spward whereby his Muscles may be perceined. Fig. 3. and 4. sheweth the Muscles of the eye separated before and behinde with Nerues. Fig. 5. Is the eye of an Oxe, with his Muscles seuered as *Vesalius* doth shew it.

- C, the Muscle lifting vp the eye-lid.
- D, 1, 3, 4. the right upper muscle of the eye in 3, and 4, with the Nerue.
- E, 2, 3, 4. The right lower Muscle of the eye in 3, and 4, with the Nerue.
- F 1, 2, 3, 4. The right externall Muscle of the eye.
- G 1, 2, 3, 4. The right internall Muscle of the eye.
- H 1, 2, 3, 4. The oblique inferior muscle or the pully, whose tendon is marked with a and the pulley with b.
- I, 2, 3, 4. The oblique inferior muscle of the eye.
- a 1, 2. The tendon of the oblique superior Muscle.
- b, The second Muscle of the eye-lid lying in the cavity of the eye, whose broad Tendon b is inserted into the eye-lid.
- c, 5. The haire of the eye browes.
- d, 5. Two right Muscles leading the eye vpward and downward.
- e, 5. Two right Muscles mouing vnto the right and left side.
- f 1, 5. Two right Muscles lightly turning the eye.
- x 1. The seauenth Muscle which may be diuided into more.

The

The second [*tab. 2. fig. 2, 3, 4. E. fig. 5. **] is placed in the lower part opposite to the first, and according to *Galen* and *Vesalius* it is the fourth: it draweth the eye downward towards the Cheeks, and therefore needed not to be so great as the former; for the eye declineth with his owne weight: it is called the depressor and the *bumble* Muscle, because in bashfulnesse we draw our eyes downward toward the lower lid.

The third [*tab. 2. fig. 1, 2, 3, 4. G. fig. 5. **] according to *Galen* and *Vesalius* the first, is seated in the greater angle, and leadeth the eye inward toward the nose, and is called the *To-leader* and *Bibitorius*, we may call it the *squinting* Muscle.

The fourth [*tab. 2. fig. 1, 2, 3, 4. F. fig. 5. **] the second according to *Galen* and *Vesalius*, is opposite to the third, seated on the outside of the eye which it draweth outward to the lesser angle or to the temples, and is called the *Pro-leader* or the muscle of *Indignation* or the *Wayward* muscle.

By these foure if they moue together the eye is drawne inward, stablished and contained, which kinde of looke wee in our language call a *wist-looke*, the motion the Latines call *Tonicall*.

The fift [*tab. 2. fig. 2, 3, 4. I. fig. 5. B*] is the fift also according to *Galen* and *Vesalius*, but the fift according to *Falopius*, *Platerus* and *Laurentius*. It is seated on the outside in the lower cavity, and ariseth betweene the eye and the tendons of the second and fourth Muscles (which is the reason why some haue thought that it taketh his beginning from the eye and is againe inserted into the same) from that cleft which appeareth like a suture of the bone of the lower orbe where the first bone of the law is ioyned with the fourth: sometimes it ariseth with a fleshy beginning from a bony scale.

It is slender, round, short and exactly oblique, and passeth obliquely toward the outward angle, as it were to embrace the eye with a short and somewhat round tendon, and is implanted with a thin and sinnowy end in an oblique line by the Rainbows side neere the insertion of the sixth muscle: so that sometimes the tendons of them both seeme one and the same.

To recite here the Altercations of Anatomists about this muscle would rather intangle our Readers then giue them any great satisfaction; especially seeing such learned men to whome so curious disquisitions will not seeme tedious, may repaire to those fountaines from whence we haue deriued these riuers: wee passe vnto the vse, which is by the contraction of his fibres to rowle the eye obliquely downward toward the outward angle.

The sixt [*tab. 2. fig. 1, 2, 3, 4. H. fig. 5. **] so also according to *Galen* and *Vesalius*, but the sixt according to *Falopius*, *Platerus* and *Laurentius*, is seated on the inside and the vpper part, yet vnder the right muscles, and is partly right and partly oblique. It ariseth from the same place with that which draweth the eye directly to the inner angle at the side of the opticke nerves passage on the backe of the orbe.

It determineth as well in man as in beasts into a round small and long [*tab. 2. fig. 1, and 2. **] tendon almost at the vtmost skirt or edge of the inward angle.

This Tendon is reflected through a small gristle hollowed like a cane or pipe, and placed in the greater angle which *Falopius* first of all found out, and called it *Trochlea* or the pulley, and thence proceeding obliquely to the right angle [*tab. 2. fig. 1, and 2, B, but in the 3, and 4. figure it is shiuen from the bone*] toward the vpper part of the eye, it is inserted betweene the first and the fift muscles somewhat oblique; all which time the foresayde Tendon is compassed about with a certaine Ligament as it were with a sheath. This Muscle (being drawne inward to his originall with his tendon) turneth the eye in a circular motion to the inward angle. These two the one aboue the other below, are called the *Rowlers* or the *Muscles of Loue*: the sixt also some call *musculus trochlea*, or the *Muscle of the Pulley*.

The seauenth Muscle which is for the most part found in brute beasts [*tab. 2. fig. 5. **] is set vnder the former fixe, and hath in it selfe that figure which the former fixe doe together make: it is short and compasseth round the opticke nerue [*tab. 2. fig. 5. **] yet is there some fat betweene them; proceeding forward it is dilated, embracing the whole globe of the eye at the roote; it maketh also a circle even as the foure first neare the Rainbow did make a circle with their Chords: at his insertion which is into the hard tunicle of the eye, it becommeth fleshy and may be deuided into 3, or 4. so as *Galen* doubteth whether it be one, or double, or treble.

The vse of this muscle is to tye vp and strengthen the eyes of brute beasts hanging

alwaies downeward that they should not fall with their owne waight; it also encompasseth the nerue optick making his passage more straight, so as in violent concussions or motions it may neither leane against the bone nor be indangered by distention.

Why a man
hath not the 7.
muscle.

This Musle, Nature or the God of Nature rather did not see needfull for man; because he hath a countenance erected vp to heauen; and if at any time he be constrained to looke downeward, he hath all the right muscles with their ioynt strength to sustaine the Eye, because they grow with their fibres to the membrane which compasseth the orbe.

How to make
diffetion to
shew the mus-
cles best.

To finde out the muscles of the eye, when the braine is taken away you must cut the orbe at each corner euen to the nerue opticke with a Saw, hauing a great care least the *Trochlea* or Pully which is in the inner angle be offended. Then you must separate the *Pericranium* from the bone, and breake the vpper part of the orbe backward, then take away the fat, and so shall you perceiue the muscles of the eye-lids and of the eyes themselues together with their vessels: and if you would obserue the proper and peculiar motion of euery muscle; you must preserue them in their proper position, and tye to euery one of them a thred not far from their tendons and then draw the thred. You may also take the eye whole out of the orbe together with the *Trochlea* which is in the inner angle, and so demonstrate what you please. And thus much of the Muscles of the Eye.

CHAP. X.

Of the Muscles of the outward Eare.

Although most commonly mens Eares are immouable, and few there be who haue any sensible motion of them; yet that the moouing faculty may flow into them, is manifest as wel by their muscles whose action is motion, as also by the nerues

which

which thereabouts are commonly seene. Now the reason why this motion is so rare and so hardly perceiued is three-fold.

The first, because the muscles of the Eares are so small (*Galen* in the 6. Chapter of his 16. Booke *de vsu partium*, calleth them but delinations of muscles) and the nerues so thredy that a sufficient quantity of mouing spirits cannot be conuayed through them.

The second, because if they should be moued the hearing would be depraued or vitiated, especially mens eares being small, and therefore Nature hath made recompence by the easie and speedy motions of the Head whereby wee turne on euery side to receiue the sounds; whereas in foure-footed beasts their eares being greater and the motions of their heads not so nimble, they are alwayes moouable to receiue the sounds from euery side, with them also they driue away Flies which men can doe with their hands.

The third reason is because mens eares are short and gristly, so as the muscles and branches of the sinnewes cannot be dilated in them. But such as they are we owe the honour of their inuention to *Fallopianus*. They are of two sortes, Common and proper, and conspicuous enough in those men whose eares we can perceiue to mooue.

The first is common to the eare and to both the lips, and is a small portion of that Muscle which is accounted the first of them which mooue the Cheeks, and the skin of the face called *Quadratus* [*tab. 3. fig. 1.*] or the square Muscle. This sometimes becommeth fleshy and ascending with his Fibres to the roote of the eare [*tab. 3. fig. 1. O*] is inserted vnder the lap, and draweth it downward to this or that side. This Muscle is broad, thinne and foure sided.

The second, which is a proper muscle [*Tab. 3, Fig. 1. neere to B, tab. 4. fig. 1, B B. fig. 2. A*] is seated in the fore-part, and lyeth vpon the temporall muscle, arising from the vpper end and extremity of the muscle of the forehead, where it toucheth with the temporall:

TABVLA IIIII.

bb, The vpper eye-lid hauing a Muscle with transuerse Fibres.

cc, The eye-brow hauing a circular Muscle, whereby the externall parts of the eye are exceedingly constringed, as *Placentinus* saith,

this

- His insertion.** this descending toward the eare becommeth narrower, and at his insertion into the vpper part of the eare very tendinous; it is thinne being produced out of the fleshy Membrane, which is but sprinkled with fleshy fibres, as also are the other Muscles of the eares: it is much lesse then the temporall, and from roundnesse becommeth long. His vse is to draw the eare vpward and forward.
- The third.** The third [tab. 3. fig. 1. neere to O] ariseth from the nowle or *Occipitium*, and from the coverings of his Muscles about the Mammillary proceffe or teat-like extuberation, where the Muscles that mooue the head and the shoulder-blade do end. In his beginning hee ariseth narrow but passing downward ouerthwart becomes some-what broader, as if it were diuided into two or three fingers, and is so implanted on the backe side of the eare to draw it backward and something vpward.
- The fourth.** The fourth proceeding from the same Teate-like extuberation or Mammillary proceffe, vnder the Ligament of the gristle of the eare, is of a broad, fleshy and fibrous substance, but in his progresse becommeth narrower till it end in a Tendon, which tendon is fastned into the whole roote of the eares gristle [tab. 4. fig. 2. H] one part of it about another part in the middest, and the third below. And hence it was that *Placentinus* a studious and painfull Anatomist, out of this masse maketh three [tab. 4. fig. 2. B C D E F G] muscles led hereunto by his insertion; all which notwithstanding he saith do arise confusedly out of one place.
- Placentinus his conceit.*

CHAP. XI.

Of the Muscles within the Eares.

The motion
within the eare

BEcause these Muscles are very small, euen the smallest in the whole body, and beside their position depending vpon the curious parts of the eare, we haue described them more at large before in the 19. Chapter of the 8. Booke, wherefore heere we will onely make a little mention of them and trouble you no further in this place. The Hammer and the Anuile haue but a very obscure motion, yet are they mooued, together with that Membrane whereto the Hammer is tyed, vpward and downward by one Muscle within the membrane and another without it. The inner muscle [tab. 5. fig. 2. i] was first described by *Eustachius*, and is seated in the Rock-bone. It is the least in the whole body, so also it is of the most elegant and dainty composition. It ariseth in the basis of the bone called *Sphenoides* or the wedgebone in that place where with the roote of the proceffe of the Rocke bone and an additament of the Nowle-bone, it maketh a broken hole. His beginning is like a Ligament, afterward it becommeth fleshy, and by degrees euen vnto the middest groweth a little broader, after becomming narrower againe, it endeth into exceeding small tendons, [tab. 5. fig. 5. below i] wherof one is infixed in the higher proceffe of the Hammer, and the other vpon his necke. This Muscle draweth the head of the Hammer obliquely forward and inward, leadeth it from the Anuile, and driueth the Membrane outward from the crooked proceffe of the Hammer.

The finalnes &
elegancy of it.

This fift Table is all one with eleuenth Table of the eight Booke.

The second
muscle.

The other Muscle, is seated about the middest in the vpper part of the Hole of Hearing, called *Meatus auditorius*, without the Membrane of the Tympane or Drumme. And about the inuention of this Muscle, two of the best Anatomists of *Padua* in *Italy* doe contend.

The first in-
uenter thereof.

For *Hieronimus Fabricius ab Aquapendente* affirmeth, that he found it in the yeare, 1599. Also *Iulius Casserius Placentinus* saith, that he obserued it first the seauenth day of March, in the yeare 1593. Which of them was the first inuenter I cannot say, but both their diligences deserue great commendations.

The vse both of the former internall, and also of this externall Muscle *Aquapendens* expresseth on this manner.

The vse.

The vse of these Muscles is to preserue the Membrane, which being in danger to be broken or stretched in two places, both within and without; Nature hath provided a defence on eyther side. For on the outside the externall ayre being violently mooued together with the sound, might drine the Membrane inward: and within the Included spirit or the ayre passing from the mouth into the passages of Hearing, might offer violence

vnto

vnto the same membrane by driuing it outward, as in oscitations or yawning gapings, in blowing of the Nose, in retention of the breath, in straying of the Voyce, in emptying the belly, and such like: and therefore the outward Muscle beeing drawne inward together with the membrane by the violence of the ayre, doth with his owne motion retract it outward againe, and contrarywise the inner muscle when the membrane is thrust outward retracteth it backe againe inward: and thus these two muscles keepe the membrane from breaking. And truly it is very necessary that this office of the custody of the membrane should be committed to a muscle & not vnto a ligament: that as the impulsions or motions of the ayre against the membrane be diuers, so the cohibition or restraint and retraction of the membrane toward his owne feate should also be diuers. Now we know that a ligament worketh alwayes after the same tenour or manner, but the muscles as being more voluntary doe worke with a kinde of proportion and measure contracting or relaxing more or lesse as neede requires, and with a diuers motion resisting, yeelding to or amending the impulsions and agitations of the ayre: thus farre *Aquapendens*. He that desires further satisfaction about these muscles let him looke backe to the 19. Chapter of the 8. Booke.

Why these
must needs be
muscles not li-
gaments.

CHAP. XII.

Of the muscles of the Nose.

BEcause the motion of the wings of the Nose is very requisite in sodaine and large inspirations and expirations, therefore Nature hath made them moouable with voluntary motion, for which cause there are certaine muscles inserted into them. For albeit the dilatation & constriction of those wings might be done by the muscles of the lips which also touch them (as also the first muscle of the cheeks which is made of the fleshy membrane [tab. 5. fig. 1. y] and inserted into the roore of the nose) yet we have obserued in them that haue large noses called *Nasuti*, some muscles peculiar vnto the nose it selfe, and these are of two sorts: some seruing for dilatation, others for constriction. I am not ignorant what a medly of opinions there is amongst Anatomists concerning the number vse and scituation of these muscles: but I will content my selfe in this place to follow *Baehnius* only.

Why the no-
strils haue
motion.

The muscles therefore which serue for dilatation of the wings of the nose are foure, two very small ones which arise on either side one from the cheek bone (neare vnto the third muscle of the lips) and the bony canale or pipe which is neare the nostrils. These are more fleshy then sinowy, and proceede ouer the ridge of the Nose and are inserted partly into the outward wing, partly into that part of the vpper lip which they call *Filtrum*.

They are of
two sorts.

Muscles of di-
latation.

The vse of it is to draw that part of the lip together with the wing of the nose outward and vpward whereby it also openeth the nostrils. [tab. 5. fig. 1. F] For as saith *Varolius*, because we smell by a kinde of Traction, together with the wings of the nose the nostrils also doe close and are somewhat obstructed; and therefore in smelling the holes of the nose which we properly call the nostrils are by these dilating muscles opened and so kept.

The vse.

The two other muscles doe arise with a sharpe and fleshy beginning from the suture or seame of the forehead where they are mingled with the ends of the forehead muscles vnto the middle of the distance betweene the eys and the spine of the nose: their forme is almost Triangular, and they descend downward obliquely about the bones of the Nose, where becomming broader they are implanted into the wings, and with their right fibres do draw them vpward and dilate them.

The 2. other
muscles of di-
latation.

There are also foure muscles which doe constringe or contract the Nose, two of which doe arise fleshy about the roots of the wings, but they are very small: these passe overthwart about the wing and imbrace it, and are inserted at the corner of the nostrils. The vse of these is that being contracted to their originall they presse downe the wing, and so shut the Nose, [tab. 5. fig. 2. neere K] The other two are hid within the cavity of the Nose vnder the coate wherewith the hole is compassed: these are very thin and membranous, and doe arise from the extremity or end of the bone of the nose, and are inserted into the wings; which wings by drawing them inward they constringe or streighten, and these muscles as also all the rest in this chapter described are not found in all, but in such onely as haue large noses, as we said before. [tab. 5. fig. 2. vnder K]

The 4. muscles
of contraction

CHAP. XIII.

Of the common muscles of the Cheeks and the Lips.

Four com-
mon muscles.
The square
muscle.

He muscles which are common to the Cheeks and the Lips are foure, two on either side called *Quadratus* and *Buccinator*, the square muscle and the *Trumpeter*. The square muscle [tab. 6. fig. 1. & 2. & 3. & 4. make the circumscription,] for as *Galen* calleth it, the musculous dilatation, or the broad or thin muscle, because it is large and membranous, lyeth vnder the skin of the necke, & also is spread over the lower part of the whole face from vnder the mouth. It is a membrane encreased with fleshy fibres which yet doe not arise from any bone: these fibres do ascend vpward to the middle of the face, ereeping by degrees with a variable course from the regions of the racke-bone of the necke, on the outside of the same where it swelleth most, of the shoulder blades, of the cannell bones and of the brest bones, and so make a broad and thin muscle.

The ancients
before *Galen*
knew it not.
Galen found it

Wherefore if any man shall deny it the name of a muscle, and say it is but a membrane of musculous Nature and substance, or whether he list to call it a muscle, he shall haue my good will, for it is so thin and so membranous that the ancients did not separate it from the skin but fleyed it off therewith; not accounting it in the number of the muscles, as *Galen* saith who himselfe was the first that described it, as appeareth in his fourth booke of Anatomicall administrations, and in his first booke of the dissection of muscles, although hee knew it not when he wrote his Books *de vsu part.* To this membrane many small branches of nerues are sent from the sinewes of the necke and mingle themselves with the fibres; and that is the reason why the membrane in this place is more strongly vnited to the parts then in any place almost of the whole body, and the same disseminatation of the nerues causeth those diuers fibrous passages which are seene in it. For from the breast bone and the middle of the Clauicle or Canell bone his fibres run right in the length of the necke, [from *d* to *e*] and those which beginne from the other parts of the clauicle, from the top of the shoulder, and from the rest of the parts before named, doe bend obliquely vpward, [from *h* to *o* and *H*] and the nearer they are to the spines of the racke bones of the necke the more oblique do they appeare: so that when they come neare the *occipitium* or nowle of the head they are almost transuerse: and yet for all that these fibres make no interseptions in the necke at all, especially that are visible: but when they come vnto the Chin where the vpper lip is ioyned with the neather, [betweene *H* and *z*] especially at the lower lip they are so confounded together that they can bee no more distinguished. We call it the square muscle because it passeth from the vpper part of the necke by the sides of the nowle bone away, toward the eare, & is sometime implanted with fleshy fibres into the root thereof, by the helpe of which

The reason of
the many and
diuers fibres in
it.

Why it is cal-
led the square
muscle.

[Table 6. is the same with the third.]

fibres in those men who haue this position of this muscle, their eares, as we haue said, are moued. Sometime vnder the roote of the eare [*o*] it passeth into the face, and couereth the *Masseter* muscle of the law, and withall groweth more strongly to the Cheeke bone then other where, insomuch as some haue taken this part of it to be the fifth muscle of the Jaw: and from hence it is inserted into the roots of the Nose. The other side of it is ouerthwart the face. [from *o* by *H* to *z*] The third side from the top of the shoulder to the brest bone; [from *h* by *e* to *d*] and this side is very vnequall and is as it were indented. The fourth side to make the quadrature, is from the top of the chinne to the brest bone. [from *z* to *o*.] These muscles doe moue the skinn of the face which is not moued by the musculous substance of the forehead, the nowle, the eares and the nose, or by any of their muscles or by the muscles of the eye lids: But rather as the right square muscle draweth and mooueth both the vpper and the lower lip vnto the right side: so the left drawes both the lips obliquely downeward to the left side: and because they cleaue fast vnto the chinne, therefore they helpe much the opening of the mouth. This is that muscle saith *Galen* in his first booke *de dissect. musculorum*, which first of all in those that begin to be afflicted with convulsions is intended or stretched, from whence come those convulsions which wee call *Cynicke* or *Dogge-spasmes*, because by the contraction of these, men are constrained to writhe and grin like Dogges.

Their vse.

The dogge-
spasme.

The fibres of this muscle *Galen* in his first Booke *de Anatom. Administ.* counselleth the Chyrurgion to be well aduised of, because of their incisions which sometimes are very necessary

cessary in this part. For ignorant Chyrurgions not knowing their course haue by large transuerse sections deuided them so farre that the cheeks haue flown vpward from the skin vnderneath them.

The Muscle called *Buccinator* (either because it maketh the Cheeke which is called *Bucca*, [table 6, figure 2. M] or else because it strutteth in blowing or sounding of the Trumpet which is called *Buccina*, and therefore we call it the Trumpeter) lyeth vnder the former & comprehendeth al that part which is blowne vp when we sound a Trumpet. It is round and ariseth almost from the whole length of the vpper law, and is inserted into the length likewise of the lower law at the roots of the Gummes; or if you list to thinke with *Columbus* & *Laurentius* it ariseth from the top of the Gummes, and like a circle doth againe determine into the top of the Gummes. For it being like a circle wherein the beginning, the middle and the end are all one, it skilles not much whether you say it proceedeth from below vpwards, or from aboue downewards.

Thin it is and membranous wouen with many fibres, from whence come the variety of the motions which it performeth, within and without, aboue and below. To this Muscle on the inside, the coate which compasseth the mouth groweth so fast that they cannot bee disseuered but one of them must be broken.

The vse of this Muscle is whilest the law resteth, to moue the Cheeks and the Lips, and yet euen in eating when the meate is fallen into the cheeks, it serueth as a hand to reach it againe vnto the teeth and to driue it hither & thither amongst them, that the aliment might be better broken and shred, and so prepared to be boyled into Chylus in the Stomacke.

Besides these there is a double vse of the cheeks and of their cauities as *Archangelus* hath well obserued. The first, that if any thing in eating doe fall from the teeth outward it should not be lost but be kept within the Cheeks: the other vse is that they might be places of receite to contayne the meate while the teeth be ready for it; as we see in Apes which fill the pusses of their cheeks with meate which afterward they chew. Moreouer, in man they help much for pronounciation and in winding of a Horne or Cornet and sounding of a Trumpet; for if these cheeks be puffed vp a man may obserue the diuers motions of this Muscle by rowling his mouth outward, vpward, downeward, forward and backward.

CHAP. XIII.

Of the proper Muscles of the Lips.

The vse of the Lips in all creatures is for Eating and Drinking, and therefore Nature hath provided their Lips according to their Dyet. The Assie can mumble a Thistle as well as a Man can cate Lettice, whence the prouerbe is, *Similes habent Labra Lactucas*, Like Lettice like Lips. But because there is another vse of the Lips in men, for forming of words, for casting forth of spittle and to preserue the Teeth from the coldnes of the aire (that I speake not of the ornament which they are to the mouth yea to the whole face) for these reasons I say, it was necessary that the Lips should haue voluntary motion, and so the instruments of the same, that is, muscles.

Many of the Ancients and late writers also thought that both Lips were moued by the helpe of the broad Muscle before spoken off, because the great variety of his fibres they thought sufficient for the accomplishment of al necessary motions in that part. But the more diligent Anatomists, beside those aboue named common to the Lips and the Cheeks haue found out other proper muscles belonging to the Lippes alone, about the number whereof they doe not agree. We for this time will conclude that they are fixe, on each side two belonging to the vpper Lip, and on each side one belonging to the neather.

The 1. paire of the vpper Lip [tab. 6. fig. 1. GH] ariseth from the vtter seame of the Iugal or yoke-bone, and that which separateth the first bone of the vpper law from the third and from the cheek-bone. In their beginning they are broad and fleshy, and descend obliquely forward, inserting themselues into the sides of the vpper Lips, which they moue vpward & downward, inward and outward: and that by reason of their diuers fibres diuersly commixed among themselues and wouen with the skin: from which notwithstanding if the body be musculous or fleshy & not fat & the workman diligent, it may be after a sort separated.

X, the 4. muscle of the shoulder blade arising from the necke.

from the cavity vnder the cheeks; is inserted into the bridle where the Lips do meet, and they say it turneth the vpper Lip downward.

The lower lip hath one paire [tab. 4. fig. 2. Z, and tab. 6. fig. 2. N] which ariseth fleshy from the lower part of the vpper iaw, where there is a kinde of asperity or roughnesse at the sides of the chin: thence bending obliquely vpward and becoming broad (for it is broader and shorter then the former paire) are implanted into the middle of the lips, with whose skin as the former they are so mingled, that the Fibres do in a kinde of finger-fould cut betwixt one another.

Their vse.

Eight feuerall motions by these muscles.

By the helpe of these Fibres the motions of the lips become very Diuers, so that *Galen* writeth in his 11. Booke de vsu part. and the second de Dissectionibus Muscularum, that by these muscles (which yet he would haue to be foure) there are 8. feuerall motions effected, foure oblique, two in each lip: and beside them foure other right, two altogether right, eyther when the lips are furthest asunder, the one yeelding vpward to the nose, the other downward to the chin: or when the lips are close ioyned, the vpper being drawne downward, and the lower vpward.

For as in the wrest of the arme right motions are made by the confluence or concurrence of oblique motions, so is it also in the lips: for if the muscle of either side do alone worke, that motion is made side-long, but if both of them be at once stretched, then shall the same lip be after one and the same manner drawne vpward by the vpper muscles and downward by the lower. Thus *Galen* exemplifieth the vse of these muscles in the places last aboue named, to which he that desires more satisfaction may haue recourse, wee will follow our story.

The Corral of the Lippes.

The Vse of the Corral.

To these muscles before described that fleshy and rude lumpe [tab. 7. fig. 3. C] and yet musculous may be added, which in the circumference of the mouth maketh the lips both aboue and below, which by some is made a peculiar paire of muscles of the face: we call it (if you please) the Corral of the lip. *Falopius* diuideth them into two muscles, whereof one garnisheth the vpper lip, the other the lower: and he ascribeth to them as to other muscles their feuerall motions, gathering and wrinkling themselves vp, and with them the flesh of the lips when we would make our mouths little.

CHAP. XV.

Of the Muscles of the lower Jaw.

OF the two Iawes, the vpper as wel in man as in al other creatures is immooue-
able excepting the Parrot & the crocodile, the lower is necessarily mooued for
the breaking and preparing of our meate, and the articulation of the voyce. The
motions of this lower iaw are of two kinds, simple and compound, the simple
motions are fixe, and the compound but one. The fixe simple motions are vpward and
downeward, to the right hand and to the left, foreward and backward. The compound
motion is made of the right and the left, the forward and the backward, whereby the
iawes seemeth to be carryed round. The motion vpward is performed by the temporal
muscle, downeward by the Diagastricke; to the right hand and to the left by the first grin-
der called *Mansorius primus*: backward by the other *mansorius* or the muscle that lurketh
in the mouth: forward by the fifth paire.

The motion vpward and downward is to bite, or to share or cut: the motion to the sides
whether it be to the right hand or to the left, foreward or backward is to grind: for the
meate falleth vpon the teeth of the lower iaw, as vpon the moouing stone of a Mill. For as
in a Mill the weight of the vpper stone breaketh the corne vpon the lower: so the meate is
ground betweene the vpper teeth which resemble the fixed or immooueable stone of the
Mill, and the lower teeth set in the lower iaw which resemble the moueable stone. And
therefore these Muscles are called *Molares*, that is, the grinders, & because their act is called
Mastication or chewing, therefore they are called *Masticatorij* or *Mansorij*, that is, the
chewers. Wherefore the Mouth is opened, shut, drawne in compasse by five muscles on
either side. The first is called *Temporalis*, *Galen de dissect. musculorum* 6. ca. it *Crosophita* [tab.
6. fig. 1, and 2, B: tab. 4. fig. 2, his circumference is noted by N N N, his fleshy part by Q Q Q, conered
yet with the pericranium at O and the Membrane retracted or drawne backe at P] we call it the
Temple or temporal Muscle because it is seated in the temples that is in the side of the head
at the vpper and forepart of the Eare. This muscle is strong and stiffe, and the largest of
all the rest; filling all the cavity of the temple bones. It ariseth [tab. 6. fig. 2, a b γ] with a
broad fleshy and semicircular beginning or originall from the first bone of the vpper iaw,
of the forehead, of the forepart of the scull, of the temples and the *Sphenoides* or wedge
bone, and becomes by degrees more fleshy, and growes narrow vnder the yoke bone called
Jugale which runneth vpon it & about it ouerthwart [tab. 6. fig. 2. 6] & to which it groweth
a litle for better defence, and is inserted with a short nervous and exceeding strong Tendon
to the sharpe [tab. 7. fig. 4. b] proceffe of the lower iaw imbracing it very firmly with his
large armes.

The strength of this muscle (by which sometimes a man is able to bite a strong naile in
sunder, and we haue known a man therewith to guide a great bell being rung to the height)
is caused by his fibres: for al of them as it were from 3. parts of a circle run vnto his center,
which is to be obserued in the dilatation of the wounds of this part & must sometimes neces-
sarily be made, as also because of the apostemations of these Muscles that the Chyrurgion
may know how to make incision according to the rectitude of his fibres, lest if hee wound
them ouerthwart, their vse and action should perish, and the life saith *Columbus* with it.

The vse of this Muscle together with his fellow is, if they draw directly vpward to lift vp
the lower iaw, to bind it strongly and to shut the mouth. But if one of them draw alone, then
is the traction of the iaw oblique, although *Vesalius* thinketh that this oblique traction is
made by 3. muscles, the temple muscle, the *masseter* or chewer and that that lies hid in the
mouth; whence it is that some make three *masseters*, but *Hippocrates* in his *Booke De Arte*,
mentioned but two. This Muscle the Ancients and amongst them *Hippocrates* and *Galen*
haue preferred before many others & admired in his composition the wisdom and prou-
idence of the Creator in making it diuersly according to the diuers vse of the creature.

Galen also in his 11. Booke of the vse of parts and the third Chapter, sheweth how these
muscles if they be wounded do especially bring convulsions, feauers, deepe and dangerous
slecpines, and light frenzies. And *Hippocrates* saith, that the wounds of the temples are
mortall. The reason of these accidents may be because they are neare neighbours vnto the
braine, there being onely the scull betweene, and that parted by the coronall suture or
crowne seame: as also because of the many & large Nerves which are disseminated through

it as *Galen* hath obserued in the former Booke and the 7. Chap. Ad hereto that this muscle hath 3. nerues on either side inserted into him: two from the third coniugation, and the third harder from the first coniugation to giue him the greater strength, for the more nerues and the harder a muscle hath, the stronger it is to performe his action. No maruell therefore if vpon the wounding or concussion, convulsion yea death it selfe doe follow.

The dangers
of the falling
of the iaw.

How nature
hath defended
these muscles.

And hence it is that *Hippocrac.* thought the luxation of the neather law was oftentimes deadly, because thereby this Muscle is distended, and in his Booke *de articulis* he saith, that vnlesse the bones of the neather law be ioyned againe after their luxation the life will be in great ieopardy, by reason of the continuall Feuers and dull and drowsie sleepeinesse which follow thereupon: for these muscles if they be altered from their naturall disposition, and intended or streatched are *soporiferous*: Wherefore Nature for their better defence hath couered them first with a strong, thicke and hard membrane, which is the *Pericranium* or scull-skinne, by reason whereof the muscle on the outside looketh liuid, for his inner part which cleaueth to the bone is altogether fleshy, because the bone in that place is not couered with *Periostion*. And because a part of the *Pericranium* runneth ouer this Muscle, some haue described it with two tendons, one inward and another outward.

The second
defence.

Another defence it hath is this; that the lower part which is neruous is walled with the Iugall or yoake-bone, that the nerues (saith *Galen* in the 8. Chap. of his 9. Booke *de usu partium*) should not be hurt, so as this bone seemeth to haue beene made only for the behoofe of this muscle.

The third.

In what crea-
tures these
muscles are
greatest.

In what crea-
tures least.

Thirdly, the Tendon of this Muscle is defended aboue and below with flesh that it might be better secured from outward iniuries. The difference of these Muscles according to the variety of creatures is after this manner: First of all in men they are the least and least neruous ordinarily; among beasts they are the least in Apes, I meane according to their proportion. They are greatest and largest, as also most neruous in such beasts as haue their teeth set like a Saw, as Lions, Wolues, Dogges and such like. There are other creatures wherein they are very large but not so neruous; large not so much for the strength of the action, because those great creatures doe feede most what vpon the earth, but that they might be proportionable to the magnitude of the lower law; such are Asses, Horses, Oxen, Cammels and such like, as we may reade at large in *Galen* 11. Booke *de usu partium* and the second Chapter.

Why least in
men.

They are least in men both because our neather law in respect of other creatures is the very least, and beside, because our teeth are giuen vs only to breake our meate and for no other vse: for a mans fortitude consisteth not in the strength of his lawes, neither doth he thereby curbe and keepe in awe the other creatures but by reason and by his hands. Notwithstanding they are the greatest of all the muscles of the law, because they almost sustaine it and lift it vp as if it hung and depended onely vpon them.

The 2. mus-
cle of the lo-
wer iaw called
the grinders.

The second Muscle of the lower law is called *Masserius primus*, *Masseter & molitor*, names all taken from the vse of the Muscle which is called *Manducation* or chewing, & therefore we may well call it in our English the Chewing or the grinding muscle. His position is in the cheek [tab. 6. fig. 2. & tab. 7. fig. 3. 1. tab. 4. fig. 2. V] & it hath a double head, one neruous proceeding from the ball of the cheek [tab. 6. fig. 2. A] vnto the suture where the law-bone meeteth with a part of the Iugall or yoake-bone, and passeth along vnto the vtmost angle of the law which we call his acute or sharpe proesse; the other head is fleshy and passeth from the yoake-bone [tab. 6. fig. 2. x & tab. 7. fig. 3. at G] toward the chin, and is implanted very strongly [tab. 6. fig. 2. u] with a broad insertion to the whole latitude of the lower law, so as it representeth, saith *Galen* in the 4. Chap. of his 11. Booke *de usu part.* the corner of a blunt or obtuse triangle, the top whereof is neare the ball of the cheek, [A] one side toward the end of the yoake-bone [from A to x] another side toward the lower law [from x to u], and the third and last as it were a Basis ioyneth both the forenamed sides to all the parts of the lower law, being extended or streatched according to his length.

His fibres.

The Fibres of these heads do intersect themselves like this figure x, and thence it is that they moue the law as well on both sides as also forward and backward (for there is a diuers motion required in chewing or grinding the meate) and in compasse: for as the vse and action of the temporall muscles was vehemently to ioine the teeth and the two lawes together, and so to breake whatsoeuer should light between them: so the action of these chewing or grinding muscles is to leuigate or shred small the meate that is before broken by the temporall muscles. To this action the tongue doth not a little helpe, which like a

hand

hand turneth and returneth the meate in the mouth that all his parts may come vnder the Breake; which motion of the tongue is performed by a muscle of the Tongue called *Linguae Masticator* or the Tongues Chewer, and not onely so, but also the muscles of the cheeks are of great vse toward the performance of the foresaid worke.

The third payre of muscles [tab. 7. fig. 4. neere to B] is situate vnder the temporall muscle in the lower part of the cavity of the Temple bones, and taketh his beginning partly from the vpper & vtter parts of the processes called *Aliformes* or like vnto wings which are sharp and vnequall; and partly from the rooffe and sharpe top or height of the bone called *Sphenoides* or the wedg-bone, which in the cavity of the temples looketh directly against the yoke-bone, where it hangeth ouer a large rift made by the same *Sphenoides* and the greatest cheeke bone.

The 3. paire of muscles of the lower iaw

The original or head of this muscle is partly neruous and partly fleshy, and having gotten this fleshinesse it is led obliquely backward and is inserted into the necke of the lower iaw, and into the inside of his head. His vse is to mooue and lift forward the Iaw, as the next that followeth mooueth it backward.

The fourth muscle is another *Manforius* which *Galen* in his fourth Booke of Anatomicall administrations the fourth Chap. and diuers other places, calleth the muscle lurking in the mouth, [tab. 7. fig. 4. O] because it lyeth hid in the great bosome of the inside of the Iaw. This muscle is thicke and short, and ariseth very neruous from the inward cavity or hollow pipe of the wingy processes of the wedge-bone called *Sphenoides*; afterward becomming fleshy, large & thicke, it descendeth with right fibres, and is inserted with a strong neruous and broad tendon to the inner and backe-part of the lower Iaw where the roughnes is, and where the bosome or hollownes is fashioned that it might not take vp too much roome about the Almonds of the throate. And this muscle (saith *Galen*) helpeth the temporall muscle to which it groweth strongly neere the production and insertion of this tendon; for it draweth the Iaw inward and vpward, and shutteth the mouth, because it is a matter of labour to draw a heauy thing vpward, and to breake and grinde a hard substance: besides when the Iaw is brought forward it draweth it backward againe. The fift Muscle called *Graphioides* or *Digastricus*, double bellied [tab. 7. fig. 3. O P, and fig. 3. N O, tab. 6. fig. 2. O] is thin and small; arising membranous and very broad from the Appendix called *Styloides* (*Galen* called it *Graphioides*) because the Ancients vsed to write vpon waxen Tables with a Probe which they called *Stylus*; and immediately becommeth fleshy and round and passeth vnder the lower part of the vpper Iaw and the eare, & in the middest where it is curued or crooked at the turning of the lower iaw it loseth his flesh and becommeth Neruous: and againe recovering his flesh is inserted into the middle of the iaw fast by the lower part of the chinne, where the inner bone becommeth a little rugged for his better insertion, and where both the Muscles of each side do meete; albeit about his middest it cleaueth to the bone called *Hyoides*. There is also in this place a kinde of forme of a Pulley; for because these Muscles do not arise from the lower parts of the necke but rather from the vpper, they could not mooue the Iaw downward vnlesse they had beene wound about the lower angle of the lower Iaw, as it were about a Pulley.

The 4. muscle of the lower Iaw.

The fift and last muscle of the lower iaw, His variable substance.

The vse of this paire of Muscles is to draw the Iaw downward, and so to open the mouth and by consequence to draw the tongue toward the throate: but if one of them onely do mooue, it leaderth the Iaw obliquely to his owne side. It was called *Digastricus* because it hath two Venters or Bellies, being fleshy in the beginning and in the end, and in the middle [tab. 7. fig. 3. betweene O and P fig. 4. betweene N, and O] neruous or tendinous (which is peculiar to this and to the second paire of muscles of the bone *Hyoides* [tab. 7. fig. 3. V, V] and to the fift proper paire of the Larinx or throttle) partly for more strength, partly that it might not take vp too much roome because the place is but narrow, and there are many Instruments to fill it vp, especially the muscles of the tongue and of the *Hyois*: and therefore also they were made small and thin, round and long, their motion beeing but easie: for the iaw fals downward with his owne weight, and therefore needed no strong retractor.

The vse of these muscles together.

What muscles haue 2. bellies

Finally, because a part of the square muscle (which with *Galen* we reckoned among the muscles of the cheeks) groweth more strongly to the bone of the lower Iaw, the right and the left meeting at the middle of the chin to draw the same downward; therefore *Arantius* (who did not acknowledge the third paire aboue named) maketh it the fift paire of the Iaw, and saith, that this portion or part of the square muscle together with the fourth paire called the *Digastricks*, do open the mouth and draw the Iaw downwards, yet so that it is

The reason of Arantius his opinion.

The vse that Arantius misteeth

more directly drawne (without the motion of the cheeks) by the fourth paire; but by this fift paire as he accounteth them, the iaw is wrested obliquely together with the cheeks and the lower lip side-ward if but one of them moue; if they moue together, then it inclineth it to neither part but leadeth it toward the throttle.

CHAP. XVI.

Of the Muscles of the Chops which serue for Diglutition or Swallowing.

Alen first of all men described the muscles of the Chops, whome after *Oribasius* his *Epitomizer* and *Auicenna* followed, making one on each side. Among the later Anatomists *Falopius* was the first who described three paires; which are seated in the Mouth betweene the coat of the palate and the bredth of the Nostrils.

4. paire of muscles of the chops.

We will reckon vnto you 4. paire, whereof two doe dilate and two contract; and therefore they helpe the Swallow because the Chops were of necessity to bee dilated or straightned when the meate and the drinke should passe by them.

The first.

The first paire ariseth thin and neruous from the top of the wedge-bone called *sphenoides* neare the articulation of the lower iaw with the bone of the temple, and descendeth very small and slender by the inward cavity of the *Pterygoides*, and endeth in a neruous thin and broad tendon which passeth over the cleft which is in the end of the *Pterygoides*, and being reflected is inserted into the skinny part of the palate at which the *Vuula* hangeth. If both these muscles moue together they draw the bottom of the chops, together with the *Vuula* vpward and forward; if but one of them moue, then it draweth vnto that side where-in it is seated.

The second.

The second paire ariseth neruous from the same beginning with the former, and declining downewards it is inserted into the sides of the chops where the Tonfils or Almonds doe reside, and taketh vp or at least embraceth all the side and backpart of the Chops. This paire draweth the Tonfils vpward and sidelong, and dilateth the whole cavity of the chops by parting them asunder. These two paires serue to dilate or open the Chops, and some say they hinder the liquid matter that comes vp in vomiting that it passeth not through or into the nose.

The third.

The third paire compasseth the backward and side cavity of the Chops, and ariseth very thin where the head is ioyned with the necke, whence it descendeth and is inserted in the sides of the bone *Hyois* and the first gristle of the Throttle, sometimes also into the roote of the Tongue but obscurely & it constringeth the Chops when a man swalloweth; and as *Falopius* perswades himselfe it helpeth to swallow a great morsell; because in diglutition or swallowing of meat it raiseth vp the throttle.

The fourth.

The fourth paire ariseth very slender from the inside of the appendix called *Sigloides*, declineth forward, & is inserted with a membranous Tendon to the first Gristle of the *Larynx* or Throttle, to the sides of the bone *Hyois*, and the extremity of the rootes of the Tongue: and therefore (saith *Platerius*) it may be said to be a paire common to the chops and to the Tongue, because it draweth the tongue and the foresaide parts backwards and vpward, and constringeth the chops as we swallow. These two latter paire doe contract the chops and somewhat lift vp the throttle that the swallow might be the more facile and easie.

CHAP. XVII.

Of the Muscles of the Bone called *Hyois*.

BEcause the meate when it is broken by both the Iaws and their Teeth, by the helpe of the Muscles of the Cheeks, the lower Iaw and the Tongue, must be swallowed and transmitted into the Stomacke; and that this diglutition or swallowing is a voluntary motion, it had neede of Muscles appropriated thereunto and distinct from the muscles of the tongue, because we can swallow and yet hould our tongues still and stedfast: and beside, the muscles of the Tongue doe accomplish other priuate motions of their own.

These Muscles which serue for diglutition they make to be proper to the bone *Hyois*, both because they are annexed vnto it, and do also moue it vpward and downeward, and to both sides; for the bone it selfe was necessarily to be moouable, because it was ordained

to be helpfull to deglutition. But there are two kinds of muscles which are ioyned to this bone: some haue their originall from it but do serue other parts, as the tongue and the Larynx. Others that take their originall from other bones, and yet are inserted into this *Hyois* and are proper to it, and of these we will intreate at this time, reckoning vp vnto you 4. paire although there be some who account fixe.

Four pair of Muscles.

Of these two paire are numbred with the muscles of the tongue, because the motions of the tongue and of the bone *Hyois* are very neare akin, and therefore it is no wonder if their muscles be mixed and connected together.

The first paire run betweene the brest bone and the bone *Hyois*, and are therefore called *Sternohyoidei* [tab. 6. fig. 2. Q R] and appeare outwardly vnder the skin lying vpon the sharp artery and the gristle of the throtle called *Thyroides*. It ariseth with a broad and fleshy beginning from the vpper and inner side of the brest-bone, and runnes directly vpward, and is implanted very fleshy without a tendon (saith *Columbus*) into the foreside of the basis of the bone *Hyois*. All along their passage they are fleshy and broad, and are diuided in the middest by a line which passeth according to their length. Their vse is to draw the bone straight downward and backward, and by accident also they defend the throtle and the gristle *Thyroides*.

The 1. paire

The second paire called *Genio-hyoidei* [tab. 6. fig. 2. S] are vnder the chin, and the left paire of the lower iaw. [tab. 6. fig. 2. O] They are large and short and fleshy all ouer, and do arise with Fibres of a diuers course from the inner part of the lower iaw, and are inserted with the same breadth into the middle part of the bone *Hyois*, into which also the first payre was implanted. They draw directly vpward and somewhat forward.

The 2. paire

The third paire called *Styloceratocidei* [tab. 7. fig. 2. T] is seated obliquely and vnder the Chinne as the former, and are outwardly stretched vpon the fift paire of the neather iaw. They are slender and round, and arise from the roote of the Appendixe *Styloides* about the originall of the fift muscle of the iaw, and end into the hornes of the *Hyois*, that is, into the laterall or side parts thereof, and they are sometimes perforated in the middest to giue way to the muscle which openeth the iaw. They moue the bone toward the sides and somewhat vpward.

The 3. paire

The fourth paire is called *Coracohyoidei*. [tab. 6. fig. 2. VV. tab. 7. fig. 3. VV] They lye lurking vnder the fourth muscle of the shoulder-blade, as *Vesalius* & *Platerus* haue noted. They are slender and long, and do arise out of the proesse called *Carocoracius* at the vpper end of the shoulder-blade nere his necke, and do run obliquely vpward vnder the 7. muscle of the head, and are implanted where the third paire is, into the beginning of the lower proesse of the bone *Hyois*, and these draw downward vnto the sides. This is along paire, on eyther side fleshy and hath a double belly, and therefore *Galen* cald them *Digastricks*, but in the middle they are slender and neruous as is the fourth muscle of the iaw and the fift proper muscle of the Larynx, and extenuated into the forme almost of a Tendon, haply to giue way to the 7. muscle of the head (which heere runneth ouer him [K]) as to his better.

The 4. paire

Concerning the vse of these muscles, we craue leaue to add yet a little more: some thinke they were not ordained for motion but rather for tension, to tye, establish and suspend the bone *Hyois*, so saith *Laurentius*: others as *Archangelus* thinke, they serue for deglutition, and that they are the proper muscles of the *Hyois*. Others as *Arantius*, because this bone is the basis of the Tongue, and because the basis of any thing can by no meanes bee mooued, but that also must be mooued which is established vpon that basis, do thence determine that these muscles do mooue the Tongue, and so much the rather because the manifold and frequent motions of the Tongue can hardly be imagined to be accomplished by so few and so small muscles as determine or end in the substance of the Tongue. Wherefore these may be called the common Muscles of the tongue and the *Hyois*, into which certaine Nerues are distributed from the sixth Coniugation.

An addition concerning the Vse of these muscles. *Laurentius*. *Archangelus*. *Arantius*.

CHAP. XVIII.

Of the Muscles of the Tongue.

THE Tongue hath three ends in Nature; to speake, to taste, and to rowle the meate in the mouth, which cannot bee performed without motion, and therefore Nature hath

hath allotted vnto it Muscles, which from those three actions may be called, the *Talkers*, the *Tasters*, and the *Rowlers* of meate. In man the especiall end of the creation of the tongue and of the motion of the same is for speech, as in beasts for tast.

The especiall
vse in man.

For because they want hands wherewith to reach their meate or fother vnto their tast, it was necessary they should be able with their tongues to licke and gather it of the earth: but man is able to tast without the motion of the tongue, because he hath hands wherewith to bring that he would tast vnto the instrument or organ of the sense: but both of them haue necessary vse of it in rowling and returning the meate againe vnto the teeth which falleth from them into the space of the mouth.

The bridle of
the tongue.

Wherefore that it might answer those intentions, it was made moueable and had therefore muscles, and not muscles onely, but also a figure fit for motion, some parts being thinner then other: yet because it should not moue beyond his teather, Nature hath restrained it with a ligament, that the body of it which by reason of the diuers fibres it had was infinitely disposed to motion and agitation, might rowle vpon that axletree, or turne vpon those hinges onely: but of these things we haue spoken sufficiently heretofore, excepting of the muscles whose proper place this is.

Muscles of the
tong double.

The Muscles therefore of the Tongue are double, some are common, others proper. Those are esteemed to be common, which haue already bene said to belong to the bone *Hyois*, vnto which the third paire also now to be mentioned may happily be referred: and those proper which hauing their originall other where, do determine and end in the substance of the Tongue.

The 1. paire.

The first paire are called *Styloglossi* or the Auger-tongue Muscles [tab. 8. fig. 1. and 2. F] *Galen dissect. muscul.* 14. calleth them *στυλογλωττι*, that is transuerse. They haue slender originals from the vtter face of the Appendix *Styloides* (as the fourth paire of the throat from the inside of it) and are implanted with transuerse fibres into both sides of the Tongue about the middle thereof, yea they proceede forward and attaine vnto the top of the Tongue; & when the Tongue is lilled out they draw it in againe. But because their Fibres are so wouen one within another, when both of them are at once contracted toward their originall they lift the tongue directly vpward, but when one of them onely worketh then is the tongue lead vpward to one side onely.

[Tab. 8. is the same with that in lib. 8. Tab. 14.]

The 2. paire.

The second paire are called *Myloglossi* or the grinder-tongue Muscles [tab. 8. fig. 1. and 2. G] They arise with broad and inuerted originall and transuerse fibres from the sides of the lower iaw neare the roots of the grinding teeth called *molars*; and are inserted on both sides into the length of the ligament which is vnder the basis or foundation of the tongue, and degenerateth into the bridle by which the tongue is tyed to the Chops. When one of these works we turne the tongue vpward and obliquely, but when both of them moue, then the tip is directly lifted vpward to the palate and vpper teeth. Sometimes this paire doubleth the tongue or maketh it hollow like a gutter, and sustaineth it so in forme of a compassed bow to the palate with the assistance of the ligament and bridle becoming somewhat rigide or stiffe. And if the second paire belonging to the bone *Hyois* doe worke with them, then the tongue becommeth more narrow and solid and is exerted or thrust forth to his extent beyond the lips.

The 3. paire.

The third paire are called *Genuaglossi* or the chin-tongue Muscles. [table 8. fig. 1. and 2. H] They arise with a narrow beginning from an asperity or roughnes in the inside of the middest of the Chin; afterward they become broader and replenished with right fibres, and are implanted into the middle of the tongue the greatest part of them at the roote, yet some part of them runs out toward the tip, so that the diuers parts of the same Muscle do worke contrarily. For the greatest part of their fibres beeing drawne toward their originall thrust the tongue beyond the teeth and the lips, (although *Auerrhoes* thought that a proper motion of the tongue) the lesser part in their action draw it againe inward. Sometimes they communicate some fibres to the bone *Hyois* which they so draw vnto the chinne. They haue also certaine lines in them which Anatomists call *inscriptions* as if they were many Muscles.

Their contra-
rie vses.

The 4. paire.

The fourth paire are called *Basiglossi* or *xyfiglossi* or bone-tongue Muscles. [tab. 8. figure 1. & 2. D O] These doe arise straight fleshy from the vpper and middle part of the bone *Hyois* and in some places are obscurely diuided asunder, as if they were many muscles, & so run along the length of the tongue, and are inserted in the middest of it. Their vse is when they

they are contracted to draw the tongue directly inward or backward toward his root.

The fifth paire are called *Ceratoglossi* or *horne-tongue* Muscles [*tab. 8. fig. 1. and 2. E*] and arise from the vpper hornes (if they be there) of the bone *Hyois*, from whence passing somewhat obliquely or sloping they are inserted into the sides of the tongue neare vnto his root; sometimes they arise from the neather hornes when the vpper are wanting, or are not very bony, but rather like ligaments, which as we haue sayd is most commonly in women which haply makes their tongues more plyable. If one of these onely be contracted the tongue, especially the roote of it, is drawne side-long downward, and so it may be sayd to mooue to the right side or to the left: but if both of them be contracted then is it mooued right downward toward the throate; this paire in Oxen is double, in men it is but single.

The 5. paire.

Why women's
tongues are
gib.

These five paire of Muscles therefore do mooue the tongue vpperward, downward, forward, backward, on the right hand and on the left hand, or to the sides, but if they worke successiuelly, that is, one vpon another, then they turne the tongue round; and all these motions the muscles of the bone *Hyois* do not a little further, which some do rather ascribe to the fibrous substance of the Tongue, which hath indeed all three kinds of fibres.

The substance
of the Tong.

At the root of the Tongue when these Muscles are remooued there appeareth a certaine flesh compounded of many Glandules mingled with fat, which flesh doeth not merite the name of a muscle, because a Muscle doeth not consist of glandules or kernels but of fleshy fibres. [*tab. 8. 1. and 2. H*] This knot of glandules groweth at the roote of the Tongue that with their liquor it might alwayes be kept moyste, because without moysture there can be no perfect taste, no more then there can be any concoction in the Stomack without Elixation or boyling, for the concoction of the Stomacke is not a roasting but a boyling or elixation; and therefore Nature hath ordained the Glandulous *Pancreas* or Sweet-bread to touch the Stomack, that thence there might continually ascend moyst vapors that the concoction of the stomacke might be accomplished by a moyste boyling, not by a dry roasting.

The glandu-
lous flesh at
the roote.

Moreouer, this moysture of the kernelly flesh maketh the motion of the Tongue more glib and glad as we say, or nimble; for when the Tongue is dry (as we may perceiue in those that are exceedingly a thirst) his motions are more flow, the same also we haue experience of in those that labour of burning Agues, in whome all the moysture of the Tongue is exhausted and dried vp. Moreouer, the Almonds of the Throate which we call *Tonsille*, as is before obserued by yeilding a perpetual moysture, doe moysten the Tongue and so further his motion.

CHAP. XIX.

Of the Muscles of the Larynx or Throate.

BEcause the actions of the Throate or *Larynx* are performed with a voluntary motion, Nature hath giuen it muscles, which by their action which is Contraction might bend, extend & mooue sidelong the ioynts of the gristles, that so the *glottis* or Young-let might become mouable and his cleft might be made broader or narrower as need should require: for so it behoued to be, because it was conuenient that our voice as well as our speach should be at our command. The Throate therefore hath two kinds of Muscles, Common and Proper. The Common are fixe, (or three paire) of which foure doe constringe and two do dilate it. The Common are so called because they arise from other parts, and are but implanted into the Throate; and of these we will treat first, because they first fall vnder our view and so come first to be shewen.

The action of
a muscle is
Contraction.

3. paire of
common.

The first paire of the common Muscles [*tab. 9. fig. 6. 20.*] which *Vesalius* and diuers others do make the second, is situated in the fore part of the Throate, one on each side, & we call them *Bronchios* or the weazon Muscles, because they cleaue to the rough artery al along, which is called *Arteria* by *Hippocrates*. For they arise with a fleshy and broad beginning from the vpper and inner part of the Breast-bone at the very *Inguinum* about the clauicles, and with right fibres doe runne vp along the weazon fleshy and a little broader then where they arose, & are inserted into the sides of the shield-gristle called *Thyrois*, below neare the Glandules with a broad and fleshy Tendon, which in man is but one, but in beasts it is deuided in the middest, and in most of them one part is fastned into the throate, the other into the bone *Hyois*. Yet *Galen* is of opinion that this is their originall, and that they are inserted into the breast-bone.

The first
paire.

They

They are very long, because not the shield-gristle or the *Thyroides* onely, but the whole *Larynx* is moved especially in a base voice, where the throttle mooueth downeward, and the whole weazon is contracted in his membranous distances, and therefore it was, that this paire cleaueth to the whole length of it.

They are moreouer very slender, because the throttle easily descending with his owne waight did not require any great strength: yet notwithstanding they haue certaine *inscriptions* or neruous distinctions, such as are in the right muscles of the paunch, by which their length and tenuity is secured from danger.

Their vse is to draw downe the shield-gristle called *Thyroides*, and below to constringe or contract it, and so to dilate the cleft or fissure of the *glottis* or tounge-let in a base voice; they also doe somewhat contract the weazon, that it be not doubled when we speake, or the throttle too much dilated above.

The 2. paire.

The second paire of Common muscles [tab. 9. fig. 3. b] which *Vesalius* calls the first paire as also doth *Falopius* and some others; is situated likewise in the forepart of the *Larynx* or throttle, and are called *Hyooides*, or rather *Hyothyraoides* or the shield-bone muscles, these are opposed to the former and are farre shorter. They arise broad and fleshy almost from all the lower part of the bone *Hyois*, to whose inward sides they seeme to be continued; and with right fibres they creepe downward together, sauing that their inner sides doe depart one from another, and are each of them implanted with a broad and oblique end into the lower part of the Gristle *Thyrooides* which they wholly couer. Their vse is to dilate the lower part of the shield-gristle and to contract his vpper, and by drawing the throttle vpward to make the cleft shorter and narrower; so we may perceiue that in an acute or shrill voice the throttle moueth vpward; but if this muscle doe proceede obliquely backward as often it doth, then it mooueth the shield-gristle or *Thyrois* vpward and forward. I can giue no better reason of their shortnesse, but because the *Larynx* hath other helps to draw it vpward beside these: for the bone *Hyois* being mooued vpward by other Muscles, draweth the whole throttle vpward with it.

Table 9. The same with the 15. Lib. 8.

The 3. paire.

The third paire of common Muscles [tab. 9. fig. 7. ll] are seated in the backpart of the *Larynx*, they are called *oesophagæi* or the Gullet muscles, and truely some thinke they are muscles of the *oesophagus* or Gullet and not of the Throttle or *Larynx*, because they encompassse the gullet on euery side and are thought to helpe much in diglutition. They are altogether fleshy and large, and doe especially ly vpon the vpper part of the Gullet, which they encompassse saith *Galen* like a sphincter, three fingers breadth ouerthwart, and do almost cleaue vnto it.

Laurentius.

They arise from the sides of the Shield-gristle or *Thyrois* al along, where there appeareth a rough line, and passe above the gullet with their Fibres almost transuerse, and there in their extremities or ends they meet, yet so that they are distinguished by a white line running through their length, especially in beasts, for in a man it is oftentimes not visible, and beside the Fibres do not seeme to be diuided, so as they may easily be taken for one muscle. Their vse is, as they contract the sides of the Shield-gristle or of the *Thyrois*, so to presse it that they may binde and streighten the cleft; but as they encompassse the gullet & are drawne into themselues, so by a voluntary motion they help the swallow, and are somewhat assitant to the naturall Faculty as we haue partly opened before. And thus much of the common muscles of the throttle, now follow his proper.

Proper Muscles.

Of proper muscles there are ten (or five paire) sixe of them do dilate, and foure contract; they are called *Proper*, because they both arise from the *Larynx* to which they grow, and againe are inserted into it, imploying all their seruice to it alone, opening the cleft in inspirations or when we take in breath, and shutting it when we breathe out; besides they fasten together the two Cartilages or gristles, which do originally and of themselues helpe the forming of the voyce. Of these muscles some are before, some behinde, others without, others are placed within.

The 1. paire.

Originall.

The first paire of the proper [tab. 9. fig. 4. f, but in the 6. figure one of them is separated, the other remaineth in his place,] which are forward and vttermost we call *Antici Crycothyroidei* or the forward Ring-shield muscles: their situation is in the lower and forepart of the *Larynx*, they arise from the Cartilage cald *Crycois* or the Ring fleshy (but small and hauing oblique fibres) and proceede obliquely till they be implanted into the Basis of the shield-gristle or *Thyrooides* withinward, and in their whole progresse (their middle part only excepted) they are fleshy

fleshy and broad: and if you separate the lower proceffe of the shield-gristle or *Thyroides* from *Crycoides* or the Ring, and follow it with a section, you shall perceiue that there is one in each part.

The vse of these is to moue the *Thyroides* from above downward, to ioyne it to the *Crycoides*, to constringe the lower part of *Thyroides* and to dilate the vpper part, and by that meanes to open the *glottis* or cleft of the *Larynx*.

The second paire are called *Crycoarythenoidei postici*, the backward Ring-Ewer muscles. The 2. paire. [tab. 9. fig. 5. f.] Their situation is in the backside of the Ring-gristle and they arise narrow and fleshy from the lower and backe parts of the same gristle, and running vpward [tab. 9. fig. 5. f.] do fill a smooth cavity made for their sake in the backside of the Ring gristle which looketh toward the Gullet or *Oesophagus*; and at length becomming more large and strong with fibres somewhat sloping or oblique; they fall from the spine or rough line of the Ring-gristle, and are inserted on both sides neruous into the lower part of the Ewer-gristle where it is articulated with the Ring-gristle.

The vse of these is to returne the third Gristle backward to the outside of the *Larynx*, to open the cleft and dilate it to the sides, and so they further the base voice. But as they haue both right and oblique fibres, so they serue for diuers and mixed motions; with the right they draw the cleft backward and so open it; with the oblique they helpe to moue toward the sides; so that they open & enlarge the cleft both in the length and in the breadth of it.

The third paire are called *Crycoarthenoidei laterales* or the side Ring-ewer muscles. [tab. 9. fig. 4. r.] Their original is fleshy from the Ring-gristle where it is broadest, from whence they proceede directly vpward, and become larger and more fleshy, and are inserted to the sides of the Ewer-gristle at the articulation or ioynt, & do occupy all the root of the third gristle which the former paire do not touch.

Their office is outwardly to sunder the double Ewer-gristles, and to separate them one from another so much as the fifth paire drawes them together, and by that meanes they drine out the sides of the cleft and open the throtle. But because these muscles are seated, partly without, and partly within the capacity, happely on the outside they binde or contract the *Larynx*.

The fourth paire called *Thyroidei interni*, the inward shield-gristle, or *Thyroarthenoidei*, that is, the shield-ewer muscles, [tab. 9. fig. 4. c, tab. 8. fig. 1. c. e.] are broad, fleshy, and haue diuers fibres mingled and vnited together, and in their beginnig three inscriptions or distinctions as if they were three seuerall muscles, and are seated ouerthwartwise, in the capacity of the *Larynx* or throtle. They arise close one to the other from the inner, hollow and middle part of the shield-gristle (whose inward cavity they fill) along the whole length of it, and with oblique fibres they ascend vpward, growing narrower in the ascent, and are inserted into the sides of the ewer-gristle which forme the *tongue-let* or *glottis* following the sides of the cleft.

These are the largest and strongest of all the proper Muscles and almost equall all the Muscles of the throtle put together, and that for good reason, namely because in the retaining of the breath they were to resist all the Muscles of the Chest. For in drawing the parts of the Ewer-gristle, vnto the Shield-gristle, and in constringing them or gathering them together and thrusting the *tongue-let* forward, they shut it vp & are said to close the throtle. If in these Muscles there happen an inflammation it bringeth a mortall squinasy there appearing no rednesse neyther in the chops, nor in the mouth, nor in the necke. For in the squinasy sometimes the brest-bone, sometimes the necke looke red: the brest-bone because of the continuity of the weazon muscles, which we saide did arise fleshy from the vpper and inner side of the brest-bone and ran all along the weazon, and were inserted into the Shield-gristle.

The sides of the necke become red, because of the Gullet Muscles which arising from the sides of the Shield gristle doe encompassse the whole gullet like a sphincter: also the fore and vpper part of the necke looketh red, because of the continuity of the Shield-bone Muscles which arising from the bone *Hyois* are inserted into the lower part of the Shield-gristle couering the same wholly.

The fift and last paire called *Arytenoidei* or the Ewer-Muscles [tab. 9. fig. 4. and 5. g.] are scituated outward and backward about the gristle where it resembleth the figure of an Ewer or Water-spout, and where the gullet is ioyned to the throtle, and the third gristle is articulated with the second. They arise from the backe line or spine of the Ewer-gristle,

The vse of their double fibres.

The 3. paire

The 4. paire

The true and dangerous squinasy.

The 5. paire

gristle, and doe runne vp with the oblique fibres to the middle thereof, and where the two parts of the gristle are tyed together they also are ioyned and inserted. These are small, *Columbus* and *Archangelus* say they bee the least in the whole body: on the one side they bunch out like pears, but within they grow to the gristle, in the midst where they ioyned they are broader and thicker, as also where the white line appeareth, and seeme to grow into one in a common Tendon, then they become neruous for more strength that they might not be indangered in their perpetuall motion, especially when we hold our winde vpon occasion long; and therefore some haue accounted them for one muscle, some for two; and because they are on either side fleshy they are to be numbred among those that haue their Tendon in the middest, as is the fifth muscle of the lower iaw called therefore *Digastricus* or double bellied, and also the fourth paire of the bone *Hyois*.

Why the ewer-gristle must be double.

The most acute Squinasy.

The vse of all the muscles of the throttle.

How they differ from the muscles of *hyois* and the tongue.

The vse of these muscles is to moue the ewer gristle sidelong to the right hand and to the left; yea to constringe or knit the basis or foundation of the same, to draw both his parts together, to presse them one to the other, and so to straighten and close the cleft; whereby it is manifest that this third gristle was necessarily made double, for if it had bene single it could not haue bene straightned by these muscles nor shut by the fourth paire, nor opened by the second and the third paires. Moreouer these inward muscles being inflamed the most acute and sharpe Squinasy is ingendred: for when they swell, by reason of the abundance of the matter the outgate of the breath is hindered, and so the patient instantly suffocated, which we haue knowne in the hundreds of *Essex* to happen within 12. houres after the disease began.

The vse of the muscles of the Larinx or throttle as well common as proper, is to moue the gristles thereof with voluntary motion to the infinite modulations or diuers accents of the voyce: so that when part thereof, especially the vpper, is fitly dilated and straightned, or opened and shut; the cleft of it (which is the proper and immediate organ of the voyce) might be either dilated for a base, or streightned for making an acute or shrill sound, which verily the common muscles doe more manifestly, and the proper more obscurely. These muscles are altogether diuers from the muscles of the bone *Hyois*, and of the tongue: for if when they be at rest, you put your hand to your Larynx and offer to sing in base tunes, you shall perceiue the throttle to descend downward, and in shrill and treble you shall manifestly perceiue it to ascend vpwads.

CHAP. XX.

Of the muscles of the Epiglottis or the ouer-tongue.

Diuers opinions of the epiglottis.

In beasts two paire.

The 1. paire.

The 2. paire.

Alen is of opinion that the motion of the *Epiglottis* or ouer-tongue is in a man not voluntary but naturall, or at least he leaueth it doubtfull whether it haue any muscles or no. *Vesalius*, *Platerus*, *Columbus* and *Laurentius* thinke and resolute there are none, yet *Platerus* maketh question whether they be not found in such men as doe easily vomit. Of the same opinion also is *Banhinus*, *Aquapendens* thinketh the motion of it voluntary and performed by membranous muscles. For my owne part I dare not stickle in so nice a question. In beasts that chew the cud they al acknowledge that it hath muscles, those we will briefly describe for the helpe of young Anatomists who do often in the want of mens bodies dissect the throttles of Oxen or Sheepe to practise themselves.

There are therefore in beasts two paire of muscles belonging to the *Epiglottis* or ouer-tong, the first are called *Hyoglotti*, or the bone-tong, the second the Ewer-tongue muscles.

The *Hyoglotti* or bone-tongue muscles are seated in the backe of the ouer-tong, they arise from the middest of the inner part of the bone *Hyois*, and are inserted on either side into the Basis of the *Epiglottis* neare his middle. They raise vp the ouer-tongue after it is depressed in the swallowing of meate and drinke, to make free passage for expiration which otherwise would by it be intercepted.

The Ewer-tongue muscles because of the largenes of the Larinx or throttle are most euident in oxen. They arise fleshy from the vpper part of the Ewer-gristle at his articulation. At their original they are contiguous or touch one another, and for a great space seeme vnited and mingled, and run a long course keeping their proportion through the inside of the Shield-gristle, & at length retaining their vnion or conjunction are inserted into the inner Basis of the *Epiglottis* or ouer-tongue

CHAP. XXI.

Of the Muscles which moue the head.

The head is moued primarily or fecondarily. Primarily about the fecond rack-bone of the Necke or about the first: about the fecond eyther bending forward or extending backward: about the first it is moued as a Naue vpon an Axletree, or rather as the Poyle of a Watch vpon his Bridge. All these motions are performed by feuen or rather by nine proper paire of muscles, (*Falopius* in his *Observations* accounteth ten) 7. of which are *Extenders* and *Compassers*, and are fituated on the backe part in the necke; and two *Benders* which are placed in the forepart of the necke. The head is moued fecondarily and by accident when it followeth the motion of the necke: the muscles therefore of the necke moue the head but onely vnto the sides. For if the necke be not moued, wee cannot incline the head at all to the Shoulders.

The first paire are called *Splenij* or the splintes, because they are very like the rowled splints which Chyrurgeons vse when bones are broken. [*tab. 10. ΔΔ*, their originall is marked with 8, their insertion is with 9.] They are long and thicke, and on both sides rest vpon the racke-bones, and albeit they are very fleshy yet at their originall from the five vpper rack-bones of the Chest (for they rarely reach vnto the sixt) they are finewy. From thence they ascend vward and grow fleshy receiuing a new originall from the Ligaments of the rack-bones of the necke; some thinke they arise onely from hence, some from both places; howfoeuer, their ascent to the head is not direct but somewhat oblique, and from that part of them which proceedeth out of the spines of the chest are produced 2. membranous

Nine paire of Muscles.

The 1. paire

Originall double.

TABVLA. X.

Tab. 10. Wherein some Muscles of the head, the Chest, the arme, and the shoulder blade are described.

1, The proeesse of the shoulder-blade, called the top of the shoulder.

O, The fourth Muscle of the arme or the greater round muscle to which *Falopius* his right muscle is adioyned, which some call the lesser round muscle.

22, The sixt muscle of the arme or the vpper bladerider.

X, The 2. muscle of the shoulder-blade or the *Leuator* or *heauer*.

Z, The second muscle of the Chest or the greater *Saw* muscle.

Γ, The fift muscle of the chest or the muscle called *Sacro-lumbus*.

α β, His place wherein he cleaueth fast to the longest muscle of the backe.

γ γ, The Tendons of this muscle obliquely inserted into the ribs.

ΔΔ, The first paire of the muscles of the head or the *Splinters*.

Ch. 8, 9, Their length whose beginning at 8 and insertion at 9.

10, 11, the sides of this Muscle.

12, that distance where they depart one from the other.

13, the two muscles called *Complexi*, neare their insertion.

φ, The second muscle of the backe or the *Longest* muscle.

Ω, The fourth muscle of the backe or the *Semi-spinatus*.

δ, The shoulder-blade bare.

P, A part of the transuerse muscle of the *Abdomen*.

V v v

Ten;

Tendons which are inserted into the transverse processes of the first & third *Vertebra* of the necke, or sometimes of the second, third and fourth: *Laurentius* will haue them to haue a double insertion; one part of them into the transverse processes of the second Rack-bone, another part into the *Occipitium* of the head toward the sides of the *Labdall* suture, and thither I am sure their fleshy part reacheth. For they are neruous in the Chest, and fleshy from thence forward, their fibres running obliquely vpward from the spine of the lower to the transverse processes of the vpper racke-bones, all of them at length determining in the Nowle: yet *Columbus* saith they are right as long as the two muscles ioyne, and become oblique but after their diuision. For where they arise at the spine of the Chest they make a sharpe nooke or angle which is dilated as they ascend, and about the third Racke-bone of the necke the right is seuered from the left with a notable distance [tab. 10. character 12] so as the space betweene them resembleth a triangle [tab. 10. char. 9, 10, 12.]

Their Implantation is broad and fleshy into the Nowle [tab. 10. from 11, to 9.] and so they haue three sides: one from their beginning to their parting asunder; the second from thence to the Nowle; the third from the nowle backe to their originall. *Falopius* hath obserued that sometimes they are inserted with a neruous particle into the proceffe called *Mammillaris* or the Teat-like proceffe.

The vse of this paire is when they both moue, to draw and extend the head directly backward: but when one of them onely worketh then they turne the head to the sides, and the right moueth somewhat backward saith *Archangelus*.

The 2. paire.

The second paire are called *Complexi* [tab. 11. A B C D E F] or the brayed Muscle, because they are wouen and brayed together with the third and fourth Muscles of the necke like a flat point wouen of diuers threds, or else because of the diuers formes. For their ori-

TABVLA. XI.

Tab. 11. sheweth some Muscles of the Head, the Backe, the Chest, the Shoulder-blade and the Arme.

A D, the second paire of the Muscles of the head or the two *Complexi*, the first part is at A D.

B C, the second part. E F, the third part rising vp vnder G and inserted at F.

G, the fourth part of this muscle or the right muscle of the head according to *Falopius*, which *Vesalius* made the 4. part of the 2.

G G, (Betwixt the ribs) the externall *Intercostal* muscles.

L, the originall of the 2. muscle of the backe.

M, His tendons at the rack-bone of the necke.

The vpper O the fourth muscle of the arme or the greater round muscle.

O O, the lower, the 6. muscle of the Chest or the *Sacrolumbus* hanging from his originall.

Q, The sixth muscle of the arme or the vpper *Bladerider* inuerted.

V, The third ligament of the ioynt of the arme.

X, The fourth muscle of the shoulder-blade or the *heauer*.

Z, The second muscle of the Chest or the greater *Saw-muscle*.

E, the 3. muscle of the necke called *transuersalis*.

Π, the 4. muscle of the necke called *Spinatus*.

S, the first muscle of the backe or the *Square muscle*.

Φ, the 2. muscle of the backe or the *Longest* whose originall is at L and his tendons at the *vertebrae* at M M. (natns.)

Ω, the fourth muscle of the backe called *Spi-*

δ, the backe of the shoulder-blade stayed.

ginals.

ginals are of diuers fashions, and they are diuersly also inserted into the Nowle or *occiput*. They haue many tendinous parts, and many also fleshy, so that each of them seemes to be compounded as it were of three seuerall Muscles, or rather hath three Originals. The first ariseth farre off with a sharpe originall even out of the Transuerse proceffe of the fourth and fift rack-bones of the Chest, this immediately after his springing appeareth fleshy [at A] and of the fashion of a Mouse, when it attaineth vnto the beginning of the Necke [at B] it ceaseth to be fleshy and endeth as it were in a round Tendon, and hauing overcome the roote of the necke at [C] it groweth fleshy againe (as the Muscle of the bone *Hyois* called *Digastricus* or double-bellied) and so is inserted in the middle of the Nowle-bone. [at D]

The second originall or beginning of this Muscle is shorter, growing round and neruous out of the spine of the 7. racke bone of the necke [at C.] *Platerus* addeth sometimes of the first, and sometimes of the second; as it ascendeth it becommeth fleshy and is mingled with the former before at his insertion he is implanted into the nowle. The third [tab. 11. from E to F] is situated in the side and springeth partly fleshy partly neruous from the transuerse or ouerthwart processes of the second and first racke-bones of the Chest. *Platerus* addeth from the five lower of the necke. From thence it proceedeth obliquely outward and becommeth fleshy and broad and is inserted into the Nowle at the root of the Mammillary proceffe, but it is not of the same forme in Dogs and Apes. These muscles if they worke together, they extend the head directly drawing it backward, if eyther of them mooue alone, the head is drawne round to one side. *Archangelus* addeth a little also backward by the right, and forward by the left.

The third paire (which *Vesalius* reckoneth for the fourth part of the second Muscle, being deceyued faith *Falopius* by certaine fibres of one of the muscles of the backe which grow to the beginning of it) [tab. 11. GG] is not very great or thicke & is situated vnder the second paire. They arise Neruous from the transuerse processes of the six first rack-bones of the necke; sometimes also but rarely from the five vppermost of the chest; then it becommeth fleshy and stretcheth obliquely vpward and inward, their Fibres reaching to the spines of the bones, and at their insertion which is to the backward roote of the Mammillary proceffe they end Neruous, receiuing an additament or encrease by two small portions arising from the transuerse proceffe of the first racke-bone of the Necke. Their vse is when they moue together to lead the head lightly backward; if either of them worke alone it draweth it backward to one side.

The fourth paire which are called *Recti maiores* the greater right Muscles [table 12. A B] are yet small, fleshy and slender, arising from the top or height of the spine of the second bone of the necke at [E] where they touch one another, but presently part againe and ascend both vpward and end round in the middle of the Nowle or *Occipitum*.

The fift paire called *Recti Minores*, the lesser right muscles [tab. 12. F G] are situated vnder the former and are like them in substance, forme and progresse. They arise close together from the backe part of the first *Vertebra* where the bone should haue ended in a spine but that spine is wanting, because it would haue offended those muscles: presently after their originall they part and ascend vpward, and on eyther side are implanted round into the middle of the Nowle. The two last paires haue one and the same vse, which is if they mooue together directly to extend the head drawing it backward, but if one of them mooue alone, it mooueth it circularly to one side. Now the reason why there are so many muscles appointed to draw the head backward, is because the forepart of the head by reason of the face and neather Iaw is very heauy and weighty, and therefore needed more helpe to retract it, whereas it noddeth forward very easily.

The sixt paire, according to *Vesalius* the fift, are called *Obliqui superiores* the Vpper oblique muscles; [tab. 12. H I] they are seated vnder the right, and are like them in forme and substance: smal they are and arise out of the middle of the Nowle at the vtter side of the fourth paire, thence they descend downward, & are ouerthwartly inserted into the top [at D] of the transuerse processes of the first rack-bone of the Necke, the right muscle into the right proceffe, and the left into the left. Their vse is, if they both mooue, to nodde gently and directly backward, if one alone then the head enclineth backward to that side the muscle is on which mooueth.

The seauenth paire, according to *Vesalius* the sixt, according to *Columbus* the fift, are called *Obliqui inferiores*, the lower oblique muscles. [tab. 12. K L] They arise from the spine

δ, His originall.

ε, His end.

ζ, the fourth muscle of the backe called *Semispinatus*.

η, His vpper end vnder the 4. Muscle of the necke

of the second rack-bone of the necke [from B to D] and passing obliquely vpward are implanted into the transuerse processes of the first *Vertebra*. These, as also the oblique superiors are longish, round and fleshy (farre larger in Dogs and Apes then in men) and do make a triangle of equall sides.

The vse of this seuenth paire is semicircularly to mooue the head (for it hath not perfect circular motion) with the second *Vertebra* vpon the first when one mooueth alone. If they both mooue, either they keepe the head steddy as *Falopius* in his obseruations conceiueth, or else do draw it backward a very little, even so much as may rather giue rest to the second rack-bone then motion; for the motion and rest of the head followeth the motion or rest of that second *vertebra* or rack-bone.

The 8. paire.

The eight paire which is the seuenth according to *Vesalius* are called *Mastoides* [table 6. fig. 2, R. the latter tab. 7. fig. 2. B] They are seated forward toward the face next vnder a membranous and broad muscle in the necke; [tab. 6. fig. 1. r] strong they are, long and round, and

Situation.

do appeare in leane carkasses vnder the skin before it be dissected, yea in living bodies, and these are they which the Ancients so diligently obserued in their Coynes. They arise from the middest of the top of the brest-bone [at p] and from a part of the *Clauicle* where it approacheth neere the brest-bone [at σ] to be articulated with it: at which their originall they are Nervous and broad, but more nervous where they arise from the brest-bone, and

Originall.

from thence ascend obliquely vpward and become fleshy and thicke, and are obliquely inserted with a fleshy and thicke end into the Mammillary processe (which they compasse with their largenesse) and into the backpart of the *Nowle*. [tab. 6. figure 2. the vpper T] And this muscle by reason of his double originall betweene which there is a kinde of hollownes [betweene p and σ f 2.] because it seemeth as if it might be diuided into two, some

Infertion.

do diuide it into many. Their vse is if they moue together to bend the head forward into the bosome as when we nodde, either carrying the necke stiffe or inclining it: if one of them onely worke then the head is mooued forward to the left side if it be the right Muscle, and to the right side if it be the left, which motion we may plainly perceiue in guiding a horses necke with the reines. This paire with the second paire of the bone *Hyois* [tab. 6. fig. 2. γ γ] make a crosse in the Necke.

Vse.

The

The 9. paire [*tab. 13. at the side of AB*] is added by *Falopius*, described in some sort by *Galen*, and is situated vnder the gullet in the forepart of the necke & it is a diuerse muscle from the first paire of the necke [*tab. 13. AB*] to which it adioyneth. It ariseth neruous from the Ligaments of the rack-bones of the necke, which Ligaments or Chords doe arise from al the transuerse proceffes of the rack-bones of the necke, especially from the 7, 6, 5, 4, & 3.

After his originall this Muscle groweth somewhat fleshy, and ascending vpward is inserted with a fleshy end into the Basis of the head betwixt the two proceffes where the head is articulated with the first *vertebra*. His vse is when we nod to bend the head somewhat forward. And thus much of the Muscles of the Head.

CHAP. XXII.

Of the Muscles of the Necke.

THe Muscles which mooue the necke primarily, and secondarily or by accident the Head, are on either side three, or foure if you adde the *Scaleni*, which we account rather among the muscles of the Chest: these are situated vnder the Muscles of the Head, some of them before at the sides of the necke, some of them behinde.

These motions of the Necke are to bend forward, to extend backward, to incline to the sides and to turne round as it were: but there are more Muscles to draw it backward then forward, because the labour is greater by reason of the waight of the Necke and the Head.

The first paire are the two Long Muscles [*tab. 13. AB*] which are seated in the forepart of the Necke vnder the gullet, wherefore they are also called the *vnder Gullet-lurkers*. These

The motions
of the necke.

d, the holy bone. *ooo*, the holes of the holy bone out of which the nerues do yssue.

e, A portion of the fift muscle of the thigh arising from the share-bone.

f, the share-bone bared.

g, the ninth muscle of the thigh or the first *circumflexor*.

arise with a fleshy thin and sharpe beginning from the body of the fifth racke bone of the chest where the rib is articulated to it, and ascending broader doe grow to the five vpper *vertebra* of the chest and all of the necke. They also as they ascend by degrees do approach or incline one to the other, yet so as they leaue the middle part where the gullet descendeth vncouered, but at their determination they ioyne in a neruous and sharpe Tendon, and are implanted into the bunching proceſſe of the first racke bone: sometimes but rarely they are implanted and that obscurely into the nowle, euen at the great perforation thereof; so that it may seeme the nowle is turned by them. Their vse is by their proper motion when they worke together, to bend the necke directly forward and withall to incline the head, but if one of them moue alone, then is the necke inclined forward into that side which is contracted, or on which the muscle moueth.

The 2. paire. The second paire make those which are called *Scaleni* and are accounted as the 8. muscle of the Chest. [tab. 13, CC, tab. 12, A] Their situation is on the sides of the necke rather before then behinde. They are esteemed to arise fleshy and large from the first rib, and to bee inserted into all the transuerſe proceſſes of the rack-bones of the necke, excepting sometimes the first & the second; from which we thinke with *Falopius* they haue their originall. Their vse is also thought to be, to bend the necke forward as doth the first paire: this one thing is peculiar to them saith *Vesalius*, and *Platerus* consenteth, that they haue a through-passage by which the veines and arteries do run into the arme.

The 3. paire. The third paire (which *Vesalius* maketh the third paire of the backe, but *Platerus* the third paire of the necke) are called *Transuersales*, or the two ouerthwart muscles. [table 11, E] Their seate is in the backe, and they arise from the rootes of the transuerſe proceſſes of the fixe vppermost racke-bones of the Chest, from whence by degrees they become stronger and thicker, and are inserted into the outside of the transuerſe proceſſes of all the bones of the necke, but more rarely into the first. Sometimes they haue two other originals, one from the second paire of muscles of the backe, the other from the fift paire of the Chest, which together make vp these muscles. Their vse is, if they worke together to extend directly backward, if one of them alone the motion is not direct but oblique. Also between these do passe those nerues of the marrow of the backe which come out of the racke-bones of the necke.

The 4. paire. The fourth paire called *Spinati* because they are seated among the spines of the *vertebra* [tab. 12, H] do occupy or take vp the whole necke. They arise from the rootes of the spines of the seauen vppermost bones of the chest; and after they haue attained the lowermost *vertebra* of the necke, they gather a broader originall therefrom, and yet with the fibres which they receiued from the *vertebra* of the chest they indeuour an obscure insertion into the spine of the lowermost *vertebra*; but they grow more strongly to the rest of the spines of the necke bones, and draw new beginnings from the rootes of their transuerſe proceſſes euen to the second *vertebra*, and insert the fibres they receiue from them into the spine of the rackebone next aboue, till they haue implanted themselves ouer all the spine of that second racke bone of the necke, where the right is ioyned with the left: and indeede they ioyne all along their progresse vp the necke sauing where the spines of the bones peepe vp betweene them and seuer them a little asunder. Their fibres at their originall are outward, but as they ascend they incline inward.

Their quaint passages.

Their vse is if they worke together, to extend the necke, drawing it directly backward, but if one of them moue alone then is their motion not direct but oblique to the side contracted, or on which the muscle moueth. And so much of the muscles of the necke.

CHAP. XXIII.

Of the muscles of the Shoulder-blade called *Omo-plata* or *Scapula*.

Why the shoulder-blade doth not moue round.

THe Shoulder-blade hath foure right motions, forward, backward, vpward, downeward: for which it is provided of foure muscles, *Galen* saith seuen, and *Sylvius* reckons five, but all the rest agree in foure, for it is not moued round, for then it could not so firmly hold the shoulder bone; and besides the clauicles being fastned vnto it do keepe it from turning.

The 1. muscle.

The first muscle of the Shoulder-blade is called *Serratus minor* the lesser Saw-muscle, [tab. 14, S] it lieth vnder the pectoral muscle. His originall is broad, and as it were, finger-fanged from the 4. vpper ribs (excepting the first, and very rarely from the sixth) a little before

Table 14. sheweth the body, as it appeareth after the Bowels of the Lower and Middle Bellies are taken away. The right Arme with his Muscle remaineth in his naturall situation, except the Pectorall and the lesser Saw-muscles, which were necessary to be separated and taken away with the Breast-bone. The left Arme is remooved from the side, that the blade of the shoulder and the Clavicle, and those things which ly vnder them might better appeare.

TABVLA XIII.

AA, The first muscle of the cubit called *Biceps*.
B, the second muscle of the cubite in the left arm, called *Brachialis*.
DE, the first paire of muscles of the necke vnder the gullet.
F, the second of the necke arising from the first rib.
GGG, the outward *intercostall* muscles.
HHH, Letters set vpon the ribbes which should haue bene placed vpon the inner *intercostall* muscles.
I, The left clauicle or collar bone remooved from his place and bared.
K, the right clauicle or collar-bone in his own place.
L, the first muscle of the arme called *Pectoralis*, remooved from his originall.
aβγ, the circumscription of this muscle.
δ ε, His tendon and insertion.
M, the second muscle of the arme called *Deltoideus*.
ζ H, his originall and insertion.
N, the same muscle separated & reclined from his originall.
O, the fourth muscle of the Arme called *Rotundus maior*.
Q, the 3. muscle of the cubit or the *extensor*.
R, the 7 of the arme called *Subscapularis*.
υ, His insertion into the arme.
ξ, the tendon of the third muscle of the arme called *Latissimus*.
S, the first muscle of the shoulder-blade called *Serratus minor*, cleuated from his implantation.
TT, the 7. muscle of the thigh called *Iliacus internus*.

T, the first muscle of the Chest called *Subclavius*. **ZZ**, the 2. muscle of the Chest called *Serratus maior*. **22**, the first muscle of the backe called *quadratus*. **Ω**, the round *Pronator* or incliner of the *Radius* or wand. **α α**, the first bender of the Leg. **β β**, the 2. bender of the Leg. **σ σ**, the first paire of benders of the thigh called *Lumbales*, whose head is marked with **σ** and his tendon with **β**. **υ υ**, the third paire of benders of the thigh. **φ φ**, Paires of nerues which goe vnto the thigh. **π**, the Holy bone.

fore they end into their gristles; that his originall might be the firmer: & ascending obliquely vpward, it groweth fleshy and neare the ioynt narrow, and hauing fashioned the figure of a Triangle is inserted with a tendon partly fleshy partly nervous, into the shoulder-blade neare the inner proceffe called *coracoides*. His vse is to bend the shoulder-blade forward to the Chest; for if his vpper fibres be contracted it moueth it to the brest higher, if his lower, lower; if his middle fibres, then directly or in a straight line.

The second is called *Cucullaris* or the Monkes-hood [tab. 15. T] because with his other companion it couereth the backe as a hood doeth, or as a countrey wiues broad white kerchiefe, *Galen* calleth it *Trapezius* or the Table-muscle. His originall is fleshy and thinne, and transuerse or rather oblique from the Nowle; [from **σ** to **α**] but membranous and broad from the toppe of the spines of the necke even vnto the height of the Chest: [from **σ** to **π**] from thence it is straightned as it passeth toward the shoulder-blade, and is implanted fleshy and sinnewy into the spine of the blade, the top of the shoulder-bone and the middle almost of his Basis, and into the broader part of the *Clavicle*. [τ υ] Where it looketh toward the necke of the blade, you shall meete with a membranous and nervous semicircle [φ] ordained haply least it should too straightly presse the muscle which sitteth vpon the gibbous part of the shoulder-blade. [A]

TABVLA XV.

Sheweth the muscles on the backside of the body.

- A, A part of the 1. muscle of the cubit called *biceps*.
 B, The vpper and viter part of the second muscle of the cubit called *Brachiam*.
 C, The third muscle of the cubite.
 D, The fourth muscle of the cubite.
 K, The insertion of the seventh muscle of the head called *Mastoides* into the mammillary proceffe.
 M M, The second muscle of the arme called *Deltoids*.
 N N, The third muscle of the arme called *Latissimus* circumscribed with $\lambda \mu$, a part of whose tendon at the insertion in the former table is noted with ξ .
 T, The vpper part of the Cowle muscle.
 O O, The fourth muscle of the arme called *Rotundus maior*.
 P P, The fifth of the arme called *super-scapularis inferior*.
 II, The first part of the *supinator* of the *Radius* or wand.
 *, A portion of the oblique descendent muscle of the *Abdomen*.
 T, The second muscle of the shoulder blade called *Cucullaris*.
 $\sigma \pi$, The originall of this muscle from the nowle.
 $\rho \sigma$, From the spines of eight rack-bones of the chest.
 From σ to π from the spines of the necke.
 $\tau \nu$, His insertion into the spine of the blade, into the arme and clauicle.
 φ , His membranous semicircle.
 β , The fift muscle of the leg called *Semimembranosus*.
 χ , The fourth muscle of the leg called *biceps*.
 $\delta \epsilon$, The 3. muscle of the leg called *Seminervosus*.
 ζ , The fleshy part of the first muscle of the leg or of the first extender.
 η , The seventh muscle of the leg, or the second extender covered ouer with the membranous tendon of the sixt.
 $\mu \mu$, The first muscle of the thigh, or the first author of the buttocks.
 $i k l m n$, His originall at $i k l$, his insertion at $m n$.
 ν , the 2. muscle of the thigh hidden almost by the former.
 ρ , A part of the fifth muscle of the thigh called *triceps*.

The 5. lines
of this muscle.

It is circumscribed or limited with five lines; the first is ouerthwart at the nowle, [from σ to π] the second runneth straight along the spines, [from σ to ρ] two are oblique, one of them from the eare to the canell bone, the other from the end of the straight line which I sayd did run along the spines. [tab. 15, from τ to ϵ] The fifth & last is transuerse in the middle of the muscle where it is inserted into the spine of the blade, the top of the shoulder and the broad part of the cannell bone or clauicle. Wherefore this second muscle as well by reason of his diuers originall as also his seuerall kindes of fibres, moueth the shoulder-blade diuersly. For when the fibres which run along obliquely downward from the nowle and the spine of the necke are retracted, that is, when the vpper part of the muscle is retracted [at T] then is the shoulder blade lift obliquely vpperward: but when the fibres which proceed from the spines of the chest obliquely vpperward are gathered into themselves, that is, when the lower part is crumpled together [tab. 15, Δ] then the blade is drawne downward, but if the middle or the transuerse fibres be contracted [at σ] then the blade is directly led to the backe.

The third
muscle.

The third muscle is called *Rhomboides*, that is, the square muscle, [tab. 26, ν] It is situated vnder the former, thin it is, broad and foure cornered, and groweth fleshy from the spine of the three lower rack-bones of the necke and the three vpper of the chest, and his fibres run oblique from the backe to the bottome or foundation of the blade, into which basis of the blade it is also being-broad, fleshily inserted after the length of it, and draweth it vpperward somewhat and backward, and coucheth it to the backe.

The

Tab. 16. sheweth some Muscles of the Head and the Chest, the Cowle-Muscle being taken away, as also of the Blade and of the Arme.

TABVLA. XVI.

- A, The prominent part of the fourth muscle of the Chest called *seratus posticus superior*.
- A, the first muscle of the head called *splenius*.
- E E, the insertion of the second muscle of the head called *Complanatus*.
- I, the collar bone bared.
- M, the backpart of the second muscle of the arme called *Deltoid*.
- z, His backward originall.
- h, His implantation into the arme.
- N N, the fourth muscle of the arme called *Latissimus*.
- S u, His originall from the spiaes of the racke-bones, and from the holy bone.
- π, the connexion of this muscle with the hanch-bone which is led in the inside from π to π.
- ω, the place where it lieth vpon the lower angle of the Blad of the shoulder-blade.
- O, the 4. muscle of the arme called *Rotundus maior*.
- c, Some muscles of the backe do here offer themselves.
- P, the fift muscle of the arme called *superfascularis inferior*.
- Q, the sixt muscle of the arme called *Superfascularis Superior*.
- S, the beginning of the third muscle of the arme called *Latissimus*.
- X, the third Muscle of the Blade called *Rhomboides*.
- o X, His originall from the spines of the rackebones.
- 4 ω, His insertion into the Basis of the shoulder-blade.
- x, the 4. muscle of the Blade called *Leuator*.
- * A part of the oblique descent muscle of the Abdomen.

The other Letters in the thigh haue the same reference which they had in the former Table.

The fourth Muscle is called *Leuator* or the Heauer [table 16. at X] and is situated about the clauicle. His originall is very diuerse (whence it is that some haue made diuerse Muscles of it) from the transuerse processes of the racke-bones of the necke, and commonly from the 1, 3, 4, 5. but rarely from the second. But these diuers originals do soone grow into one, and passing downe do make a strong and fleshy muscle, which is inserted with a broad and fleshy tendon (his Fibres being all of them almost right, few oblique) to the vpper and inner angle of the shoulder-blade. His vse is to draw the blade vpward toward the forepart and to the sides of the necke.

These are the Muscles by which the blade is moued originally, the arme by accident, as also the blade is moued by accident by the Muscles of the arme, for when they draw the arme, they draw the blade also by consecution which is annexed thereto.

CHAP. XXIII.

Of the Muscles of the arme.

He Ancients called all that the Hand which is betwixt the top of the Shoulder and the Fingers. The first part therefore of the whole Hand is called in Latine *Humerus*, which we translate the Arme, and it reacheth from the top of the shoulder to the next loynt or bending of the Cubit, which we call the Elbow. The *Gracians* call this part *Brachion*, and the cavity which is vnder the loynt at the shoulder is called *Ala* the *Arme-pit*. The toppe iust against the pitte is properly called the *Shoulder*. This member that it may

The particular parts of the arme.

may more easily be moued euery way is articulated with the shoulder blade by *Enarthrosis* (which kind of articulation we shall make plaine in the Booke of Bones) and moued by Muscles.

The voluntary motions of the Arme are five: forward to the Breast, backward toward the backe, vppward toward the necke and the head, downward to the sides of the Chest, and finally, it is moued in compasse or circumuerted. For all these motions there are seauen Muscles: some of which as the first and the third are fastned to the Chest, the rest grow vnto the shoulder-blade.

All these we will describe according to the order of dissection: yet first we giue you to vnderstand that *Galen* in his Booke *de dissect. Muscul.* and the 18. Chap. reckoneth eleuen, three ascending from the Breast vnto the Arme, two from the regions of the hands, and five from the shoulder-blade, the 11. seareth vpon the *Epomis*. *Vesalius*, *Columbus*, *Archangelus* and *Falopius* in his institutions reckon seauen; the same *Falopius* in his obseruations and *Laurentius* account eight. But we hold vs to seauen according to the Authors aboue named and *Bashine* with them.

The first

The first is called *Pectoralis* the Pectoral Muscle [tab. 17. L.] so named from his situation, because it occupieth the forepart of the Chest. It is a large muscle and fleshy, and because of his originall it consisteth of vnequall sides: whence it was that it is called by *Laurentius* *Pentagonus* or *quingulaterus* as hauing five sides. It groweth almost to the whole Breast-bone & the gristle thereto annexed, to the middle of the clauicle where it is nearest to the Breast-bone and to the gristles of the 6, 7, and 8. ribs: so as it may seeme (to him that takes but an ouert view thereof) to be compounded of many muscles. [tab. 17. & by doe circumscribe it, and table 18. figure 1.] Yea *Galen* himselfe in the 18. Chap. of his Booke *de dissectione Musculorum*, and the 13. of the 13. *de vsu partium*, thinketh it may be diuided into three or foure, but *Columbus* reprehendeth him for it. Notwithstanding for *Galen* we may say, that from the clauicles it ariseth with a fleshy originall, and from the middle of the Breast-bone and the gristles of the ribs which are membranous and neruous. Afterward by degrees it becommeth thicker and more fleshy, and is againe by degrees straightned and gathered narrow, reseruing in the vpper part by reason of the short course of his fibres a fleshy body, but below long before his insertion it appeareth liuid and neruous, and the depth and bottome thereof is much slenderer then the vpper part.

His originall diuers.

[Tab. 17. is the same with Tab. 14. of this booke.]

Implantation.

At length it is implanted with a short but broad sinewy and strong tendon [tab. 17. and tab. 18. figure 1, and 2. S.] to the bone of the arme lengthwise a little below the inner head thereof, betwixt the muscle called *Deltoides* and that which is called *Biceps*. [tab. 17. and tab. 18. fig. 1. M A] But at his implantation he bendeth forwards as if his tendon were reduplicated. And truly in some men a portion of it is found to grow into a kind of point, immitating a peculiar muscle, whereas indeed it is a part of this muscle we now entreat of. Albeit *Columbus* thinketh that *Galen* in the 18. Chap. of his Booke *de dissect. Muscul.* describeth this production for a particular muscle.

His use.

This *Pectorall* muscle by reason of his diuers originall hath also diuers fibres: some run obliquely downward from aboue, others obliquely vppward from below: in so much that a little before the muscle produceth his tendon these fibres seeme to intersect one another in a decussation, and yet all of them concur together into one angle to forme the tendon. This variety of fibres maketh the different motions which this muscle performeth.

The office of this muscle is when it contracteth equally all his fibres, especially the middlemost in euery part of his body, to moue the arme equally and directly forward, inclining on neither hand, and to leade it to the breast. But if all the fibres be not equally contracted, then is it led indeed to the Breast but obliquely, more vppward or more downward as the different fibres are contracted.

The second

His name.
What *Epomis* is.

The second Muscle of the arme is, called *Deltoides*, from the forme of the Letter Δ : [tab. 17. tab. 18. figure 1, 2, 4. M] some call it *Epomis*, because it lyeth vnder the lesser head of the arme which is properly called *Epomis* by *Hippocrates*, *Galen*, *Ruffus* and *Oribasius*, as *Falopius* in his obseruations hath very well obserued, thereby clearing no small Controuersie in our Art about the acception of the word *Epomis* in *Hippocrates* and the Ancients. Some call it *Humeralis* or the Arme-muscle by a kinde of excellency.

It is fleshy and triangular, or *tetragonall* sayeth *Archangelus*, arising from the middlest of the clauicle where it regardeth the shoulder-blade, from the top of the arme where it

is

fig. 1. 3.] But you must not conceiue that it taketh his Originall from the ground or soale of these bones, but from a certaine prominence or thicke line bearing out from them:

Note moreover, that in the originall this Muscle is broade (as being compounded of diuers yet continued beginnings like so many seuerall muscles) and Nervous: (tendinous saith *Columbus*) but presently becommeth fleshy and thicke, and so remaineth till by degrees it be angustated or straightned into the top or corner of the triangle, and so at length endeth into a strong Tendon which is partly fleshy, to wit, on the outside, and partly Nervous, to wit, on the inside, appearing in our dissections to ly not perfectly ouerthwart yet more then oblique. It embraceth or compasseth the middle thicknes of the arme, and is inserted in the midst thereof vnder the necke of it. [tab. 18. fig. 2. 8]

This Muscle also hath Fibres somewhat diuers, those of the fore part run obliquely downward and backward, those of the backe part run obliquely forward. And some of these do appeare to be a little implicated or entangled one within another: but the middle Fibres tend directly downward. Wherefore when the anterior Fibres are contracted, the arme is lifted vpward and forward towards the face, when the backward Fibres are contracted, then is the arme lifted backward toward the Nowle, but when the middle Fibres are equally contracted then is the arme eleuated directly vpward.

The third muscle of the arme is called *Latissimus*, that is, the broad muscle, & *Aniscliptor* the *Pruritan* muscle, [table 15, and 16, N. table 25. sheweth it separated] because it reacheth neere to the buttocks, for together with his fellow it couereth almost the whole backe, and therefore may well be called (saith *Bauhine*) *Dorsalis Maximus*, the Greatest Muscle of the backe. It ariseth with a membranous and broad beginning from the tops of the spines of the Rack-bones which are betwixt the sixt vertebra of the Chest, and the middle of the Holy-bone, [tab. 16. 5. 4] as also from the vpper part of the haunch-bone: thence ascending, when it attaineth to that part of the backe where the ribs swell out backward it becommeth more fleshy, and climbing over the lower angle of the basis of the shoulder-blade it groweth narrower, and is inserted below the vpper head of the arme lengthwise on the inside betwixt the Pectorall and the Round Muscles; his tendon being strong and short, yet broad and as it were reflected. For betwixt the tendons of those two forenamed muscles there is a distance left for this insertion, in which place also is the cavity of the arme-pit made by the Muscle and the Pectorall.

The figure of it is Triangular, for it hath three vnequall Angles, two long and one short. The sharpest is that which groweth from the Holy-bone: the next is at the Chest where the Muscle yssueth from the Ridge of the Rackes. The third is at the arme and endeth into the tendon. Moreover, this Muscle when it attaineth to the lower angle of the shoulder-blade, receiueh sometimes therefrom many fleshy Fibres, as *Galen* well obserued in his Anatomical Administrations and in the 12. Chapter of his 13. Book *de vsu partium*, which Fibres do represent a new but small Originall. *Vesalius* denies this and holdeth it not to touch the shoulder-blade, but by the interuening of Muscles which arise therefrom, and that it groweth not at all to the bone; but as he reproceth *Galen*, so *Falopius* in his Institutions reprooueth him, affirming that in all the bodies that euer he made dissection of he found this Muscle fastened to the blade.

Bauhine rendreth a reason. It groweth (saith he) with certain Fibres to the basis of the shoulder-blade, least when the blade is mooued it should ride over the muscle, for the se Fibres as it were Ligaments do hold the Muscle and the blade together. *Galen* also in the 5. Chap. of his 13. Booke *de vsu partium* saith, that by the benefit of this adhesion or cleauing the blade also is mooued downward by this third muscle. Notwithstanding, *Falopius* dares not for certaine affirme that it doth mooue the blade, but that it conferreth something to his motion he is very confident against *Vesalius*.

The Fibres also of this Muscle do differ according to the inequality of the ribs; for some are long and lesse oblique, others are short and more transuerse. Wherefore, as these fibres are contracted into themselves, the arme is more or lesse retracted downeward and depressed toward the backe, sometimes higher, sometimes lower.

The fourth Muscle is called *Rotundus maior*, almost by common consent of all Anatomists, The greater round Muscle. [tab. 10, 11, 14, 15, 16, 25. and Tab. 12. fig. 4. 0] *Platerus* also calleth it the *Longer transuerse Muscle* because it is seated obliquely on the backe side vnder the arme-hole. It is fleshy, thicke and rounder then all the rest. His Originall is but small yet continually fleshy which originall it taketh from the lower ribbe or ridge of the

Originall.

p 4, The lower. The first of those muscles which extend the 4. fingers.

contrary to the second muscle called *Deltoides*. *Galen* reckons it among the *Turners* of the arme, for (saith he) it turneth the arme outward: *Vesalius* reprehends him and sayeth that it applyeth the arme directly to the backe. But *Archangelus* beside that direct motion, ascribeth vnto it an outward motion and a little inward. *Laurentius* would haue his motion to be onely oblique.

At the lower part of this Muscle or at the lower rib or ridge of the blade we finde a distinct portion implanted with a neruous termination neare the insertion of the 5. muscle which *Falopius* maketh the eight muscle of the arme, which (saith he) is manifestly separated from all the rest, as I haue found in all my Dissections, and I wonder much (sayeth he) that our late Anatomists haue ouer-skippt this muscle, which is of great moment as being together with the seauenth the authour of the same motion, especially because *Galen* obserued it in Apes in the 18. chapter of his Booke *de dissect. muscul.* and in the first chapter of the 5. Booke of his Anatomicall Administrations.

The first Muscle of the Arme is called *Superfascularis inferior*, the lower Blade-rider, [tab. 15. 16. 25. P. tab. 18. fig. 4. P.] It couereth all the outward and gibbous part of the blade which is vnder his spine and beareth the forme thereof. It ariseth fleshy from the Basis of the blade below the spine, becomming narrow as the blade-bone groweth narrow, and is inserted obscurely semicircular wise to the outside of the Ligament of the arme which holdeth the ioynt.

The vse of it is (saith *Bauhine*) to leade the arme in compasse outward, *Archangelus* addeth vpward also, *Laurentius* saith it retracteth it backward.

The sixt Muscle called *Superfascularis superior* or the vpper Blade-rider, is also called *Rundus minor* the Lesser round Muscle. [tab. 10. 11. 15. 16. 25. Q.] It is seated about the Arme-hole and filleth all the cavity which is betwixt the vpper ribbe or ridge of the blade and the spine of the same; from which it ariseth fleshy, long and hauing long fibres, for it proceedeth from that Basis of the blade-bone to which it groweth very strongly, and when it attayneth to the vpper part of the neck of the Blade, it runneth vnder a transuerse Ligament which coupleth the arme to the inner proceffe of the blade, and with a broad and strong Tendon riding ouer the ioynt is obliquely inserted to the Ligament thereof.

The vse of this Muscle saith *Bauhine* is the same with that which went before and which followeth after, *Archangelus* sayth it leadeh the Arme vpward and backward, *Laurentius* backward onely, *Vesalius* doeth not thinke that *Galen* makes any mention of this Muscle, vnlesse haply it be reckoned among the Heauers of the Arme, for none of his descriptions agree thereto, although hee make light mention of a muscle riding ouer the vpper rib of the blade.

The seauenth muscle called *Subfascularis* the Blade-lurker, or *Inmersus* the drowned Muscle, [Tab. 7. R.] is seated betwixt the Blade-bone and the ribs. Very fleshy it is and continuall with the former on the vpper side, occupying the inner hollow part of the Blade-bone, from whence it ariseth. It is like the Blade triangular, straitned by degrees at the inside of the ioynt, and with a broad Tendon is Semicircularly inserted into the inside of the arme, (*Laurentius* sayth into the necke and head of the arme) so that the Tendons of the 3. muscles which leade the arme about do orbicularly incompasse the whole ligament of the ioynt.

His vse is to leade about the Arme inward, *Galen* in the 18. chapter of his Booke *de dissect. muscul.* sayeth that it circumuerteth the head of the arme backward: *Archangelus* that it moued the arme vpward and inward, *Laurentius* that this together with the lesser round muscle and that which is called *Infra spinatus* doe moue the arme semicircularly backward, for (sayth he) a perfect circular motion the arme hath not from any peculiar muscle, but by the successive working of them all, for that which is circular is compounded of all the right and all the oblique.

That notable musculous portion arising from the proceffe of the Blade-bone which is like an anchor, and inserted into the arme, *Arantius* and *Placentinus* doe esteeme to be a muscle of the arme; others account it for the first muscle of the cubit. His vse say they is to leade the arme to the proceffe of the Blade-bone, and indeede the motions of the arme and cubit are neare of kin, for when the cubit is bent in the Elbow, it is most what necessary that the arme also should bee lifted vp, as we may obserue in our selues; and so much of the muscles of the Arme.

CHAP. XXV.

Of the Muscles of the Cubit.

The bones of
the Cubite.

THe Cubit which is the second part of the Hande in the large acceptation, consisteth of two bones, the first is called *Cubitus* or *Vlna*, the Cubit or the Ell, and we retaineth that name when we call the place where it is bent the *Elbow*. The second bone is called *Radius* or the *Wand*. These bones haue diuers motions, & therefore the Muscles of the Ell and the Wand are diuers. The Cubit or Ell hath two motions, for it is bent and extended directly. *Galen* attributeth also to it an oblique motion, which *Columbus* saith is nearer to be found in a man: the *Radius* or wand being mooued turnes the hand vpward and downeward: First we will speake of the motions of the Cubit which are performed by the helpe of foure Muscles, some say five, and these are called the muscles of the Cubit, not because they are seated in the Cubit, but because they mooue it. For they arise from the arme and the blade, and take vp the roome along the arme; the two *Benders*, the inside or fore-side, and the two or three extenders the outside or the backside. But these Muscles which are seated in the cubit it selfe do serue to mooue cyther the Wand, or the Wrist, or the fingers.

The 1 Bender

The first *Bender* is called *Biceps* [tab. 18. fig. 1, 2, 3, and tab. 19. fig. 1, and 2, A] or the double-headed muscle, because it hath a double beginning and these very strong standing off one from another to giue way to the Nerue of the arme and the insertion of the muscles of the same. These originals doe arise from the shoulder-blade, but are covered by the second muscle of the arme called *Deltoides*. [tab. 18. fig. 1 M, at fig. 3, N, they are vncouered]

The situation of this Muscle is on the inside of the arme, and in those bodies that are fleshy or brawny it may be perceiued vnder the skin before the dissection. Of these two originals the one is outward [tab. 19. fig. 1, n] which is neruous and round, arising out of the vpper brow of the cup of the shoulder-blade, and is deriued vnder the Ligaments of the ioynt of the arme, and aboue the head of the same through a fissure or cleft made of purpose for this vse.

The other originall [tab. 19. fig. 1, o] is partly Neruous, partly fleshy, broader also then the other arising from the proesse of the blade-bone which is like vnto an Anchor, and led aboue the head of the arme, a little vnder which head it is vnited with the former [tab. 19. fig. 1, and 2, p] and so they make one thicke, strong liuid muscle round and furnished with right fibres.

A fleshy portion
accounted
for a particular
muscle.

A fleshy portion of this muscle is inserted into the middle of the Hand, where the bone hath a private asperity by which it is lift vp. This portion (sayth *Columbus*) to a man that is not sharpe sighted seemeth a distinct muscle drawing the arme to the brest, of which portion also *Vesalius* and *Laurentius* haue made mention, but not *Falopius* or *Archangelus*, but *Arantius* somewhat boldly propoundeth it for the eight muscle of the arme: and indeede departing from the arme and climbing ouer to another muscle it beareth the forme of a round and fleshy muscle, and a little aboue the ioynt of the cubit becomming more sinnewy it endeth into a strong, thicke, round and neruous Tendon, and being moderately dilated is inserted into an inward eminence and protuberation of the *Radius* or wand, created onely for the insertion thereof. It groweth also somewhat to the ligament of the ioynt. [tab. 19. fig. 1, g] This Muscle as also the second hath right fibres, wherefore with the second it benderth the cubit straight inward.

The 2 Bender

The second *Bender* is called *Brachialis* the muscle of the arme [tab. 18. fig. 2, 3, 4. tab. 19. fig. 1, 2, 3 B]. It lyeth vnder the former, is shorter than it and wholly fleshy, and embraceth very closely the lower and middle part of the length of the arme vnto which also it groweth. It ariseth from the bone of the arme in that place where the Muscles of the arme are inserted about the middle of the length thereof on the outside. His beginning is fleshy and twofold, [tab. 21. fig. 2, 3, V] and in the middle resembleth an obtuse angle. Presently after it becometh thicker and groweth strongly to the arme, and descending downeward fleshily couereth the fore-side of the Elbow representing a little hillocke, and is strangely infixed or inserted larger and more fleshy into the forepart of the Cubit or Ell, and the *Radius* or Wand, and the Ligament of the ioynt. [tab. 21. fig. 2, G fig. 3, o] to bend the cubit in a streight line.

The third.

The third muscle of the cubit or the first *Extender* called also the long muscle [tab. 28. fig. 2, 3, 4. tab. 19. fig. 1, 2, 3. and in the other figures at C] runneth fleshy and with right fibres through the backside of the arme. It ariseth with a strong and broad originall, partly neruous and partly fleshy from the lower rib of the blade bone a little vnder his necke, where it hath

l 2, the lower proceffe of the shoulder blade.

n 1, 2, the outward neruous head of the muscle called *Biceps*.

o 1, 2, his neruous head.

p 1, 2, the coition or meeting of these two nerues.

q 1, 2, the tendons of this muscle.

r 2, A part of the *Supinator* or the muscle which bendeth the hand vpwatd where it goeth from the arme vnto the cubit.

s 2, his broad tendon inserted into the appendix of the wand.

t 2, the beginning of the second muscle bending the foure Fingers.

A 1, 2, the *Biceps* or the first muscle of the cubit which hangeth vpon the fourth from his insertion.

B 1, 2, 3, the 2 muscle of the cubit called *Brachians*.

C 1, 2, 3, the 3. muscle of the cubit called *longus*.

E 1, the muscle of the palme of the hand whose broad tendon is at u.

F 1, 2, the first muscle bending the foure Fingers hanging downe in the second Figure.

G 1, 4, the second muscle bending the foure Fingers hanging in the fourth Figure, & sheweth his tendons.

H H 2, the muscles called *Lumbricales*, their insertion at e in the 4. Figure.

f 2, 4, the first of those that bend the thumbe, in the 4. it dependeth from his insertion, and his tendon is at e.

K 1, 2, the second bender of the thumbe.

L 2, 4, the 3. bender of the thumbe.

N 1, the muscle *Deltoideus* inuerted. the vpper N in the third muscle called *Latissimus*, the tendon of the third muscle of the arme. The lower N in the 3. & 4. Figure;

the *Vlna* or Ell without flesh. O, the vpper in the third Figure, the fourth greater round muscle of the arme. o the lower

3, 4, the wand bared. Q 3, the vpper Blade rider whose insertion is at f, 2, K. R, 3, the Blade-lurker whose insertion is

at s. S, the vpper 1, the lesser Saw, whos amplitude whereby it groweth to the ribs. T, the place where it groweth to the

shoulder blade. S the lower 1, 2, the thicke muscle of the little Finger, or the fourth muscle of the extenders. X 1, the

third extending muscle of the thumbe. X 2, the place where the muscle noted with G is diuided into foure fleshy parts:

Y 4, the tendons of the second muscle bending the foure Fingers. y 2, the place where the tendons of the second muscle

doe abide. A 2, the place where the tendons of the first muscle remaine. s 2, the tendons of the first muscle bending the

thumbe inuerted with the muscles in the hand. n 1, 1, the amplitude of the greater Saw whereby it is ioyned to the ribs.

n 2, the muscles of the Fingers growing to the foure tendons of the second muscle in the hand which are called *Lumbricales*

or the worme muscle. i 3, where it groweth to the angle of the shoulderblade, A 1, the beginning and the insertion

of the bender of the wrist. u 1, the tendon of the muscle of the palme of the hand. V 1, the transuerse ligament. T 1, the

muscle called *Ieterossum* or the slender muscle of the little Finger of the palme of the hand. A 1, The first muscle bending

the wrist. O 1 The second muscle bending the wrist here hanging downe. n 1, 2, 3, the first *Supinator* of the *Radius* or

wand, in the 3. Figure hanging from his implantation. q 3, 4, the first *pronator* of the wand or the square muscle.

n 1, 2, 3, 4, The round *Pronator* of the wand. Character 1, 2, 3, in the fourth Figure, the fourth, 5. and 6. muscles bending

the thumbe. * a ligament going betweene the Ell and the Wand.

hath a particularosome or cavity to touch it selfe in, and descending directly downward, it groweth very fleshy to the inside of the arme, or rather it is increased with a fleshy portion [tab. 21. fig. 1, A] bred out of the arme as it were with another original, which is mixed therewith to giue it strength: with which portion being augmented it descendeth directly

Aaaa 2

downe-

Table 19 sheweth the Muscle of the Cubit, the Wand and the Fingers.

TABVL XIX.

FIG. 1.

Augmentation

downward, (that fleshy portion euen to his end growing to the arme) and becomming partly neruous on the outside, partly fleshy on the inside, is inserted into the inner side of the backward proceffe of the Cubit called *Olecranon*; *Archangelus* saith it is inserted into the *exterior* part of the *Radius* where it hath a cauity insculped for it.

Insertion and use.

The use of this muscle is together with that that followeth, directly to extend the Cubit; *Archangelus* addeth that it lifteth it also vpward.

The fourth.

His originall.

Progresse.

Insertion.

Fibres & use.

Munkies.

The actions of the muscles of the cubit.

The fourth muscle or the second *extender* called also the *short* muscle. [Tab. 18, fig. 4. Tab. 20, fig. 1, and 2, D] occupieth the outward part of the back-side of the arme. It ariseth with a neruous originall, (and double saith *Columbus*) from the back-side of the neck of the arme and becomming fleshy before it hath overcome the middest of the length of the arme it is so mingled with the former that euen vnto the insertion it can by no means bee separated therefrom, so that it may seeme to be but one muscle or one body compacted of three muscles, whereas notwithstanding in truth they are two; for this fourth muscle is very strongly inserted [tab. 18, fig. 4, x tab. 20, fig. 1, and 2, x] into the outside of the posterior proceffe of the Cubit, where it is partly fleshy, partly neruous, especially about the point whercon wee leane with ourelbowes, which sinew haply is the reason why at sometimes leaning hard vpon the pitch of the elbow, we find a kind of benumbednes or painefull sensation like the sleepines of the legge to runne along our arme both vpward and downward.

This fourth muscle as the third, hath right fibres, wherefore also it extendeth or stretcheth out the Cubit directly, *Archangelus* addeth also downward. But in dogges and Munkies and other Creatures which rest themselues much vpon their forefeete, there are three very conspicuous extending muscles, beside one very small, found in Munkies (but by *Galen* pretermitted saith *Vesalius*) which runneth from the shoulder-blade to the Cubit or Ell.

So then in these muscles of the Cubit the primary action is euident, which is contraction, & the secondary which is relaxation: when the *bending* muscles are contracted, the *extenders* are relaxed, that so the Cubit might bee inflected with more ease: againe, when the *extenders* are contracted, the *benders* are relaxed that the Cubit might be better stretched out, and both these actions are performed by right motion. By accident also they follow the motion of the arme. Moreouer, the Cubit is moued sidelong and round.

CHAP. XXVI.

Of the Muscles of the Radius or Wand.

The motions of the Radius double.

THE motion of the *Radius* or *Wand* is double, for either it is moued *per se*, of it selfe (the Cubit or Ell being vnmoued) by reason of the ioynt eyther about with the arme, or below with the wrist, or both about and below with the articulation of the Ell; and so the whole hand is mooued eyther downward or vpward, (for the whole hand being sustained almost alone by the *Radius*, hath one and the same motion, and therefore is turned vpward by the assistance of two externall muscles; and downward by two internall, by which also it is turned about.) Or it is mooued by accident with the Ell in a right line when the whole Cubit is bent and extended. There are therefore foure muscles of the *Radius*, two called *Supinators* which turne the palme of the hand vpward, and two call *Pronators* which turne the palme downward.

The first Supinator.

The first *Supinator* which is the second of the *Wand* according to *Vesalius* (who calleth it also the *exterior*) *Pallopius* and *Platerius*, is also by *Laurentius* called *Supinator longior*, [tab. 18, fig. 1, 2, 3, and tab. 20, fig. 1, 2, 4, n] because in respect of his belly it is the longest of all those muscles which run along the Cubit. It ariseth fleshy from the edge of the outward and vpper protuberation of the arme, [tab. 19, fig. 2, f. tab. 20, fig. 4, a] afterward being dilated it is bended vpon the *Wand*, and is inserted, growing broade at his Tendon, into the membranous appendix of the *Radius* toward the inside. [tab. 19, Fig. 2, f. and tab. 20, Fig. 4, b] This Muscle ouer-turnes the lower part of the *Wand*, and so lifts the palme of the hand vpward.

The second.

The second *supinator* which is the shorter [tab. 20, Fig. 1, 3, 4. and tab. 21, Fig. 1, 2] ariseth fleshy. *Platerius* and *Archangelus* say from a strong Ligament which bindeth the cubit

A, 1, 2. A part of the muscle called *Biceps*, or the double-headed muscle.

B, 1, 2, 4. The higher and outward part of the muscle called *Brachialis*.

C, 1, 2, 4. the muscle extending the Cubite from the lower part of the shoulder-blade, others call it the fifth muscle of the Cubit.

D, 1, 2. The short muscle extending the cubit arising from the neck of the arme.

E, 1. The second or the two-horned muscle bending the wrist.

M, 1, 2, 3. The muscle *Deltoides* or the second of the arme.

N, 3, 4. The Ell without flesh.

O, 1, 2. The fourth muscle of the arme called *Rotundus maior*.

O 3, 4. The Wand bare a great way.

P 1, 2, 3. The lower blade rider or the fifth muscle of the arme.

The lower P in the 1 and 2 figure. the first extender of the foure fingers, in the second figure hanging downe, whose originall is at a and tendons at b.

Q 1, 2. the 2 muscle extending the foure fingers; in the 2 Figure hanging downe.

R 2, 3. the third extender of the forefingers in the third Figure hanging downe clouen into 2 parts at op in the 2 Figure.

S, 1, the 4 muscles extending the fore fingers.

T, 1, the vpper, the first muscle extending the thumb.

V, 2, 3. the 2 extending the thumb.

X, 3. The originall of the 3 muscle extending the wrist.

Z, 1, 2, 3, 4. The 4 extender of the thumb.

a, b, 1, 2. The originall of the first extender of the foure Fingers from the protuberation of the arme at a and his tendons at b.

a 4. The originall of the shorter supinator of the

Wand. C 1, the originall of the first extender of the wrist from the vpper protuberation of the arme. C 1, Another part of the long extender of the cubit. d 1, His insertion at the little Finger. e 2. the spine of the blade and the top of the shoulder. f, g, the originall of the Cowle muscle in the hinder part from the spine of the blade. h 2, His insertion. i 2, the membranous Ligament of the Wand, tying the vpper part of the arme. i, k, l, m, n, 2, 3. The vpper part of the second muscle extending the thumb marked with V. inserted into the bone of the wrist at k, l, the lower part divided into two at l, the one vnder the wrist bone that sustaineth the thumb at m, the other inserted into the thumb at n. op 2, The thirde extending muscle noted with R cut into two parts. q 4, the backe of the shoulderblade bare. r 2, the originall of the second extender of the wrist. s, t, 3. the originall of his horned tendon, the insertion. t, x, 1, 2, A place of the Ell without flesh. Δ 1, 2, the first bender of the wrist. Δ 1, 2, the first extender of the wrist. m in the 2 Figure hanging, whose originall is at e and inserted at d. π 1, 2, 4. the first supinator of the wand whose beginning is at e, insertion at β in the 4 Figure. Σ 2, 3, 4. the shorter supinator of the Radius, whose beginning at e his insertion at γ. Ξ 2, 3, 4. the second Muscle extending the wrist. α, β 4, the beginning of the first supinator of the wand from the arme at α, whose insertion at β. γ 4. the insertion of the shorter supinator of the wand. δ, t 4. A place where certaine bofomes are prepared for the transporting of the tendons, and containing a gristle of that place. ζ, 4. Ligaments ioyning the bones of the wrist together. * 3, 4. A Ligament in the middest betwixt the Ell and the Wand.

bit to the arme and from the vpper part of the Radius. *Banvine* from the ioynt which articulath the cubit to the arme, and from the backward proceffe of the Ell [tab. 20. fig. 4. 4] which is called *Olecranon*: from thence it paceth obliquely and is implanted almost into the middest of the wand, to which also it adhereth [tab. 20. fig. 4. 7] and it is on the outside membranous and on the inside fleshy. This muscle turneth the vpper parte of the wand obliquely outward and turneth vp the backpart of the hand.

The first *Pronator* which *Vesalius*, *Fallopianus*, and *Platerus* reckon for the first of the Wand, is called also by *Laurentius*, *Quadratus*, [tab. 19. fig. 3, 4. and tab. 21. fig. 3, 4] because it ariseth fleshy, broad and square, from the lower and inner part of the Ell neare the wrist, and lying ouerthwart on the foreside is inserted with a membranous tendon, *Columbus* and *Archangelus*

The first *Pronator*.

say fleshy) into the inner & lower part of the Wand. His fibres are transuerse and clime vp ouertwhart from the Ell vnto the Wand. It is a large muscle, and incompaseth all that part of the Ell and the Wand which lies directly against the inside of the Cubit. It is square and so long as in the inner Region of the whole Cubit made of the Ell and the Wand. It is also euery way fleshy, and in the middle thicke and bunching, seruing instead of a soft pillow vnder the tendons that runne vnto the fingers. This muscle drawing the lower part of the Wand which is next vnto the wrist inwarde, beareth downe the Wand and the hand fastened thereto into a prone position.

The second *Pronator* which is the third muscle of the Wand according to *Vesalius*, *Fallopianus* and *Platerus*, is by *Laurentius* called *Rotundus*. [tab. 18, fig. 1, 2, 3, and tab. 19, fig. 1, 2, 3, 4. and tab. 21, fig. 1, 2, 3.] It ariseth fleshy from the inner protuberation of the arme and the inner side of the Ell where it is articulated to the arme, or as *Fallopianus* hath it, from the inner ligament of that ioynt: thence it climeth obliquely ouer the inside of the Wand and is implanted with a fleshy insertion about the middle thereof, [tab. 20, fig. 4, 5] from his insertion it runneth out neruous to the very middest of the Wand, and is infixed very strongly with a neruous Tendon to a certaine roughnes that is in the vpper part thereof [tab. 21, fig. 1, 4] As often as this muscle is contracted it leadeth the vpper part of the wand inwarde, and so wresteth the Wand and the whole Hand into a proane and downward position.

CHAP. XXI.

An enumeration of the Muscles of the Hand, properly so called.

Alen considering the admirable frame & structure of the Hand, because it is as he saith the *Instrument of Instruments*, intreateth of it in his first Bookes *de usu partium*. *Columbus* in the last place, because (saith he) the wonderfull and miraculous frame thereof might remaine infixed in our memories; but we will discourse of the Muscles thereof in this place, because we will follow the order of dissection.

Seeing

Seeing therefore that the proper action of the Hand is Apprehension, and Apprehension a Motion depending vpon our will, it was also necessary that the hand should haue muscles which are the instruments of voluntary motion whereby it might bee mooued altogether and euery finger apart.

The muscles
of the hand
double.

The muscles therefore which moue the hand are of two sorts, some haue the guide of the motion of the whole Hand, others moue the Fingers onely. The former are likewise of two sorts; for some doe either bend or extend the Wrist and consequently the Hand with the same motion, others mouing the *Radius* or Wand do together also turne the Hand downward or vpward.

These Muscles are seated vpon the cubit either on the outside or on the inside. Hither also may we referre that Muscle that moueth the skin which is in the palme of the Hand. Those that moue the Fingers doe either bend or extend them or moue them sidelong, that is ioyning them together or parting them asunder.

But because the thumbe (which is called *Pollex*, for that it is æquipollent or æquivalent to the whole Hand) hath in his bending and extending something peculiar to himselfe differing from the same motions in the other foure Fingers, therefore it hath his peculiar Muscles, as also the rest of the Fingers haue theirs, whereof some are seated in the cubit, others in the After-wrist and others in the ball or palme of the Hand.

The reasons
of the motions
from the
articulations.

Againe, because the articulation is diuers in the first ioynts of the five Fingers and is the second of the Thumbe, from that it is in the second and third ioynts of the foure Fingers and the third of the thumbe, because the latter are ioynd by *ginglymos*, the vpper bone receiuing into his bosome the protuberation or swelling of the lower, and the lower bone into his cavity the heads of the vpper: hence it cometh to passe that their motion is onely simple, absolved by extention and flexion without any inclination to either side: but the first bones of the foure fingers and the first of the thumbe being fastned by a firme articulation to the bones with which they are sustayned, are not onely bent and extended, but inclined also to the sides as they are led to-ward or fro-ward the thumbe.

I could busie my selfe and you too in setting downe each Authors diuision of the muscles of the Hand, for euery one almost differs from another, but because the History that followeth dependeth most what vpon *Banbines* relation, therefore wee will remit him that is desirous to know each mans minde vnto their proper discourses, and content our selues with *Banbines* alone.

In the whole summe therefore the Muscles which moue the Hand are forty; foure of the wrist, foure of the wand, of the palme of the hand three sometimes foure, and 29. of the fingers.

40. muscles of
the hand.
How seated.

Some of these Muscles are seated in the cubit because it was very necessary they should be large, and their tendons onely are transmitted vnto the fingers. For if they had beene placed in the Hand they must needs haue increased the bulke thereof to that quantity which would haue beene preiudicall to the vse of so excellent an organ. Notwithstanding some are situated in the Hand.

Of these Muscles there are nine benders: two bend the foure fingers and seauen the Thumbe. The extenders are 20. sixteene extend the 4. fingers, in which number are those foure called *Lumbricales* the Wormy muscles, and those eight called *Interossei*, because they lurke betweene the bones. The other foure extenders doe serue the thumbe which they doe either simply extend or leade to the fingers or from the fingers: the tendons of which foure muscles as *Galen* obserueth in the 17 chapter of his sixt Booke *de vsu partium*, are infixed in the ioynt of the bone that is to be moued. But because in dissection wee meete first with the muscle which is called *Palmaris*, therefore in the first place we will intreat of it.

The vse of the
40. muscles.

CHAP. XXVIII.

Of the Muscle of the Palme, and 2. or 3. other issuing from the fleshy Membrane.

HE Muscle of the palme so called by *Laurentius* and *Banbines* lyeth vpon all the interior Muscles of the Hand. [tab. 22 fig. 1, 2, tab. 23, fig. 1, E] It is seated in the cubit and is neruous and round, arising with a neruous beginning from the sharpe poynt of the inner protuberation of the Arme; leaneth vpon and groweth to the mid-

- His originall.** middest of two muscles which bend the wrist, [tab. 22. fig. 1, ΔΘ] and proceede out of the same protuberation with it. Presently after his originall it becommeth fleshy, yet is the belly of it but small, and before it attaine vnto the middle of the cubit it passeth somewhat obliquely, afterward it is againe attenuated and groweth small or slender and determineth into a round, narrow, and long tendon [tab. 23. fig. 1. μ] which riding ouer the inner Ligament of the wrist, passeth vnder the skinne, and his tendon in the ball or palme of the Hand is dilated, attenuated and groweth to the skinne, yet so that it lyeth not vnder the part of the skin which couereth the muscles in the hillocke of the thumbe [tab. 22. fig. 3, vnder p] and those which leade the little finger from the rest. [tab. 22. fig. 1, and 3, S] Finally it is ioyned with so strong & fibrous ties to the rootes of the Fingers, that although there be a certaine fat, or substance like vnto it, (of which *Galen* maketh mention) comming betweene, yet you can scarce separate the skin of the hand from the sinewy thinnesse of this Tendon.
- Progresse.**
- Insertion.**
- Vse.** The vse of this muscle is firmly to corrugate or contract the skinne of the palme when we would hold any thing fast, for by that meanes the skinne becommeth immouable, which if it should mooue, we could not hold a thing so steddily or so safely. Haply also this Tendon is the cause why the skin of the palme hath more exact sense then the skin of the whole body: not that so quicke sense is giuen to the hand by this Tendon, but because of the foure nerues which run vnto the foure fingers.

[Table 22. is the same with Table 18, Folio 778.]

Fallopins his
observation.

Fallopins thrice or foure times found this muscle arising out of the same place in each arme double, whereof one did end into a broad Tendon, the other was inserted into the transuerse ligament of the wrist: on the contrary *Vesalius* saith that he found more then once the fleshy part thereof wanting, and then the broad Tendon was made of a portion of those Tendons that bend the wrist, [tab. 22. fig. 1, ΔΘ] before they ascend vnto the same. Sometimes also (saith *Bauhine*) the broad Tendon is produced from an internall transuerse ligament which runneth ouer the Tendons of the wrist, which also *Columbus* obserued in the dissection of some theeces.

A musculous
substance a-
rising from
the fleshy
pannicle.
The formes
of it.
The fibres.

Beside this muscle of the palme in the beginning of the inside of the hand at the lower part of the hillocke called by some *Mons Luna*, by some *Mons Martis*, by others *Veneris*, but we wil call it the Mountaine of the Moone, where the eight bone of the wrist is seated, there is found a certaine flesh. It proceedeth out of the fleshy pannicle, or from the membrane of that muscle which frameth the foresaid Mountaine of the Moone. This flesh carrieth the forme sometimes of two, seldome of three slender and short muscles. It hath transuerse fibres and runneth to the middle and inner part of the ball of the hand, and is implanted at the broad Tendon of the palme muscle, where it receiueth a complication with the fleshy pannicle which in that place is fatty. The vse of this flesh is in great contractions of the palme to draw the Mountaine of the Moone to the middle of the hand, when we would make it as hollow as we can, or else to binde in the two hillocks at the thumbe and the little finger for the same vse. Of this muscle (if so you will call it) none of the Ancients made mention, but it was first found by *Iohannes Baptista Conanus* and first described in print by *Valuerda* who yet mistaketh the vse, for he saith it was made for extension.

His vse.

CHAP. XXIX.

Of the substance which commeth betweene the skinne of the palme and
of the fingers and their Tendons.

Et wixt the Tendon and skinne of the Palme and the inner side of the fingers there appeareth a certaine fleshy substance like vnto fat, of which it shall not bee amisse a little to discourse. Although the whitish colour it hath and the hardnes do more resemble fat then flesh, yet wee conceiue that it may more fitly bee referred to a kinde of flesh, as well because it is full of sinewy fibres, as also because there are many small and threddy Veines disseminated there-through. Add also that though a man be neuer so much extenuated or consumed, yet there alwaies

remains

remaines some part of this substance, whereupon it is that *Galen* calls it flesh, and the *Arabians* thought it to be a kinde of simple flesh different from the body of a muscle. It may be objected, how then comes it to be so hard? I answer, by the contraction of the bones and of the Nervous parts which lie vpon it, and therefore it is like the fat which ioyneth vpon the ioynts of the bones. The vse of this substance is to be as it were a pillow or bed whereon the many propagations of sinews might lie soft which were derived from greater Nerves to make the hand of exquisite sense. Such a substance also is found betwixt the Tendons that bend the fingers & their skin, least when we are constrained rudely, to take holde of any hard substance the tendons should be pressed or otherwise offended, for which cause also it is very plentifull vnder the skin of the soale of the foote, yet it is to be noted that there is lesse store of it about the Ioynts least it should hinder their Motion, especially when they bend into an acute Angle.

That it is flesh
not Fat.

In like manner in the sides of the Fingers, there is some of this flesh to fill vp the spaces betwixt the Ioynts which otherwise would haue bene hollow, because the side knuckles at each bone doth stand somewhat out from the length of the bone, which equalitie was not onely made for ornament but rather and more especially to make the Hande as we say thigh, that is, able to holde a liquid substance when wee gather our fingers toward the Palme to make *Diogenes* his cup. Finally, this substance is very profitable in the toppes of the fingers for better apprehension, for if nothing had bene placed vpon the extremities of the bones which might yeelde a little when wee offer to take holde; surely the bones would haue bene in danger of breaking, and beside wee could not haue gotten holde of many things which now we do by helpe of this substance and the Naailes.

In what part
of the Finger
this substance
is.

CHAP. XXX.

Of the Muscles which bend and extend the fore fingers.

WE said before that there were two Muscles which did bend the forefingers & 16 that did extend them. The first Bender [*tab. 22. Fig. 4. F*] ariseth with a round beginning and large, mixed of a fleshy and Nervous substance, from the internall protuberation of the arme vnder the heads of the Palme-muscle [*tab. 22. Fig. 1. and 2. E*] and those two which bend the Wrist. [*tab. 22. fig. 1. Δ, ○*] Afterward becomming broader, it passeth through the middle and anterior parts of the Ell and the Wand, and becommeth fleshy and round, yet before it attaine vnto the roote of the Wrist, his Venter or Belly is angustated or straightned, [*tab. 22. fig. 1. ϑ*] and diuided into foure fleshy parts, all which doe determine into tendons exquisitely nervous and transparant: and being together involed in one common, thin and mucous membrane; for their more safe progression doe passe along vnder the annular or round Ligament [*tab. 23. fig. 1. V*] which is seated ouerthwart the wrist; & at the second bone of the forefingers nere the middest of the Ioynt are diuided with a long Section or slit through which the tendons of the next muscle to bee described (which lyeth vnder them) which were to reach vnto the third Ioynt, are transmitted. There they become broader that they might moue more easily and apprehend or take holde the better, and a little after the diuision or section they are inserted into the second bones of the foure Fingers. And truly this progresse and insertion of these muscles is an admirable and strange worke of Nature: for they are so seuered, that the fingers in their motion might orderly follow one another, and each of them alone bend inward.

The 1 Bender
of the forefin-
gers.

An admirable
worke of Na-
ture.

Moreover, as they creepe vp the first bones of the Fingers they are rowled about againe with a transuerse Ligament, which Ligament ariseth out of the inner part of the bone and maketh a kinde of Trough, wherein the tendon of this first bending muscle, together with that of the second muscle vnder it, might securely passe along the length of the Finger and holdeth it fast least it should depart from his owne seate and so decline from his owne finger againe; that when it is contracted it should not strut or arise vp, especially when wee bend the second or third ioynt of the fingers. For were it not for this transuerse Ligament which streightneth or bindeth the tendons in the place before named, they would not in their contraction be curued backward but would arise vppe like right Chords, lift vp the skin and fill the ball of the hand, whereas the Ligaments although the tendons be contracted, do yet keepe them close vpon the bones into which they are not infixed, and so the way ouer the Ligament is smooth and euen.

The trans-
uerse Liga-
ment.

The

The vse of this Muscle is primarily to bend the second ioynt, secondarily also the first, because in the passage they are firmly fastened together by the interposition of membranes and fibres, and indeed the first ioynt hath no other Muscle allotted for his flexion saving this onely.

The 2. Bender

The second *Bender* which *Laurentius* calleth *Musculum profundum*, the Deepe Muscle, lyeth behind the former [tab. 23 fig. 2, 4, G] being in the whole course, body and Tendons subiected vnder it euen to his insertion. It ariseth a little lower then the former from the pro- cesse of the Ell on the fore side thereof, [tab. 23, Fig. 2, u] and is stronger then it, because his motion is greater and of more moment. It is exactly fleshy and broad, occupying the middle part of the cubit and groweth both to the Ell from which it taketh strength, and also to the Ligament which ioyne the Ell to the Wand, and separateth the interior muscle from the exterior; but when it is descended lower then the middle of the cubit, it is angustated or groweth narrow [tab. 23, Fig. 2, x, Fig. 4, 8] and diuided into foure fleshy parts which are co- uered with a nervous coate and by degrees bring forth nervous and round tendons which perforate or make way through the Tendons of the former muscle. All these Tendons pas- sing vnder the transu. rse and membranous Ligan. ent of the wrist, are euery one of the in the ball of the hand inuested with proper membranous which are ioynd to the Tendons by ner- uous ties. Afterward they creepe vnder the foure Ligaments of the fingers, and passe through the holes or diuisions of the Tendons of the first Muscle, [tab. 23, Fig. 2, y] that so they may be implanted into the third ioynt, yet a little before their insertion they become broader, & in old men there is found a little bone like the *Sesam. n. Seede*, or like that wherewith we feede Ca- nary Birds, which hath the same vse & forme that the Patel bone or whirle bone of the knee; for as these smal bones do grow to the tendons of the first muscle, so they also grow to the ten- dons of the second muscle before they are inserted into the third bones of the fingers.

The vse of this Muscle is to bend the third ioynt of the foure fingers, yea which is more as *Arantius* hath obserued, it seemeth to contract twelue ioynts, because in his passage his tendons are affixed to the first and second ioynts by their membranous Ligaments.

And indeed if we obserue the motions of our hands well, when wee would moue the third ioynt, the two former are curued whether wee will or no, whereas the third and the second may be bent when the first is immouable and extended: & thus much of the Muscles which bend the foure fingers.

The exten-
ding muscles
of the fingers.
called *Vermi-
culares*.

The extending Muscles are 8. beside the *Interossei* of which wee shall intreat afterward: of these the first, second, third and fourth [tab. 23, fig. 2, n] are called *Lumbricales* or *Vermi- culares*, that is, the wormy Muscles, and do cleaue to the ball or palme of the hand. They are fleshy, small, round and long, and do lie vnder the tendons of the second muscle which bend the third bone of the foure fingers. They arise at the inside from those membranes of the Fin- gers which we said did euen now inuest the foure tendons: neither let it seeme hard that I say they arise from membranes, because the muscles also of the eye take their beginning from membranes. Afterward they runne along the finger on the inside, and with a nervous and small tendon they doe adhere to the tendon of the Muscle next to be described, which ex- tendeth the foure fingers. Their insertion is made about the middle of the first ioynt into the second. Wherefore when these muscles are contracted to their originals, the second and third ioynts of the fingers, together with the helpe of the Muscles called *Interossei*, are primarily extended, although the Fingers also are extended by accident, that in great constraynts they might seme to assist oblique motions. For because the Tendons of these Muscles in their passage to the exterior part of the Fingers are tyed to the laterall or side ligament of the first ioynt, they are able also with a slender motion to leade the first knuckle vnto the thumbe: and because the tendons of the next muscle to bee described are seated on the outside and therefore obnoxious to outward iniuries, Nature placed these on the inside that if by mishap the outward Tendons were violated or wounded, yet the Fingers by the helpe of these might bee extended, and this is the manner of the position of the first foure extending Muscles.

[table 23, is the same with table 19, Folio 781.]

The 5. exten-
der.

The fift Extender [tab. 24, Fig. 1, and 2, at the lower p which in the second figure hangeth downe] ariseth with an originall mixed of a fleshy and nervous substance [6] from the outward protuberation of the arme. Afterward it becommeth more fleshy, and de- scending

scending in the hinder part betwixt the Ell and the Wand, is neere the wrist about [b] much narrower, and for the most part clouen into three, rarely into foure fleshy parts, which presently degenerate into nervous Tendons exquisitely round for their better security; which Tendons are tyed together by a membranous ligament arising from the appendix of the Wand, and so are together conueighed (through a cavity exsculped or wrought in the external part of the Wand) into the wrist. And least these Tendons should at any time fall out of that cavity or when the muscle is contracted, strut vp as we see a broken veine doth, they are inuolued with an annular or round ligament. [tab. 22. fig. 2, and 4. charact. 3.] Presently after vnder the wrist they recede or depart one from another, remaining no more round, but becoming broad because the bone on the outside is round of it selfe: and one runneth vnto the second and the third ioynts of the fore-finger, another of the middle finger, and the third of the Ring-finger. And hence it is that we feele so great paine if any thing get betwixt the nayles and the flesh. Sometimes it is diuided into two Tendons onely, which are inserted into the fore and middle fingers.

The vse of this muscle is to extend the second and third ioynts of those three fingers. And the Tendons of it are long, for the bellies do not reach vnto the wrist, that the hand might be lighter and more slender for agility in his motion.

The sixth extender [tab. 24. fig. 1, and 2, 2] is slender and long, hauing a sharpe and nervous originall, which is taken from the same protuberation of the arme with the former, afterward becoming fleshy it is mingled with the former vnto the middle of his belly, so that in their originall they seeme to be but one muscle. It passeth along the Cubit through a cavity common to the Ell and the Wand, and running vnder the transuerse ligament is sometimes diuided into two nervous and round Tendons, sometimes it remaineth single. If double, one is implanted into the posterior part of the three bones of the Ring-finger, the other becoming broader is fastned into the backpart of the 3 bones of the little finger.

His vse is to extend these fingers & to leade them a little outward, especially the little finger.

The seauenth extender [Tab. 24. fig. 2, and 3, R] lyeth vnder the two former, & ariseth exactly fleshy from the middle of the Ell where you shall meete with a long and rough line made of purpose for the rise of this muscle: thence it descendeth obliquely vnto the Wand and climbing ouer the appendix of the wrist is diuided into two tendons, [tab. 24. fig. 3, op] which are transported through a proper cavity in the appendix of the Wand, and vnder the transuerse ligament. [tab. 22. fig. 2, 3. char. 4.] The vpper of these Tendons is inserted at the roote of the forefinger for the most part, more rarely at the roote of the thumbe, the lower is inserted at the roote of the middle finger, sometimes onely saith *Fallopisus* of the fore-finger: both their insertions are oblique, and indeed the whole course of muscles is oblique. Their vse is to extend those fingers into which they are inserted: beside, that in extending the fore-finger, it also leadeh it from the thumbe.

The eight extender which is also the last, (not accounting the *Interossei* in this place) [tab. 22. fig. 1, 3, and tab. 24. fig. 1, 5] is seated within the hand. It ariseth short, strong, and fleshy from the fourth bone of the wrist, and passeth by the lower part of the *After-wrist*, so ascending vnto the roote of the little finger to the outward side of the first bone, in which it is inserted slender and nervous. His vse is to extend the little finger, & withall to leade it from the rest of the fingers when we desire to comprehend any round forme as a Ball or a Globe in our hands. This muscle resembleth the fashion of a Mouse, in because the beginning & the end it is slender, but in the middest round and thicke.

And these are all the eight extending muscles. There are also eight more extenders (for we reckoned sixteene in the end of the 27. chapter) called *interossei*, of which we will intreate in the next chapter saue one, because the method & order of dissection requires that we should first speake of those muscles that bend and extend the thumbe.

CHAP. XXXI.

Of the Muscles that bend and extend the thumbe.

As we said before that there were seauen muscles which did bend the thumb, and foure that did extend it.

The first bender of the thumbe [tab. 23. fig. 2, and 4, 1] is seated in the Cubit, and beareth vpon the second bending muscle of the foure fingers, [tab. 23. 6] to which it is a little continued at the ioynts betwixt the arme & the Cubit, but they beare one vpon another in their whole progresse.

The *interossei*.

The 1 bender.

It

It ariseth with a round and fleshy originall out of that part of the Ell which is next the ioynt of the Cubit where it receiue the head of the *Radius* or wand, and so it runneth along the wand to which it groweth throughout as if the whole length of the wand did minister vnto it a continuatd originall.

Progresse,

Moreover it getteth an additament or increase by a portion it receiue from the Membranous Ligament [tab. 2.3. fig. 4.] and then running on to the wrist it determineth into a round and neruous tendon which together with the two benders of the foure Fingers creepe vnder the annular Ligament of the wrist to whose side also it is fastned. In that place it is covered with a proper mucous or slimy membrane and is hidden betweene the muscles which bend the first and second bone of the Thumbe in a cavity of a bone of the wrist which sustained the thumbe and is hollowed onely for this tendons sake. Afterward it is receiued vnder the transuerse ligament of the second bone of the thumbe and dilated into his third ioynt where it is very strongly inserted and serueth to bend it. This muscle is thicker then that which bendeth the second finger, because the thumbe is of greater strength and magnitude then the rest of the fingers. In Munkeyes (saith *Bauhine*) this muscle is not found, yet *Vesalius* describeth a Substitute for it.

Munchies,

The 2. Bender

The second Bender of the thumbe [tab. 23. fig. 1. and 2. K] ariseth fleshy from the vpper part of the annular or transuerse Ligament which is in the wrist, [tab. 23. fig. 1. V] and is fastned to all the inner region of the first bone of the thumbe, to which also it is fleshy inserted, yet obscurely; it toucheth also the second bone.

The 3. bender

The third Bender [tab. 23. fig. 24. LL] lyeth vnder the second and is farre lesse then it. It ariseth partly out of the same place with the former, partly from the bone of the wrist which lyeth vnder the thumbe and is inserted into the root of the first bone of the thumbe as farre as his middle. These two last described muscles doe bend the first ioynt of the thumbe and together with the third extender of the thumbe do make that mountaine or hillocke of flesh which is seated at the roote of the thumbe.

The vse. of 2 and 3.

The 4. bender

The fourth Bender [tab. 23. f. 4. char. 1, 2, 3. do note this muscle with those that follow next] arising with a slender and broad originall from that bone of the After-wrist which lyeth before the fore-finger, from thence it proceedeth fleshy yet somewhat narrower, and is inserted with a membranous tendon into that side of the second bone of the thumbe which is next the fore-finger.

The fift.

The fift Bender toucheth the former; is answerable to it in his originall, and being fleshy proceedeth out of the middle part of the bone of the After-wrist which lyeth vnder the middle finger. Some part of it also toucheth that bone which lyeth vnder the Ring-finger, and becomming fleshy is inserted with a small tendon into the middle of the second bone of the thumbe on the inside.

The sixth.

The sixt Bender ariseth somewhat broad from that bone of the After-wrist which sustaineth the ring-finger, and is inserted into the same place with the former: sometimes also it proceedeth with a neruous originall from the bone of the After-wrist which is vnder the little finger where it is ioynd with the wrist.

The position of the 4. 5. 6.

[Table 24. Is the same with Tab. 20. in fol. 783]
These three muscles seated vnder the line of life, haue a semicircular and distinct originall, but yet do all determine into one and the same tendon which is tyed to the inner Seede-bone which also is the greatest of all the seede-bones in the fingers, and is inserted into the side of the second bone of the same finger. And as those muscles which heereafter we shall call *inter-ossi*, seated in the after-wrist are carried directly or with a straight line, so those which bend the first bone of the thumbe run somewhat obliquely, and those that bend the second ioynt of the thumbe doe run almost transuerse or ouerthwart.

The vse.

These Muscles if they be contracted together do moue the second ioynt of the Thumbe toward the ball of the Hand. If the first of the three moue alone, the thumbe is led vpperward toward the fore-finger: if the second, it is led vnto the middle finger, if the third then is the thumbe bent downward and toward the little finger.

The seuenth.

The seauenth Bender of the Thumbe lyeth vnder these three last & is fleshy; arising from the bone of the After-wrist which sustaineth the fore-finger below the middle, euen at the iuncture thereof with the wrist. It is also ioynd (as the three last mentioned) to the second bone of the thumbe hauing a transuerse position, and occupieth the space which is betwixt the thumbe and the fore-finger. The vse of it is to draw the thumbe toward the fore-finger and to lay it thereupon. And so much of the Bending Muscles of the thumbe.

The

The *extenders* of the Thumbe are foure. The first [*tab. 24, fig. 1, the lower T*] ariseth fleshy from the outside of the cubit at his rough line neare the membranous ligament [*tab. 24, fig. 4, **] which ioyneth the cubit to the *Radius*, and passing obliquely toward the *Wand*, before it touch his appendix determineth into a round and neruous Tendon which attaineth vnto the hand through the cavity by which the by-horned muscle of the wrist doth descend vnto the ligament: and is inserted into the whole length of the Thumbe on that side which is next the fore-finger as farre as to the third ioynt. His vse is, to extend the thumbe toward the fore-finger, and to leade it from the wrist, and therefore moueth it side-long.

The second *extender* [*tab. 24, fi. 2, 3, v*] ariseth fleshy from the same line of the cubit after his length, and climbing obliquely ouer the *Wand*, is diuided into two vnequall parts, which cleaue one to another, and is seated in a proper cavity insculped or ingrauen into the appendix of the *Wand*, and is inuested with a peculiar ligament. [*tab. 22, Fig. 2, and 4, char. 6.*] The vpper part remaining a while fleshy, determineth into a Tendon almost round, and is implanted into the vtter side of that bone of the wrist which lieth vnder the thumbe. [*K*] The lower [*L*] is subdiuided into two fleshy portions, both which doe end into a Tendon: one of them groweth very strongly to the roote of the first ioynt of the Thumbe: [*m*] the other with the membranous tie cleaueth close to his second and third bones. [*n*] His vse is to extend the Thumbe inward.

The third *extender* [*tab. 22, Fig. 4, P. Tab. 23, Fig. 1, x.*] ariseth with a neruous originall, (which presently after becomes fleshy) from the inner part of the bone of the wrist which sustaineth the Thumbe. After being carried downeward, it is inserted with a membranous Tendon into the first ioynt of the Thumbe which it leadeth from the foure-fingers. This muscle with the second and third benders of the Thumbe make that fleshy portion of the palme which is at the roote of the Thumbe, we commonly call it the brawne of the hand.

The fourth *extender* [*tab. 24, Fig. 1, 2, 3, 4, z.*] occupieth the space which is betwixt the Thumbe and the fore-finger. It ariseth fleshy (partly also finewy) from the inner and backer part of the bone of the After-wrist which lies vnder the fore-finger, and is fleshy inserted on the whole outside into the first ioynt of the thumbe. Moreouer it trasmitteth a membranous Tendon to the second, which *Fallopins* in his *Institutions* acknowledgeth he hath found, but in his obseruations he saith he could neuer meete with it. This muscle serueth for the laterall motions of the Thumbe. It leadeth it also to, and layeth it vpon the fore-finger. And so much for the muscles of the Thumbe as well benders as extenders. Now we proceede to the muscles of the After-wrist and wrist.

CHAP. XXXII.

Of the Muscles of the After-wrist and the wrist.

THE After-wrist called *Metacarpus* or *Postbrachiale*, is a part of the hand seated betwene the wrist & the fingers. It hath eight Muscles, for in euery distance betwixt bone and bone, there are two Muscles which are fastened to the sides of the bones and therefore are called *Interossei*. Those that arise from the bones to which they grow, are throughout fleshy and run directly according to the length of the bones, creeping on the back-sides of their fingers, and their Tendons are mixed with the Tendons of the foure first extending muscles of the fingers which we called the Worme-muscles. Sometime this mixture is made before their Insertion, so that the wormy and bone-bound Muscles do seeme to make but one broad Tendon.

They are a little gathered or bound together by a Ligament of the first ioynt, and run by the sides to the outward Tendons of the fist muscle that distendeth the fingers, into which also they are inserted and with them are the authors of the extension of the second and third ioynts of all the Fingers; and because they cleaue to the sides of the fingers, it should seeme they were ordained to part the fingers asunder, and to leade them againe together.

Hence it is, that if a man be wounded on the outside of the After-wrist, he loseth the motion of the first ioynts of the fingers, because the muscle which extendeth the finger is cut asunder, yet the second and third ioynts are strongly and quickly extended because these small muscles do remaine sound. These muscles do make the inward cauitie in the After-wrist so plaine and equall (like as others do the same in the foote) that the particular Tendons

of these muscles may run directly to the performance of their offices vpon a smooth and soft bed. They are also by this meanes secured from the offence which they could not otherwise but receiue by the hardnesse of the bones vnder them. Finally, they do not suffer those muscles together with the fat placed aboue them, to bee exiccated or dried but maintaine and cherish their moysture.

The muscles
of the wrist.

The next part of the Hand is the wrist called *Carpus* or *Brachiale*, and is in the midst betwixt the Cubit and the After-wrist. The motions of the wrist are to be bent, to be extended & to be inclined to either side, wherewith also the rest of the hand is mooued with one and the same motion, and all this is performed by the helpe of foure Muscles, whereof two seated within do bend, and two extend which are seated without.

The first bender.

The first bender which is also the lower, [tab. 22. f. 1, 3, 4. and tab. 23. f. 1, and tab. 24. f. 1, and 2, Δ] ariseth with an acute originall (mixed of a fleshy & neruous substance) from the inner or lower protuberation of the arme, and being fleshy strengthneth himselfe by adhering vnto the length of the Ell euen vnto the wrist, and for retribution serueth the bone for a pillow, which vse we especially make of it when we write, for then we leane vpon this muscle. Presently after, that is to say at the very wrist, it degenerateth into a fleshy and neruous Tendon which is implanted into the fourth bone of the wrist called by *Galen* *Os Cartilaginofum*, & to the Ligaments of that Ioynt it is connected & compassed about with a common Membrane, [is his beginning and his insertion.]

The second bender.

The second Bender or the vpper [tab. 22. f. 1, and 2. and tab. 23. f. and 6] ariseth from the same protuberation and descendeth obliquely after the length of the Wand, but before it come to the roote of the Wrist it endeth into a strong Tendon, which hauing ouer-past, the inside of the wrist becommeth broader, and is inserted into the roote of the bone of the After-wrist which sustaineth the fore-finger. It groweth also vnto the transuerse Ligament.

The vse of the
two Benders.

These two Muscles if they worke together do bend the Wrist forward, and secondarily the hand also: but when one of them onely worketh it mooueth obliquely now vppward now downward that part of the Wrist into which it is infixed, yet it giueth some ayde to the two Muscles which are seated without.

The first Extender.

The first Extender or the lower [tab. 22. f. 4. and 24. f. 1 and 2, Δ] seated betwixt the first muscle of the Wrist and the first extender of the Fingers, taketh his originall aswell from the roote of the externall or vpper protuberation of the arme, as also from the top of the cubite which it embraceth; it runneth through his length, and when it attaineth to the Wrist, it is infixed with a round, neruous and strong Tendon aboue the appendix of the Cubit into the bone of the After-wrist which lyeth vnder the little Finger, and not farre from the Wrist. Sometimes also before his Insertion, it hath a Seede-bone growing to it.

The second Extender.

The second Extender or the vpper which is also called *Bicornis* or the two-horned Muscle [tab. 22. f. 2, 4. c and tab. 21. f. 2, 3. E] ariseth fleshy with a broad beginning from the bony edge which is in the arme aboue the exterior protuberation [tab. 24. f. 3, X] It runneth vpon the Wand and aboue the middest of it determineth into a thicke, strong, and double horned Tendon, whence it hath his name saith *Columbus* and *Archangelus*, and when it hath directly ridden ouer the Wrist, the one of them is inserted into the first bone of the After-wrist, which sustaineth the fore-finger and into the extremity or end of the Wand: the other is infixed into the second bone of the After-wrist, vppon which the middle Finger leaneth. *Archangelus* saith that hee hath often found this two-horned muscle double, that is to say, two Muscles; one greater whose originall was neruous, and whose Tendon ended below the ioynt of the arme into foure Fingers. The other lesse, whose originall was neruous also, but his Tendon ended in the middest of the Wand. Hee addeth also that his Tendons are first broad, afterward round.

The vse of the
2. extenders.

These two extending Muscles if they worke together, doe bend the wrist outward and extend it primarily, secondarily also the hand; and are holpen by a portion of the thirde muscles which extendeth the Thumbe. Secondarily also they leade the Wrist about when one in his motion immediately followeth another. But when one of them onely worketh, then diuers motions are produced: for if cyther they worke asunder, or one of the benders worke together with an extender, it mooueth the Wrist obliquely and to the side. And thus much of the Muscles of the After-Wrist and the Wrist, now wee proceed vnto the Muscles of the Chest.

CHAP. XXXIII.

Of the Muscles of Respiration.

THe Chest contrayneth the Instruments or Organs of life : Life cannot be maintayned without Respiration, neither can Respiration be performed without motion ; it followeth therefore that the Chest must needs be moued for Respiration sake. If it be demanded why Respiration is so necessary, we answer, because of the high and great heate of the Heart, which by the ayre attracted in Respiration is refrigerated and cooled, euen as a mans face in Summer is cooled by a fan that wafteth fresh ayre vnto it.

Now the Chest is moued either by it selfe or by accident when it followeth the motion of the Spine or Rackbones of the backe, for when the backe is bent the Chest is also bent with it.

It is moued by it selfe and with a proper and peculiar motion for Respiration sake, which Respiration is accomplished by a double motion of the Chest, which is dilated when Inspiration is made, that is, when we draw the ayre into our Longues and so coole the heate of our Hearts; or contracted in Expiration, that is, when the ayre is driuen backe through the Rough artery for the generation of the voyce, and the footy excrements are blowne away least the Heart should be suffocated by them.

In these motions of the Chest wee must consider notwithstanding, that in Inspiration the lower parts of the Chest are dilated and the vpper angustated or straytned : on the contrary in Expiration the lower are constringed or straytned, the vpper dilated. And this was the reason why the Chest was not made of one bone as was the Scull, but of many, which also are ioyned together by gristles that their motion might be more pliant and easie.

But as the heart is moued with Naturall motion, so the Chest is moued partly with Naturally partly with Voluntary motion : with Naturall, because in our sleepe it is moued Naturally not according to our Will. With Voluntary, for wee haue read of some that by retaining their breath haue hastned death vpon themselves. As for the Longues they follow the motion of the Chest especially to auoyde vacuity, as well in those that sleepe as in those that are awake.

Philosophers doe differ much concerning these motions, but because wee haue already touched vpon their disputation in the tenth question of the sixt Booke, wee will not here Tautologize though haply we might say something new, because this Volume groweth far beyond that extent which was first limited for it.

The Chest therefore needed Muscles for Respiration, Respiration is absolued by his Diastole or dilatation when we breath in, and by his Systole or contraction when we breath out. These Muscles are in all 65. on each side 32. that is to say, 22. *Intercostall* Muscles, 11. internal and as many external, and one which is common to both sides called *septum transversum* or the Midriffe. Of these wee haue spoken before in the fourth and fift Chapters of the sixt Booke.

There remaine yet the proper Muscles of the Chest, fixe on either side, vnlesse it please you to adde three more according to *Fallopins* : Finally, the Muscles of the *Abdomen* (which helpe also our Respiration) are on each side foure beside the *Pyramidals* or Spirie Muscles, so that the whole summe will now amount to 71.

Of these some are Common, as the Muscles of the *Abdomen* which beside Respiration doe serue also for other purposes, others are Proper and serue for Respiration alone. But Respiration is double, one Free or naturall, the other constrained or violent.

That wee call Free which is done gently and easily, that is, when in Inspiration there is without constraint so much ayre drawne in as may suffice for the generation of vitall spirits, and in Expiration when a part of the attracted ayre is againe gently returned for the generation of the voyce, and both these are wrought by the motion of the Midriffe alone.

The first by the Contraction of the Midriffe wherein the end of the bastard ribs are gathered a little vpward, the lower and forward part of the Chest angustated or straitned and the backepart enlarged to the Racke bones, the seauen lower ribbes parted as it were asunder and so the Chest dilated. The second, when the Midriffe is relaxed or loosened, for then the Chest doeth easily fall with his owne waight.

We call that Respiration constrained, when the Dilatation or Contraction of the Chest is constrained,

eident, that is, when in Inspiration the breath is drawne with violence or vehemencie, as it happeneth when the heart is too much heated: and in Expiration when the ayre is forcibly blowne out, as when we would speake or hallow aloud, when wee would cough or sneese, or else when vpon expulsion it is retained when we would make vse of the midriffe in euacuation of excrements or such like.

How the muscles moue.

This respiration is absolved by sixtie foure Muscles assisted by the midriffe, yet so that in Inspiration fewer Muscles do labour then in Expiration. In Inspiration, that which is called *Subclavius*, *Serratus maior*, *Serratus posticus superior & inferior*, and *Fallopian* his 3. Muscles. The Intercoftall muscles doe also conferre to this businesse, but that by accident onely. In Expiration more muscles are required, because we breathe out with greater strength then we breathe in; these are called *Sacro-lumbus*, *triangularis*, and all the Intercoftalls; for the exterior doe leade the lower ribs vpward, and the interior the vpward ribs downward. The eight Muscles of the *Abdomen*, and haply in great necessities the Muscles of the arme and the shoulder blades doe lend their helping hands. The Intercoftall muscles wee will here altogether passe over, as also the midriffe, because we haue spoken of them at large before. The muscles of the *Abdomen* we referre vnto the next chapter, here we will onely handle the proper muscles of the Chest, which grow thereto. These are accounted by *Galen* eight, and so many they are indeed in Apes, but in men there are but sixe in either side commonly receiued, to which *Falopius* addes three.

Their position of the muscles.

Two of these muscles are seated before, the one called *Subclavius*, the other *Triangularis*, one occupieth the sides called *Serratus Maior*, the rest lie vpon the back part, three in the backe, two called *Serrati postici*, and the third *Sacro-lumbus*; three in the necke, and these are

Tab. 25. Sheweth the Muscles especially of the chest, the head and of the shoulder-blade.

TABVLA XXV.

- A, The fourth muscle of the Chest, or the vpper and hinder Saw-muscle.
 B, the 5 muscle of the chest or the lower and hinder Saw-muscle.
 a, b, A membranous beginning of the muscle of the *Abdomen*, descending obliquely downe from the Spine of the backe.
 C, the 1 muscle extending the Cubit at c his originall is from the necke of the arme, and from the lower basis of the blade at d.
 E, the originall of the fourth muscle of the bone *hys* from the blade.
 G, G, the outward intercoftall muscles.
 I, the Clauicle or Collerbone bared.
 N, the vpper, the 2 muscle of the arme cald *Deltoid*, Char. 4, 5, the beginning of this muscle.
 N, the third muscle of the arme or the broad muscle separated.
 O, the fourth muscle of the arme or the lower *Super-Scapularis* or bladerider.
 I, 2, 3, Char. His originall at the basis of the shoulderblade at 1, 2, and his insertion into the ioynt of the arme at 3.
 Q, the sixt muscle of the arme or the vpper *Super-Scapularis*.
 X, The fourth muscle of the blade called *Leuator* or the heauer.
 Z, the second muscle of the Chest or the greater Saw-muscle.
 7, 7, Char. The ribs.
 T, the sixt muscle of the chest, or the muscle called *Sacro-lumbus*.
 A, The first muscle of the head or the splinter.
 EE, the second muscle of the head or the insertion of the muscles called *complexi*.

 n, The fourth muscle of the backe called *Semispinatus*.

they

they which we said before were propounded by *Fallopianus*. But by *Vesalius* are esteemed to be parts of those muscles which occupy the necke and the backe, but wee come to the particulars.

The first proper muscle of the Chest is called *Subclavius*. [*tab. 17, r. tab. 22, fig. 3, r.*] the reason of the name is, because it is seated vnder the collar-bone which is called *Clavicula*, for it filleth that space which is betwixt the clauicle and the first rib.

1. subclavius.

This muscle ariseth fleshy from the inner and lower part of the clauicle which is next to the rib, runneth obliquely forward and is fleshy implanted into the vpper part of the first rib which is ioyned to the breast bone. His fibres are oblique, yea almost transverse. The vse of it is to draw the first rib vpperward and outward, and so the cavity of the chest is dilated.

The second muscle is called *Serratus Maior* or the greater Saw-muscle. [*tab. 10, 17, 25, 22*] It is a large muscle, situated in the side of the Chest, broad also and every way fleshy. His originall is large and fleshy from all the inner basis of the blade, and towards the ribs it is dilated, coucheth vpon them, is tyed to them by fibres, and is inserted as it were diuided into fingers into the eight vpper, sometimes also into the ninth rib, before they doe determine into their gristles. And these insertions of those muscles are acute or sharpe because of the tendons which descend obliquely with points like the teeth of a Saw, to meete with the teeth of the oblique descendent muscle of the *Abdomen*, with which they are finger-fanged as also is the lower and backward Saw.

2. Serratus maior.

The vse of this muscle is by the collection of his fibres in great and violent constraints or endeuours to draw the eight ribbes outward, and so to dilate the Chest. But in dogges and Apes it is not only inserted into the eight ribs, but implanted also into the transverse processes of the fourth, fifth, sixth and seauenth rackbones of the necke, or if you please it ariseth therefrom.

The third proper muscle of the Chest is called *Serratus posticus superior* [*table 25, 4*] the vpper backe-saw. It lyeth in the backe vnder the muscle called *Rhomboides* or the thirde muscle of the blade, betwixt both the blades and aboue the first muscle of the head. A little muscle it is, and ariseth broad and membranous from the spines of the three lower rack-bones of the necke and the first of the Chest. Afterward it passeth a little obliquely vnder the blade, becommeth fleshy, and being diuided into three parts is inserted into the three distances of the foure vpper ribs.

3. Serratus posticus sup.

The vse of it is to draw the ribs vpperward, to which it is implanted by contracting his fibres, and so the Chest is dilated and the hinder cavity thereof enlarged.

The fourth is called *Serratus posticus inferior*, the lower backe-saw [*tab. 25, B*] and seated almost in the middle of the backe vnder the broad muscle that is the third muscle of the arme. It ariseth membranous, nervous, broad and almost quadrangular like a combe as the other (but broader then it) from the Spines of the two lower rack-bones of the Chest, sometimes of the three, sometimes also from the vpper rackes of the loynes. Afterward it passeth ouerthwart and lyeth vpon the muscles of the backe, and being increased with fleshy fibres is inserted at the distances of the foure lower ribs before they determine into gristles. The insertion is made into the ribs themselves, and the muscle at the insertion is diuided as it were into fingers. It is much broader in men then in apes and dogs, and in dogs larger then in apes.

4. Serratus posticus infer.

The vse of this muscle is to draw the three or foure lower ribs outward, and so doth dilate the lower part of the Chest as we saide the second muscle did dilate the vpper part.

The fift muscle is called *Sacrolumbus* [*tab. 10, r.*] sayeth *Laurentius* and ariseth from the *Os sacrum* and the Spines of the *Lumbi* or loynes. This muscle may be thought to be common as well to the Chest as to the backe. It lyeth vnder the former, and ariseth fleshy from the backe part of the *holy-bone*, and the vpper and inner part of the haunch bone. Afterward it creepeth vpperward fastening it selfe to the transverse processes of the rackes of the loynes, and as farre as to the lower racke of the chest is mixed with the longe muscle of the backe, [*tab. 10, at 9*] so that a skilfull hand can very hardly separate them, and therefore it is esteemed but a portion thereof. [*tab. 10, 2, 3*] A little aboue the racke-bone of the Chest it departeth from the other muscles to which it doth grow, and becomming by degrees more slender, is inserted obliquely with round tendons not altogether fleshy produced from the outward side [*tab. 10, 37*] into fixe protuberations of the lower ribs which are their rootes. From thence (as *Fallopianus* rightly obserued) are produced fixe new fleshy muscles, nervous both in their originall and insertion, and are implanted into the fixe vpper ribs: so that from the twelfth rib

5. Sacrolumbus.

6. Fallopianus his 6. new muscles

where this muscle is inserted there ariseth a certaine Tendon, which becomming fleshy and climbing vpward looseth his flesh againe and is infixed into the sixth rib, carrying the resemblance of a slender muscle. In like manner from the eleventh rib proceedeth another Tendon which is inserted into the fifth rib, and one also from the tenth which is inserted into the fourth, one from the ninth into the third; finally, from the eighth and the seauenth which are implanted into the first ribs.

All these Tendons doe resemble distinct Muscles, yet they are so commixed together and with the *Sacrolumbus* in the surface that they seeme to bee partes thereof whereas indeed they are not, so sayth *Fallopins* in his obseruations. Wherefore when as the *Sacrolumbus* draweth the fixe inferior ribs backward and therewith downward, it moueth also together with them the fixe vpper foresayd additaments which are called *ansule* or the handles, and so constringeth the Chest.

The 6. proper muscle.

His originall

The sixth proper muscle of the Chest hath his name from the forme and is called *Triangularis* or the triangular muscle, because it consisteth of two long sides and one short. It is seated within the cavity of the Chest vnder the breast bone: little it is and slender, and in some men (especially if they be leane) there appeareth nothing fleshy in it. In some parts it is like a neruous Membrane stuffed with flesh. It ariseth from the lower part of the Breast-bone and passeth obliquely vpward and outward, growing to the gristles of the true ribs euen vnto the second: and this is the reason why the *Intercostall* Muscles and those which are called *Intercartilaginei*, that is, betwixt the gristles, doe appeare diuers, because of their diuers fibres. The vse of this muscle is to leade the gristles of the ribs together, and so to constringe the chest or to pressedowne the forepart thereof so much as is necessary for the Respiration, but in Dogs it is wholly fleshy and occupyeth the whole side of the Breast-bone.

Fallopins his 3. muscles.

Fallopins is of opinion that the first and the third Muscle are too weake to suffice for the eleuation of the Chest, for hee esteemeth the second rather to be a moouer of the blade; and therefore he saith that there are three other muscles which performe this office placed in the necke, which *Vesalius* in his Apology accounteth for partes of these Muscles which occupy the necke and the backe.

The first of these three ariseth with a neruous beginning from the inside of the transuerse processes of the 3. 4. 5. and sixe Racke-bones of the necke; then becomming more fleshy it is infixed into the first ribbe which it lifteth vp, and together with it the whole Chest.

The second is called *Scalenus*, because his figure is vnequally triangular, [Table 29. a. tab. 13. CC.] It ariseth fleshy from the transuerse processes of all the racke-bones of the necke, the first and second being sometimes excepted, and hath a fleshy insertion into the first rib, sometimes also into the second. This also serues to lift vp the Chest.

The third and last ariseth from the transuerse processes of the fourth and fifth rackes of the necke, and is implanted with a fleshy termination into the second ribbe sometimes into the third, and lifteth vp the rib into which it is implanted.

By these three muscles therefore and the *upper back saw*, *Fallopins* conceiueth that the chest is eleuated. And thus much shall suffice to haue sayde concerning the muscles of the Chest. Now follow the Muscles of the Abdomen.

CHAP. XXXIII.

Of the Muscles of the Abdomen or Paunch.

The order of the muscles of the Abdomen.

Here be tenne Muscles which couer the heather Belly, on either side siue called the Muscles of the Abdomen which are placed in this order. First doe appeare two obliquely or sidelong Descending & as many Ascending, which haply may more rightly be distinguished if they be called the oblique externall and oblique internall, for they all ascend equally as a mans eye please. Next two Pyramidall, after them two Right Muscles, and last of all two Transuerse or overthwart, so called according to the leading of the fibres which do mutually deuide themselves, as rightly so obliquely and sidelong.

The oblique or sidelong descending, or oblique externall Muscles [tab. 26. AB] so called of their oblique fibres [tab. 26. H] are placed in the sides: they are of a Triangle Figure, and amongst all the Muscles of the Abdomen the greatest and the broadest. These where they are more fleshy proceede from the top of the haunch-bone, [tab. 26. f] and from thence haue their

their strength and firmnesse; more neruous they proceede from the share-bone [tab. 26.g] where they are perforated, and membranous from the membrane springing out of the Ligaments of the spondels or racke-bones of the loynes: and so rise vpward and ending somewhat fleshy do cleaue to seauen, sometimes to eight of the lower ribs before they determine or end into their gristles.

Their situation.

That they doe arise from below it is manifest, because by all mens consent they serue to dilate the Breast and so helpe Inspiration; and therefore they must end in the Breast and not arise thence-from, because it is a ruled Axiom that euery Muscle draweth toward his owne originall not toward his insertion. They are therefore inserted into the great Saw-muscle [Tab. 26. ee tab. 27. p tab. 28. 000] at the 6. 7. 8. and 9. ribs as it were with [tab. 26. bb] a Finger-fould, as also into the lower backe Saw at the three lowest ribbs: sometimes they are ioyned to the Pectorall Muscle with a thinne neruous Tendon. Forward they [table 26. cc] are carried with a broad neruous and membranous Tendon, and in the middle of the Abdomen doe so mingle themselves at the white Line [tab. 26. ddd] that they make as it were a coare which spreadeth ouer all the Abdomen. These muscles are ioyned also to those vnder them by the interposition of a slimy substance like fast glew.

This white Line [tab. 26. ddd. tab. 27. ee. tab. 28. EE] is in the middle of the Abdomen, bred out of the concurrence or meeting of all the Tendons of these Muscles except the right. For the Tendons of the oblique muscles are so closely vnited, that it seemeth but one Tendon, and the Tendons of the inferior oblique do so grow to the Tendons of the transuerse where the right Muscles doe separate themselves, and so meete in one line, into which also the Pyramidall or spiry Muscles are implanted.

The white line.

This Line beginning at the Sword-like Cartilage or the Breast-blade neruous, passeth vnto the commissure or ioyning together of the share-bones: above the Nauell it spreadeth itselfe broader but below it is narrower: and is therefore white because there is no flesh or red soyle vnder it. It serueth to hold together all the Muscles as in a common end or termination, that so the right Muscles might remaine in the right side and the left in the left, and neither be halled ouer his limits. It hath also sometimes Fatte lying vpon it.

The vse.

The oblique ascendent [table 26. D table 27. i reflected from the abdomen] or oblique internal Muscles which doe intersect the former with their oblique ascendent fibres like S. Andrewes Crosse, or in the manner of the Greeke Letter χ [tab. 26. I H] doe occupy the middle part of the Abdomen, and are of a Triangular Figure. They arise fleshy from the appendize of the haunch-bone, and membranous from the membrane before named, and the Spines of the Holy-bone, and being increased with fleshy fibres and couering the haunches doe ascend vpward, and becomming fleshy are knit vnto the gristles of the foure lower ribs, and so are brought to the forepart of the Abdomen, and end in a broad neruous and membranous Tendon: which when it meeteth with the right [tab. 27. b] Muscles is diuided into two Tendons, one of which passeth above the right Muscle, the other creepeth vnder it (for which cause Galen writeth that the right Muscles are not couered with any externall Muscle, meaning there by Muscle Flesh, for that that couers them is indeede but a Tendon:) so that by this imbracement the length of the right muscles is fortified and kept safe from solution or breaking, and as it were hemmed in the midst of three muscles; where they doe not as before couer the muscle after the manner of a membrane, but doe so adhere to the intersections and partitions of the right muscles, that their tendons can bee very hardly seuered from them.

The oblique internal.

Their original

Their tendons.

Being passed the right Muscles, they againe mingle themselves, are firmly and closely knit and vnited, and so goe hence away to the white Line [table 27. ee] framing as it were another membrane, and above doe meete with the Sword-like Cartilage or Gristle of the Chest. Below they meete a little vnder the Nauell, but the vpper Tendon is inserted into the share-bones.

These foure Muscles haue Veines and Arteries from the Muscle-veine and Artery, springing about the Loynes which are disseminated through all the region of the Abdomen and the Peritoneum or Rimme of the Belly: they receiue nerues also from the last spondels or racke bones of the Chest, which are inserted according as the leadings of the fibres are.

Their vessels.

The proper vse of the externall oblique Muscles, is when they worke together obliquely, to compress the vpper and side parts of the lower belly on either side, and of the oblique Internal in like manner to compress the lower and side parts: but wee must not conceiue

conceiue

Tab. 26. Sheweth all the Muscles of the lower belly, on the left side the oblique muscles, & on the right side the Pyramidall, the right and the transverse.

TABVLA. XXVI.

ceive that all the lower belly is by these Muscles compressed, because their Tendons reach but a little below the Nauill. The compression is therefore made on either side but to the top of the groyne, for they are inserted into the gristly and moouable partes of the Ribbs.

The Pyramidal muscles.

They are often wanting.

The use of the spiry muscles.

The Pyramidall Muscles, so called from their forme like a Pyramis or Broch, arising from the outside of the sharebone [tab. 26. F, tab. 27. g] with a fleshy and nervous beginning (siding together like two parts of a spire, (for they are seldome so vnited that they make but one Muscle) doe clime with oblique fibres over the heads of the right Muscles from whom they are distinguished by a peculiar membrane and different fibres; and doe end in the white line (neuer in the right Muscles) with an acute Tendon of their owne, but one longer then another, neyther in length exceeding the breadth of foure fingers; but these though they be most commonly seene in dissections, yet in many bodies they are wanting, although Fallopius neuer dissected body but he found them.

The use of these spiry Muscles is to compress the bladder, for if one of them worke alone, it draweth the white line obliquely downward. If they worke together, they draw it directly downward, and so compress a part of the groine and the bladder there-vnder, when we make water at leisure. For if wee force our water with any violence, then the other Muscles of the Abdomen doe also helpe, pressing the whole paunch and with it the bladder. And if we marke our selues in such straining, we shall manifestly perceiue that the Abdomen is contracted downward; and hence it is that they are also called *Succenturiati* assistant Muscles because they helpe all the rest.

And if at any time (as it happeneth but seldome) these pyramidall Muscles bee wanting, then the oblique ascendents doe not take their first originall from the appendix of the

the haunch-bone, but lower from a strong ligament which runneth from the aforesaid appendix vnto the share-bone, & then they vrge obliquely downward whatsoeuer is vnder the groyne as is the bladder of the vrine. They also adde strength to the heads of the right muscles, to which also they serue as a defence. Whereupon some haue imagined the (though falsely) to be another originall of the right muscles. For if wee gently auoide our vrine neyther the inspiration nor expiration is interrupted, which yet certainly would be if they were parts of the right muscles, because when the right muscles are contracted, the Chest also is compressed, whence it would follow that when by the contraction of these muscles we would exclude our vrine, we cannot draw in breath till wee remit or loosen the intention of the Muscles.

The Right muscles [tab. 26, EE. tab. 27. AA, they are marked with d d] haue their name both from their right fibres, and because they are placed according to the straight length of the body: they are situated vnder the neruous thinnesse of the oblique, and in some places ioyned vnto them: they occupy the higher place, whereupon their tumors being longer then round, may easily be distinguished from the tumors of other parts by their position. Their originall is neruous from the fore & vpper [tab. 27, bb, tab. 28, charact. 1, 2.] part of the share-bone, (not from the brest because the bones of the share, hips and haunches are not moued) but presently they become more fleshy, and climbing ouer the belly about the nauill do seeme as it were to bee vnited [tab. 27, f] which yet is but the vicinity of their originall: but by how much they ascend higher by so much are they more seuered [tab. 27, ee] and grow broader, and doe at length grow to the Cartilages or gristles of the lowest true ribs at the sides of the brest-bone with a fleshy and ample insertion. [tab. 27, cc] They are fleshy and strong the better to compress the fore side of the Abdomen, and haue three, seldome foure intersections or partitions very neruous and transuerse or ouerthwart [tab. 26, charact. 1, 2, 3, tab. 27, ddd] as it were hanked together, so that they seeme to be not one, but many paire of right muscles, diuided and distinguished by the trending or oblique bending of their fibres to these surled intersections.

These intersections are firme and solid membranes, whereof one is vnder the Nauill, two and sometimes three aboue it; all which are ordained cyther to strengthen the muscle which is appointed for especiall hard imployment, particularly in deepe expirations; or

else

else that being obliquated or *shelued* after the round figure of the *Abdomen* and fastened with the Tendons of the oblique ascendants they might more closely presse the *Peritoneum*. They haue veines which we call *Recurrents*, and arteries from the *Epigastricke* [tab. 28, 11. fig. 2, b] (from which also branches are sent to the necke of the womb) diuided into many furcles or tendrils for their nourishment and life. Which being led vpwrd vnder their bodyes are about the nauell, [tab. 28, fig. 2, c c] ioyned with the internall mammary or paps [tab. 28, fig. KK. fig. 4] veynes (which descend vnder the brest-bone) by *Anastomosis*, that is, inoculation of their extremities.

Anastomosis
what it is.

Which *Anastomosis* or kinde of vnion is the reason of the great consent betweene the wombe and the paps, the *Abdomen* and the nostrils. This consent of the wombe with the paps, is also increased by certaine internall veines, one called the *Axillarie* which goeth vnto the paps, and by the branches of the *Hypogastricall*, which are distributed vnto the wombe.

[Tab. 28. is the same with tab. 5. in the 2 Booke, fol. 78.]

They haue sometimes foure nerues most what proceeding out of the middle of the last spondels or rackbones of the Chest and so reaching to their hanked or surled interfections or distinctions. Their proper vse is to driue the highest and middle part of the lower belly not downward but directly to the Spine, to compresse it and to presse downe the lower parts of the Chest by drawing them directly downe ward. They helpe vs also in violent Expirations.

The vse of the
right muscle.

The transuerse
muscles.

The transuerse or ouerthwart Muscle, [Tab. 26, GG. tab. 27. III. and tab. 28. M. a part of it is reflected,] is placed ouerthwart the belly, and so named from the transuerse [tab. 26. KK] fibres which run through the breadth of their bodyes. These are vndermost and doe arise neruous from the inward endes of the bastard ribs, and the membrane twice before spoken of, and are inserted, being become more fleshy to the haunch-bones, [tab. 28. N. where the haunch-bones are bared, at which the transuerse and oblique Muscles doe meete and are implanted,] which after they haue inuested and attained to the vtmost sides of the neruous and membranous Tendon like that of the oblique Muscle, and tend vpwrd to the swordlike cartilage or brest blade, forward to the white line and downward to the groyne, and doe so closely adhere or cleaue to the *Peritoneum*, that in a man they can scarce bee cleanly separated from it, but in the groyne this *Aponeurosis* or broad Tendon forsaketh the *peritoneum* or rime, and leaueth it bare.

Ruptures.

Their vessels they receiue like the oblique Muscles. Their proper vse is to compres ouerthwart the middle and laterall parts of the lower belly, and especially the collicke gut. The tendons of these as also of the oblique Muscles are perforated at the exiture of the nauell to giue way to the vmbilicall or nauell vessels, and againe, on both sides neare the share bone, that the preparing vessels of seede may descend through them to the testicles, and the ciaculatory may ascend to the prostates which are annexed to the necke of the bladder. Through these perforations [tab. 28. *] the inward coate of the *peritoneum* being broken, or by stretching being dilated, the guts or the Kell slipping downe, cause the *Hernia* or Rupture. Beside those perforations common to both sexes, they are also bored in women for the passage of those sinewy processes which are called *Cremasteres*, which doe reach vnto the viter part of the lappe, whereupon women are troubled with the *Bubonocoele*, and of it are cured by section.

The reason of
their situation
from their vse.

That the transuerse haue an inward situation, the right a middle, and the oblique an external; a reason may bee giuen from Chirurgicall deligations or ligatures, because ouerthwart bandes doe presse or constrain more then right, and right more then oblique or side bands.

The vse of the
muscles of the
Abdomen in
generall.

All these muscles of the *Abdomen* (whose substance is partly membranous partly fleshy that they might be stronger for motion) haue this common vse with other Muscles, that whilest they are at rest they serue for a muniment or defence vnto the parts subiected vnder them, beside they contayne or hold the inward parts within their precinct, and keepe the body warme.

Particularly when they are together contracted toward their originals, and curued inward (the soft entrals giuing way vnto them) and are helped by the Midriffe depressed vpon the retention of the breath, then doe they equally and all ouer compresse the lower belly, (for if they worke seuerally, they presse sometimes one part, sometimes another) by which compression the excrements are thrust downe into the great guts and there re-
rayned

retayned at the fundament by the sphincter Muscle are thrust out by a reclusion or opening of the passage and a relaxation of that sphincter, and thereupon they bee called the instruments of the Excretion by *Galen* in the 15 chapter of his fifth booke *de usu partium*. But because the compression is equall from euery part, these excrements should as well be pressed vp to the stomack, as downe to the fundament, sauing that the midriffe by his oblique situation and the breath retayned, doth drine them downward and helpe Excretion. They assist the Mother also in the time of the birth, by constringing or binding the *Hypochondria* and by drawing downe the ribs. They helpe also the motions of the Chest, for saith *Galen* in the 14 chapter of the first booke *de usu partium*, they forme the voice, serue to inspiration and Expiration and in strong Effusions, as when a man windeth a Horne: yea sayeth *Galen* they helpe vs also to hold our breath.

Wherefore these Muscles doe night and day assist the breast in Respiration and the lower belly but at some times when we would vnburthen it, therefore they may be thought to bee principally ordayned for the motion of the Chest. Againe, because the Chest hath many other Muscles which doe distend and contract it, but the lower belly these alone, it may therefore be imagined that their primary vse is to bee referred to the lower belly, their secondary to the Chest.

Finally, if each Muscle worke by it selfe, then the oblique descendend drawes the haunch obliquely to his owne side, the right to the right side, the left to the left: the oblique ascendend leadeth the chest obliquely to the haunches; the transverse drawes the paunch, the right into the right side, the left into the left.

It is also worthy obseruation that the figure of these Muscles whether they labour or rest at quiet, is other and different from the figure of the other Muscles: for these of the *abdomen* before they worke are crooked, and in their contraction hauing soft bodies vnder them they are bended or crooked inward: all other Muscles whilest they are at rest are right, when they labour they are curued and bend outward, because of the bones against which otherwise they should offend. And thus much of the Muscles of the *Abdomen*: now we proccede vnto the backe.

The worke of each Muscle alone.

Their figure why differing from other muscles.

CHAP. XXXV.

Of the Muscles of the Backe.

He Muscles of the Backe as also of the whole Spine are so diuers, so mixed and knit together that some Anatomists haue diuided them into more, others into fewer Muscles, being led thereunto by reason of the infinite originals of the fibres and the multitude of their insertions. All this variety *Arantius* doth very wisely ascribe to the admirable wisdome of Nature, who hath therefore intertexted and wouen one within another these Muscles of the Backe, yea rather allowed them continuall and indiuisible particles, that they might the better sustaine and accomplish those strong and violent actions ouer which they haue the command. For if power vnited be the stronger, then certainly if many Muscles doe conspire together into one motion they will bee better able to absolue it. The Muscles therefore of the Backe together with the racke-bones were made to rayse vp and there to hold the whole bulke of the body, which is established on the holy-bone as vpon his foundation. We say therefore with *Galen* in the 14 chapter of his Booke *de dissect. muscul.* that because these muscles cannot by any meanes be truly separated, either there must bee so many payres as there be racke-bones, or else we must say that there is one onely payre offering tendinous distributions to all the *vertebrae*. And of this payre if one Muscle worke, the Spine is extended and inclined into his side; when they both worke equally, the Spine bending on neither hand by reason of their intention or remission is recurued backward.

Why the muscles of the backe are so wouen together.

But whereas almost all Muscles haue their Antagonists, that is, the authours of a contrary action to theirs (and therefore haue experience of their mutuall action and passion with an interposition of rest in the middle figure) yet notwithstanding these muscles of the Spine (if you except the bending Muscles of the necke) haue no Antagonists or contraries.

They haue no antagonists.

For because the inner Region of the Chest and the Loynes are destinated to those most noble entalles which serue for Respiration or Nourishment, it seemed not good to Nature to aduenture to prejudice or impeach their actions by any instruments of voluntary motion.

Whence

Four pairs
of the backe.

Whence it is that when these Muscles are relaxed (as they are in old men as well by reason of the waight and weaknesse of the body, as also because they abound with Phlegmatick humors) they are not able to containe or hold the body vpright. Norwithstanding Anatomists, because they haue obserued especially in Dancers and Tumblers, that the backe is moued forward, backward, to the sides, and almost semicircularly, they haue resolved that for the performance of these motions there are on either side foure muscles, *Laurentius* maketh ten, *Siluius* but fixe.

The first payre are called *Quadrati* the square muscles, [tab. 14, 22, tab. 11. and 29, 2] they arise broad, thicke and fleshy from the backward and vpper cavity of the haunch-bone, and from the inner and vpper of the holy-bone, and lye as it were square vpon the racks of the loynes, vpon which they climbe on the inside of the *Abdomen*. There they are a little streightened and cleauing to the transuerse processes of the racks of the loines are fleshy inserted into the lower part of the twelfth rib.

The fibres of this muscle doe ascend from without inward and obliquely vpperward, and those which proceede from the holy-bone are inserted into the lowest rack of the loines: the rest of the fibres which succede these toward the haunch-bone, doe by degrees determine into the vpper racks, so that in the whole course of this muscle the fibres are inserted to the transuerse processes of the racks of the loynes, and to their sides.

Their vse is to bend the racks of the loynes or the lower part of the backe with the right motion forward, but if one of them worke alone, then is the flexion oblique and the backe, downe to one side and together forward. The forme of this muscle in dogs and apes differeth much from his forme in men.

[Table 29. is the same with Table 12. of this booke.]

Position.

The second payre called *Longissimi*, [Tab. 12. 11, 12] are indeed the longest muscles in the whole body of man, for they reach from the lower end of the *holy-bone* vnto the first racke-bone of the chest, sometimes to the mamillary proceffe of the temple bones. They are like the fift paire of muscles of the chest called *Sacrolumbi*, [tab. 11, 1] to which in their originall and their proceffe thorow the loynes, they do grow as if they were a part of that paire. They are also the largest of all the muscles of the backe.

They arise with a very neruous, strong, & acute originall [Tab. 12.] from the top of the spine of the *holy-bone* [tab. 11. L.] passing through his length and from the spines of the five rack-bones of the loynes.

In the inside of the haunch-bone [table 29. 6] where they are ioyned to the *holy-bone* they produce a neruous original, saith *Fallopins*: a fleshy, saith *Vesalius*, vnder which neruous original as vnder a certaine ligament or couering lurketh another originall very fleshy.

Termination.

From hence ascending at the outer-side they become fleshy and are inserted into the transuerse processes of the racke-bones of the loynes: as also into all the transuerse processes of the racke-bones of the chest, growing by degrees narrower from the eleuenth vnto the first, where they offer one neruous tendon on the inside like a neruous handle, [tab. 11. MM] which is spread vpperward obliquely toward the outside, like as the muscles called *Sacrolumbi* did from the out-side offer a tendon along all the ribs. Sometime also they determine into the first *vertebra* of the chest: sometime departing from the processes they ascend vnto the mamillary proceffe of the temple-bone and there end.

A sinus in
them.

On their inside because of the thicknesse of the fleshy part and the tenuity or slendernesse of the neruous, there is grauen through their length a certaine *Sinus* or bosome, [tab. 26, be-
twixt *a* and *a*] to giue way to the third muscle of the backe which is called *Sacer*.

Their vse is directly to extend the backe and the loynes if they bee contracted together. *Columbus* and *Archangelus* thinke that they bend the whole backe and head also backward, so that our body thereby may be compassed into a halfe circle, which kind of Posture wee may see in Tumblers when they play their feates. But if one of them onely bee contracted, the spine is extended on one side, for their fibres are oblique.

The third paire are called *Sacri*, or the holy muscles, [tab. 29, 2] They lye vnder the former. They arise both touching one another, [tab. 29. X] with an acute originall from the vpper part of the holy-bone where the spine is fastened with the haunch-bones; as also from the transuerse processes & the roots of the spines of the racke-bones of the loines, [tab. 19, 8] or if you please, say with *Fallop.* that they ascend from these processes and are increast with diuers

diuers originalls; as also from the racks of the Chest, and that with a threefold originall, one higher from the end of each transuerse proceffe; another lower, as it were from the roote of the same proceffe, the third from the Spines of each racke bone: so that they seeme to bee three kinds of Muscles mixed together; one outward hauing long fibres, another inward hauing short, a third hauing yet shorter which ariseth from the Spines. After their originall they grow brode by degrees, but before their termination which is acute and made into the Spine of the twelfth, sometimes of the eleuenth spondell of the Chest, they become slender. Their fibres run obliquely vpward and inward. Their vse is, if they worke together and contract their fibres to extend that part of the Spine to which they are fastened. But if one of them alone worke, it extendeth a part of the backe obliquely, and putteth the body on the one side into a semicircular forme.

Termination
and vse.

The fourth paire are called *Semispinati*, [tab. 10. 11. 20. 25. A] they arise with an acute originall from the Spine of the twelfth racke bone, sometimes of the eleuenth of the Chest; and arising vpward by degrees they grow thicke and fleshy, especially at the Spine of the fifth racke of the Chest being intertexted or wouen with neruous fibres: they imbrace all the spines of the racks of the same. Presently after they become attenuated and doe determine with an acute end into the Spine of the first racke bone of the Chest. Their fibres are most what right. These Muscles as also the former paire doe fill vp the distances betwixt the Spines, where they are contiguous, that is, touch one another. And nothing beside a membranous ligament issuing from the vpper Spine into the lower commeth betweene them.

Originall.

Termination
Fibres.

Their vse is to gather together the Spines whereinto they are inserted, and to extend or lift vp that part of the backe to which they grow; or the backe properly called *Dorsum*, together with other Muscles, the loynes being vnmooued. When one of them onely worketh it mooueth the backe to the side; but when all eight Muscles conspire together, the whole backe is bowed directly downward. If foure worke together so as one follow another, they mooue it into a semicircle: but if the Muscles that be on the one side do worke alone, the body is inclined to that side. And thus much of the Muscles of the backe.

Their vse.

CHAP. XXXVI.

Of the Muscles of the Fundament, the Bladder, the Testicles and the Yard.

BEcause Man was a politique creature, made for Action and contemplation, it was fit that he should either receiue his nourishment, or auoyde his excrements perpetually as plants doe, but at his owne choyce. As therefore in the Chops there are Muscles seruing for digestion or swallowing, so in the end of the guts and the outlet of the vrine, there are Muscles set as porters to interclude the passage vnlesse we list to open it.

The spincters.

The Muscles therefore of the Fundament are foure, two *Sphincters*, and two *Leuators*, one of the spincters is fleshy [tab. 30. fig. 1. E] arising from the lower racks of the holy bone, and like a ring is so implicated with transuerse fibres to the extremity of the right gut, that it altogether shuttereth the Fundament. The other spincter is fleshy, and in my iudgement, saith *Laurentius*, seemes to be nothing else but hardened skinn wouen with fleshy fibres, therein following *Galen* in the thirtieth chaptet of his Booke de dissectione musculorum: *Falkopius* also is of the same mind, yet *Banbini* maketh but one Muscle of these two, which saith he, is tyed on the backe side to the rumpe bone, on the fore side with fibrous ryes to the outlet of the Bladder and to the Yord, to whose Muscles it affordeth an originall as also to the necke of the wombe. At the sides it is tyed with round ligaments produced out of the holy-bone vnto the haunch-bone, and is strangely commixed with the insertion of the *Leuators*.

Two leuators

The two *Leuators* [tab. 30. fig. 1. B C] doe lie vnder the Bladder, they are small Muscles, but neruous and broad arising from the ligaments of the share, haunch and holy bones, thence descending they reach vnto each side of the seate where they compass the gut, and

[Table 30. is the same with Tab. 12. in the 3. Booke.] are inserted into the vtter coate thereof, and the vpper part of the spincter, [tab. 30. fig. 1. E] a portion of them also groweth to the roote [tab. 30. fig. 1. D] of the Yord, and the necke of the Wombe. Whence it is that some haue made them three Muscles.

Their vse.

Their vse is after excretion to retract the Fundament, and if these Muscles bee weake or

Cccc

resolued,

resolved, then followeth that disease which they call *Ani-procidens*, or the falling of the Fundament.

Of the bladder.

The Bladder also hath a spincter Muscle seated in the beginning of his necke, from which it cannot be distinguished, and indeede it is nothing else but a more fleshy substance of the sayd necke woven with many transverse fibres, by which it is constringed. If this Muscle be either relaxed or refrigerated or wounded, the Urine followes against our willes. In women it is thicker then in men, because there be no prostate Glandules.

Of the Muscles of the Yarde we haue spoken before in the 8 chapter of the 4 Booke, which it shall not neede to repeate. Onely we remember that they are foure, two collaterall, and two called *Inferiores* or the lower muscles.

Of the Muscles also of the Testicles we haue spoken before in the 4 chapter of the 4 Booke. Remember onely that they are two and called *Cremasteres* or the suspending Muscles. Now we descend vnto the Muscles of the Legge.

CHAP. XXXVII.

Of the Muscles of the Legge.

Ecause the Muscles of the Thigh cannot bee demonstrated before the Muscles of the Legge are viewed, wee will first speake of the Muscles of the Legge, following therein the order of Dissection. The Legge therefore is that part of the Foote in the large acception, which is betwixt the knee and the Foote properly so called.

What the leg is.

It consisteth like the cubit of the bones: the one beareth the name of the whole and is called *Tibia* the Legge; the other is called *Fibula*, we may call it the *Brace-bone*. Now the Legge is mooued either by it selfe or by accident with three motions, for it is bent or extended directly, and it seemeth also to be mooued obliquely outward. It is bent by five Muscles, extended by foure, one onely mooueth obliquely. By accident the Legge is mooued after the Thigh, and that is either to one side or about. First we will entreate of the Benders.

His motions And number of his muscles.

The first.

The first Bender or the longest [*table 31, and those that follow, figure 1, 2, 4, 7, 8, a*] with which we meete on the foreside presently vnder the skiane; ariseth with an acute [*Fig. 1, 3, 7, 4*] neruous and fleshy originall from the inner appendix of the haunch-bone, presently becomming fleshy it runneth with a decussation like a slope swathe thorough the inside of the Thigh, being very slender and lying vpon the other Muscles. Neare the bone it is yet narrower [*fig. 1, 2, 7, 8, b*] and endeth in a neruous Tendon, which is inserted in the fore and inside of a sharpe line which is in the bone of the Legge [*Table 7, c, is the insertion of the first second and third Muscles of the Legge.*] His vse is the same with the two following, that is, to bend the Legge inward, and withall to lift it vpward.

The 2 muscle.

The second Muscle of the Legge which is also called *gracilis* or the slender Muscle, [*table 31, and those that follow, Fig. 1, 2, 4, 5, 7, 9, b*] is situated, (especially the belly of it) in respect of the former inward and so lyeth close vnto it. It ariseth with a neruous and large originall [*fig. 2, d, e*] at the meeting of the share bones to which also it groweth, and is as big and large as that commissure or meeting is: Afterward it becommeth narrower but more fleshy, attayning through the inside of the thigh vnto the knee it determineth into a Tendon exactly round at the inner head of the Thigh, not farre from the knee; where also the Muscle becommeth round before the Tendon grow from it. When the Tendon is a little dilated it is inserted into the Legge neare the first Muscle but a little more inward, and it is of the same vse with the former.

The third

The third bending Muscle which is called *Semi-neruosus* halfe sinewy, [*tab. 31, and those that follow, fig. 2, 3, 4, 5, 6, c*] is seated on the backside, and ariseth from the vpper part of the protuberation of the haunch-bone [*fig. 5, 6, f*] where it is neruous and slender, but about the middle of the Thigh it becommeth fleshy and maketh a rounde muscle, which descendeth a little obliquely by the backside and inside of the Thigh, at whose inner head it is reflected and attenuated [*fig. 5, g*] and inserted with a round tendon in a man (in Apes sometimes it is broad) into the forepart of the Legge, where also the two former were inserted, but the Tendon of this third descendeth vnto the middle of the Legge.

The fourth.

The fourth bender is called *Biceps* or the double headed muscle. [*tab. 31, and those that follow, fig. 1, 3, 4, 5, 6, 10, 13, d*] It ariseth with a neruous acute and slender originall, [*fig. 6, h*]

out

out of the lower part of the haunch-bone or out of his protuberation. Presently after it becommeth fleshy, and descending through the vter and backside of the thigh in the inside thereof about the middle where it appeareth nervous) it receiveth a fleshy portion [fig. 6, k] as it were a new Muscle arising out of the middle of the thigh whereby this Muscle is strengthened; for the outward part there is onely this one muscle, but on the inside there are foure. This portion is so mixed with the muscles when it produceth his Tendon, as if another muscle did therefrom arise. [fig. 6, k, s] Wherefore it may be numbred for one or for two muscles. A portion increasing it.

Both these descending and on the outside nervous, do end in a notable Tendon which is implanted into the acute proceffe of the *fibula* or the *Brace*. [fig. 10, d] For the behoefe also of this Tendon, the head of the Thigh hath a long externall *sinus* or cavity cruised ouer with a smooth and slippery Ligament wherein it is securely conueyed, and beside, least bending obliquely that way it should go out of his tract.

The first bender is called *semi-membraneus*, that is, the halfe membranous Muscle. [tab. The fifth, 31, and those that follow, fig. 2, 3, 4, 5, 6, 13, 14] It runneth through the backside of the thigh, and ariseth with a nervous and acute originall from the appendix or protuberation [fig. 6, m] of the haunch-bone neare the head of the third Muscle. [fig. 6, f] It continueth nervous longer then any Muscle of the body, but at the middle of the Thigh it beginneth to bee fleshy, and in his lower part thicke, and neare the knee endeth into a round Tendon, [Figure 6] wherewith (a little dilated) it is inserted into the inner side of the Leg, with the first second and third Muscles. This Muscle also being very liuid in the backpart beyond the middest hath a bosome or cavity in it, [fig. 6, n] whereupon the forepart of the third muscle leaneth, & in his whole course applyeth it selfe thereto, so that they appeare to be but one Muscle.

The sixt muscle of the Legge or the first extender which is called the *membranous Muscle*, [tab. 31, and those that follow fig. 1, 2, 4, 7, 8, 1] occupyeth the outward and middle part of the Thigh, and ariseth [Fig. 1, 4, 7, p] fleshy and sharpe from the Spine of the haunch-bone: and being conueyed to the ioynt of the hip (at which place onely it is fleshy) and becomming narrower it departeth neare the outside of the greater proceffe of the thigh, into a very long and broad [Fig. 7, *] membrane of the nature of a tendon, then which there is no greater in the whole body, for like a skinne or a transuerse Ligament it compasseth almost all the muscles of the thigh (but it is not in all places alike thicke) and holdeth them in their proper seates (as we saide before the muscles in the cubit were inuested) and incloseth also the ioynt of the knee. This Tendon at his insertion is mixed with the Tendons of the following muscles, and is infixed into the forepart and vter side of the Legge. His vse is to extend it directly and to mooue straight forward. The sixt or the first extender.

The seauenth or the second Extender, which is also because of his greatnesse called *Vastus externus*, *The Vast Externall Muscle*, is wholly liuid [tab. 31, and those that follow fig. 1, 3, 4, 5, 6, 8, 9, 10, 13, H] and occupyeth the outside of the thigh, as also a great part of the fore side and the backside. It ariseth [Fig. 9, r] with a broad large and nervous originall from the outside of the Thigh, and compasseth round about the roote of his great proceffe growing thereto. Presently after the originall it becommeth thicke and fleshy, and lying vppon a part of the eight, it is wholly fleshy, and a little about the whirle bone of the knee [Fig. 9, x] it endeth into a large and membranous Tendon, which being mixed with the Tendons of the two following muscles, descendeth at the outward side of the same whirlebone which it doth encompassse; and is inserted [Fig. 9, u] into the fore side of the Leg immediately vnder the ioynt. The seauenth.

The eight or the third Extender which is called *Vastus internus*, *The Internall Vast-Muscle*, [tab. 31, and those that follow, Fig. 1, 2, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14, 0] compasseth (on the inside) almost all the circumference of the Thigh-bone. It ariseth fleshy from the necke [fig. 10, y] of the Thigh, and presently becomming fleshy, a portion of it groweth out of the roote of his greates proces as if it had a double originall. This latter originall (if you list so to call it) descendeth large and oblique, and becomming by degrees more fleshy it buncheth or beareth out at the inside of the thigh neare the whirle-bone into a thicke and fleshy semicircle, out of which groweth a strong tendon which occupyeth the whirle-bone also. [Fig. 9, u] This portion some do make a distinct muscle and call it *Crurium*. [Fig. 2, 7, 8, 9, Z] This muscle with the former maketh a *sinus* or bosome very liuid, [Fig. 9, char. 1] that the subsequent muscle might lye vppon it throughout his length. The eight.

The ninth or the fourth extender called also the *right Muscle*, [Tab. 31, and those that follow fig. 1, 2, 3, 4, 7, 8, 9, x] lyeth on the outside vppon the first bender, and is seated on the mid-

middest of the forepart. It ariseth with a nervous and acute originall [Figure 8. character 1.] from the internall protuberation of the haunch bone on the fore-side about the Cuppe of the Coxendix. From thence it is deriued directly through the length and forepart of the

Table 31. With those that follow, shew the sixe Muscles of the Legge, the Thigh, and of the foote. Fig. 1. sheweth the foote and musculous part of the left Thigh. Fig. 2. sheweth the internall and laterall part of it. And Fig. 3. sheweth the externall laterall part of it.

TABVLA XXXI.

the legge, called *Biceps* or the double headed muscle. *a* 1, 2, 3, the first muscle bending the legge called *membranosus*. *z* 1, 2, the first muscle extending the legge called *Vastus externus*. *9* 1, 2, the third muscle extending the Legge called *Vastus internus*. *u* 1, 2, 3, the fourth extender of the Leg, or the *Right* muscle. *u* 3, the first extender of the thigh, called *Gluteus maior*. *o* 2, the inner ankle. *o* 1, 3, the vtter ankle. *q* 1, A fleshy part of the first extender of the Leg. *q* 2, the first extender of the thigh called *Triceps* or the three headed muscle. *o* 2, the first bender of the thigh called *Lumbalis*. *r* 2, the second bender of the thigh called *Iliacus*. *v* 1, the third bender of the thigh. *z* 1, 2, the first extender of the foote, or the internall *Gastrocnimius*. *p* 1, A portion of the second extender of the toes, which *Vesalius* maketh the ninth muscle of the Foote. *q* 3, the greater proesse of the thigh called *Rotator*. *r* 3, the transuersel ligament reaching from the brace to the heele. *r* 2, A portion of the 5 muscle of the thigh, *x* 2, the bone of the Legge bare. *7* 1, 3, the tendon of the first extender of the toes. *z* 1, 3, A transuersel ligament above the foote.

A A, The holy-bone.
B 2, A ligament drawne from the holy-bone vnto the hip.
G 1, 2, the state of the holy-bone.
H 2, the third Muscle extending the soale called *Plantaris*.
I 1, the fourth muscle extending the foote or the soale muscle.
K 2, the fift muscle extending the foote, called *Tibialis Posticus*.
L 1, the first muscle bending the foote called *Tibialis Anticus*.
M 1, 2, the second bender of the foote called *Peronaeus primus*.
N 3, the third bender of the foote called *Peronaeus secundus*.
P 1, 3, the second extender of the toes, or the stretchers.
R, the second bender of the toes, or the great bender.
T 1, 2, the lower abductor of the great toe.
V 3, the abductor of the little toe.
** 2*, Tendons carried vnto the toes of the foote.
X 2, the internall part of the fourth muscle of the thigh as it were three-fold, at *a, c, f*.
Y 1, the vpper abductor of the toes.
a c f, A part of the tenth muscle of the thigh as it were three-fold at *a c f*, and carried vnto the great proesse of the thigh.
z 2, A greates nerue lying vppon the tenth muscle between *x* and *a*.
a 1, 2, the muscle of the Legge, or the first bender which is the longest muscle.
a 1, 3, His originall.
b, 1, 2, His tendon.
9 2, 2, the muscle of the Legge or the second bender which is the slender muscle.
d 2, His originall. *d* His tendon.
7 2, 3, the third muscle bending the tibia called *Seminernus*.
9 2, 3, the fourth muscle bending

thigh

thigh betwene the seauenth and the eight Muscles, and being by degrees increased with a fleshy substance it becommeth againe by degrees more slender about the middle of the thigh. [figure 8, character 2.] and determineth into a very long and exceeding strong tendon about the whirle, where it is a little narrower and more slender. But in the forepart of the whirle it is againe dilated, and being mixed with the tendons of the two forenamed muscles is very strongly inserted into the Legge on the foreside immediatly vnder the ioynt. But in Munkies, it is most what membranous and inserted into the Legge much lower. Neither this onely, but also the tendons of the other muscles are more membranous and broder in men then in Apes. And with this tendon of the three muscles is the whirle bone couered, yea it groweth to his forepart, and seruerth the knee for a ligament. This is the Muscle which is like a Snake or the fish (because of his broad taylor) which is called *Mus* or the *Mouise*, which vibereth the Whale that he offend not against the rockes, from which fish the Muscles of the whole body haue their denomination.

The tenth and last muscle of the Legge is called the *oblique moouer*, and from his situation *popliteus* the muscle of the Ham, [tab. 34, 38, figure 14, 16, 28, 29.] for it lurkes in the ham vnder that Muscle of the foote which is called *Gastrocnemius*, and *Plantaris* next of all to the bones, and therefore we cannot meete with it before these bee remooued. It is a short and slender Muscle and issueth with a neruous [fig. 16, character 4] and round originall from the externall head of the thigh, after it is increased with fleshy fibres and running vnder the ligament, climbing obliquely ouer the bone *Tibia* or the Legge, determineth broad and fleshy and is inserted into the backe and inner part of the Legge at his appendix. [tab. 31, character 5.] His vse is to mooue the Legge obliquely outward, and therewith also to turne the foote somewhat inward toward the other, for the foote is specially articulated with the Legge bone, and therefore *Galen* sayd that it was the principall author of the bending of the Legge.

CHAP. XXXVIII.

Of the Muscles of the Thigh.

HE Thigh is that part which is betwixt the ioynt of the huckle bone and the knee, and consisteth of one bone as doth the arme. This part because it is mooued according to our good pleasure by reason of his round head, and that with all kind of motion, it stood in neede to haue Muscles and those very many.

These Muscles doe mooue the thigh either directly or in compasse. Directly, either lengthwise or ouertwart, and that eyther by extention or by flexion. It is extended either when we stand vpriight and make (as we say) a curtesie, bending the thigh moderately inward and downeward toward the earth: Or backward into the posterior part when we lift our thighs vpward, especially toward the outside, which kinde of position may be seene in that they call a *Backe-caper*. This extention is made by the helpe of five Muscles, which most what doe occupie the posterior part. And the first foure of these doe lie vpon the huckle bone, and the fifth vpon the thigh.

The thigh is bent when we lift it vpward and forward, and especially toward the inside; (in extension it is toward the outside) as it is in Anticke dances, and this motion is performed by three Muscles situated before; two of them are seated in the cavity of the belly, and the third in the thigh.

The circumaction or compassing of the thigh is either inward or outward, and performed by three Muscles placed in the coxendix. Wee conclude therefore that there are eleuen muscles of the thigh, although I know many more may bee named if wee diuide the fifth muscle into foure; make two of the fleshy pouch which compasseth the tendon of the tenth Muscle, and adde the twelfth Muscle described by *Arantius*: for then each thigh shall haue seuenteen Muscles which shall extend it, bend it, leade it in compasse, draw one thigh to another, diuide them asunder, or lift one thigh ouer another, as Taylers vse to sit at their worke. Of all which motions we will speake in order.

The first extender is called *Gluteus maior* the greater buttocke muscle, because it maketh almost all the buttocke on one side; [tab. 31, and those that follow 3, 4, 8, 9.] for it is thicke and

Cccc 3

fleshy

fleshy and lyeth iust vnder the skin, being appoynted with the two following to make the quillion of the seare.

It ariseth with a fleshy broade and semi-circular originall, from the whole circumference of the haunch bones, from the lower part of the holy bone where it is contiguous with his opposite, and from the beginning of the rumpe-bone. [tab. 32, figure 4, a b c] Afterward descending a little obliquely and riding over the ioynt of the huckle-bone (which it strengthneth, as it were, with a couering) it becommeth narrow and more slender, and so

Table 32. Skeweth especially the Muscles of the Thigh and the Legge.

a b c 4, the originall of the first extender of the thigh. d e, His insertion. f g, 5, 6, the originall of the third bender of the Legge called *Seminervosus* at f, the beginning of his tendon at g. i k, 5, the semicircular originall of the second extender of the thigh at b: His insertion into a proceffe of the thigh. h 6, the head of the muscle called *Biceps*, or the fourth bender of the leg. k 6, A fleshy portion whereby it is increased. H 4, the fourth extender of the foote called *Plantaris*. l 5, A portion of the fifth muscle extending the legge, or the muscle called *Semimembraneus*. m n o 6, His head m. The beginning of his tendon o. A bosome or cavity in which the third extender of the legge doth rest. n. r 4, A fleshy part of the extender of the Legge, called *membranosus* at p His originall. p 6, the backe of the haunch-bone bare. s x 6, the circumscription of the third bender of the thigh. s 6, the insertion of the third and fourth extenders of the thigh. t 5, 6, the great and vter proceffe of the thigh. u 5, 6, A ligament going from the holy-bone into the acute proceffe of the hip. v 5, A ligament going from the holy-bone into the backe-part of the hip. y 5, the fourth nerue which is the greatest nerue of the whole legge, wherein is the tumor collected which causeth the hip-gowte. * A sinus or cavity wherein the great veyne of the Legge and the artery together, with the nerue are conueyed. 1, 2, character 6, the fourth nerue parted into two in the ham, the greater branch 1, the lesser 2. 34, character 6, the membranous beginning of the oblique ascending muscle of the *Abdomen* from the spine of the backe. 8, 9, character 6, two fleshy portions, or the fleshy pouch, and leaning to the second *Circumactor*, or compassing muscle of the thigh.

44, The first Muscle of the leg called *Longissimus*.

45, the second muscle of the legge called *Gracilis*.

45, 6, the third bender of the leg called *Seminervosus*.

45, 6, the fourth bender of the leg called *Biceps*.

45, 6, the first bender of the Legge called *Semimembraneus*.

4, the first extender of the Leg called *Membranosus*.

45, 6, the second extender of the Legge or the muscle called *Vastus externus*.

45, 6, the third extender of the leg called *Vastus internus*.

4, the fourth extender of the legge called *Rectus* or the Right muscle.

45, the first muscle extending the thigh called *Gluteus maior*.

45, the second extender of the thigh called *Gluteus medius*.

6, the third extender of the thigh called *Gluteus minor*.

5, the fourth extender of the thigh called *Iliacus internus*.

4, 6, the fifth extender of the thigh called *Triceps* or rather *Quadriceps*.

6, the hinder part of this muscle.

x 5, 6, the first circumactor or the muscle leading the thigh about, called *Obturator internus*, together with fleshy portions both above and below growing vnto it.

4, the first extender of the foote called *Gastrocnemius internus*.

4, the second extender of the foote called *Gastrocnemius externus*.

endeth into a strong and broad tendon, which is partly inserted into the roote of the greater proceffe, partly below it into the outside of the thighbone, and that obliquely.

The vse of this muscle is when it worketh all together to settle the thigh backward and to extend it directly; for if but one part of the muscle bee contracted, then the motion is not equall but more outward to this or that side.

The second extender which is called *Gluteus medius*, the middle buttocke muscle [table 32. and those that follow figure 4, 5, 8, 9, v.] lyeth for the most part vnder the first. The rest of it is couered with a membrane. It is also like the first in forme, but lesse and very liuide, as also is the third in leane bodyes, but in those that are fat especially in women wee often finde neruous fibres running through them to which fat groweth, to make the seate the softer. It ariseth with a fleshy, broad and semicircular originall, [table 32, figure 5, b i] (a little lower then the first to whose originall it giueth way) from the ridge of the haunch-bone on the fore-part and from the backe of the same haunch, and indeede it occupieth almost all the circumference of that bone; thence descending obliquely it groweth narrower by degrees, runneth vnder the forward muscle, couereth the ioynt of the hippe, and determineth into a broad, strong and membranous Tendon, [figure 5, k] which is implanted into the fore and vpper part of the great *Trochanter* or proceffe of the necke of the thigh, which it compasseth on euery side but ouerthwart. His vse is to extend the thigh and to draw it vpward and forward vnto one side, and that more manifestly then the former muscle. The fibres also of this muscle make a decussation with the fibres of the former, [table 5, u with v.]

The second.

The third Extender called *Gluteus minor*, the lesser buttocke muscle [table 32. and those that follow Figure 6, 10. &.] lyeth wholly vnder the second, and is so much lesse then it, as the second is lesse then the first. It ariseth from the backe of the haunch-bone, and from his backward and lower part where the bone of the coxendix beginneth; and his originall, (as the two former) is fleshy, thicke and semicircular. [Figure 6, q s x.] Then declining downward and forward, it cleaueth easily with fibrous ryes to the ligament of the ioynt of the hippe and becomming narrower determineth into a broad and strong Tendon, which climbing ouer the greater *trochanter* or proceffe of the thigh, is implanted into the very top of his forepart, where it is a little inuerted. [Figure 6. f.] His vse is to drawe the thigh moderately vpward and backward, and so to extend it.

The third

The fourth extender called *Iliacus externus pyriformis*, the outward haunch peare muscle [tab. 32, Figure 5, 6, and table 34, Figure 1, 3. &.] because it filleth the outward and lower cavity of the haunch-bone with his oblique position, and like a round peare. This muscle is liuide, and ariseth with a fleshy and round originall from the three lower racks of the holy-bone, or from the inner part of the sides, where sometimes it is continuall with his opposite: thence it runneth downward but fleshy and ouerthwart to the great *trochanter*; but before it touch the thigh it becommeth narrower and endeth in a round tendon, which is obliquely implanted into the greater *trochanter* or head of the thigh on the backside neare his appendix. His vse is to draw the thigh moderately vpward and backward, and so to extend it. It is also some little helpe to leade the thigh round but forward, yet more then the third muscle.

The fourth.

The fift extender is commonly called *Triceps* because it hath a threefold originall, but may better be called *Quadriceps*, for his originall or rising is fourefould. [table 31. and those that follow figure 2, 4, 6, 8, 9, 10, 11, 12, 13, 14. & p.] This is the thickest Muscle in the whole body of man, and stuffed with a wonderfull variety of fibres, insomuch that because the parts thereof doe differ among themselves in their originall, fibres, insertion, coates, and in some sort in their vse likewise, *Fallopins* saith, and so may wee also, that there are so many muscles as there are parts of this muscle, to which also the *Right* muscle which seemeth to bee a part thereof must bee referred, whose originall is seated vnder the three heads of the Muscles which make the bulke of the Legge. [tab. 32, Fig. 6. f h m] But we will here vnder exhibite his description according to *Fallopins*.

The fifth.

The thickest muscle of the body.

The first part [tab. 35, Figure 12, a part of the Muscles is at v] ariseth with a neruous originall from the vpper line of the shere-bone, and descending is inserted into a rough line of the thigh vnder the middle. Notwithstanding from his tendon proceedeth a slender portion which is vnited with the tendon of the fourth part and is inserted into the lower head of the thigh, and the inside of the knee.

The second part [table 35, and 34, Fig. 13, and 14, character 6] ariseth from the lower parts of

of

R 9, the 2 bender of the toes called *Flexor magnus*. T 7, the lower abductor of the greate toe. X 8, 9, the bone of the Legge bare T 8, 9, the vpper abductor of the toes. Z 7, 8, the muscle called *Cruicicus*. J 7, The first extender of the Foote called *Gastrocnimius internus*.

of the commissure of the share-bones where they are ioyned together. It is fleshy and broad and hath oblique fibres, descending also downward, it is implanted into the line of the thigh in the vpper part thereof.

The third part [Tab. 34. fig. 13. char. 6. fig. 14. char. 7. conferred fig. 13. 30^u. among themselves] ariseth with a fleshy, sometimes a nervous originall from the appendix of the *Coxa*, yea from the whole coxendix round about the circumference of his broad hole; his fibres are very diuers, so that it seemeth to be a double Muscle, for the vpper fibres are as it were transuerse, but many of the lower oblique. This part descending is inserted into a rough line vnder the little trochanter or head of the thigh.

The fourth part, [Table 34. fig. 12. and 13. r x y] ariseth with a nervous [figure 13. u] and then fleshy [x] originall from the appendix of the *Coxa*, which two originals forme a Muscle

Muscle whose belly is dilated into a strange breadth; [Fig. 13.] afterward running along the backside of the thigh, it endeth into a round tendon [Fig. 13, under 2] which with a slender portion of the Tendon of the first part is inserted into the inner and lower protuberation of the thigh. [three parts of this Muscle are demonstrated, tab. 36, 12, & v. where they hang down also. Tab. 34, Fig. 14, 6, 7.]

The use of this muscle although it be to lift up the Thigh and leade it to the body: yet according to the diuersity of his partes it hath diuers particular offices: for the backe part which hath right fibres, establiseth the thigh and fasteneth it vpon the ground being extended, as when a man setteth his foote to passe forward. The backe portion also of the anterior part performeth the same, but it leadeth the thigh moderately inward as it were to the other thigh, so the first part of the anterior leadeth the thigh inward and crosseth one thigh ouer another. And thus much concerning the extending Muscles, which primarily extend the thigh, and these also doe helpe it when it is moued sidelong or ledde about.

These of the
5. Muscle.

The Bending Muscles are three: The first is called *Lumbalis* [tab. 31, and those that follow Fig. 2, 8, 10, 11, 12, 14, 16, chara. 6] the Muscle of the Loynes which *Hippocrates* and *Galen* called *ΐσας*. They are placed a little obliquely into the cavity of the *Abdomen*, and when the entrails are taken forth they presently appeare in the Loynes. It is a round, fleshy, thicke and strong Muscle, and altogether liuid. It ariseth fleshy [tab. 35, Fig. 12, a] from two lower racks of the Chest, and the three vpper of the loynes: presently after it climbeth ouer the rest of the racks of the Loynes, and descending fleshy by the haunch-bone [from a to b] it runneth a little obliquely and something outward about the share-bone, and so determineth into a strong and round Tendon which is inserted on the fore side at the vpper part of the lesser head of the thigh. His use is strongly to drawe the Thigh vpward and to bend it inward. And because the tendon of this Muscle should be securely conuayed, not hurt by the hardnesse of the bone, nor yet erre or wander out of his way, there is a *sinus* or cavity insculped in the share-bone which is couered ouer with a membranous, smooth and slippery Ligament arising out of the bone. And because the kidneys lie vpon this Muscle ouer which a notable nerue is disseminated; hence it commeth to passe that those that are troubled with the stone in the Kidneyes doe finde a *stupor* or sleepinesse on the Thigh on that side the stone is on.

The first bending
muscle.

The second Bender is called *Iliacus internus* the inward haunch-Muscle. [Table 31, fig. 2. & Tab. 33, fig. 10, 11, 12, 16, T] At the lower part it toucheth the former Muscle [tab. 35, fig. 11, 12, T, as farre as c] and occupyeth all the inner cavity of the haunch-bone. From thence as it were out of a semicircle it ariseth fleshy and broad and by degrees becommeth narrower and thicker, and descending forward about the vpper part of the *Coxendix* it is implanted with a round tendon [Ta. 34, fig. 14, T] into the lesser head of the thigh like as the former, but somewhat lower then the first bender. His use is together with the first Bender to lift the Thigh vpward and so to bend it, but this Muscle mooueth it lesse inward. And whereas it is carried about the *Coxendix*, the bone hath in it a smooth and slippery cavity for the better conueying thereof, which cavity where the Muscle bendeth is liuid, nervous and strong, the better to defend it selfe against the hardnesse of the bone.

The 2 Bender.

The third Bender [tab. 31, and those that follow, Fig. 1, 7, 10, 11, 12, v] is also liuid, and ariseth broad and fleshy from the Line of the share-bone, hard at his gristle and runneth obliquely within the first extender, so that some haue accounted it for a first part of the same first Muscle and so determineth into a short, broad and large tendon which is inserted at the inside of the Thigh ouer against the lesser head and runneth out vnto the backside. His use is to leade the Thigh vpward and inward very strongly and so to crosse one Thigh ouer another. And so much for the benders of the Thigh.

The 3 Bender.

The first compasser which is called *Obturator externus* the outward filler [table 35, Figure 12, 14, 16, e] lyeth vnder the former and filleth vp on the outside all the hole which is before in the share and the haunch-bones. The forme of it is like a Peare as was the fourth extender. It ariseth fleshy and broad from the circumference of the foresaid hole, and on the fore side is liuid. It runneth ouerthwart and behinde by the hip ioynt away and the necke of the thigh, there it is by degrees angustated and determineth into a strong and large tendon, which is implanted into a cavity of the greate *trochanter* or the head of the thigh. His use is to turne the thigh inward, *Laurentius* sayth outward.

The first compasser.

The second compasser *Obturator internus* the inward filler [Table 31, and those that fol

The 2 compasser.

14, A tendon made of three muscles of the foot. Tab. 14. Sheweth the Muscles of the thigh and of the foote.

14, The beginning of the tendon of the first *Peroneus* out of the middle of his body.

14, The tendon of the second *Peroneus* reflected to the outward ankle.

13, the fourth bending muscle of the leg called *Biceps*, hanging downe.

13, the fifth bender of the leg called *semimembranous* hanging downe.

15, A ligament in the sole of the foote serving in stead of the broad tendon.

13, the second extender of the legge called *Vastus externus*.

13, 14, The third extender of the legge called *vastus internus*.

13, 14, An acute Ligament going from the holy bone into the proesse of the hip bone.

14, the muscle called *popliteus* moving the legge obliquely.

13, A portion of the third muscle extending the thigh.

14, the fourth extender of the thigh or a portion of the *Illiack* muscle.

13, 14, the fifth extender of the thigh called *triceps*.

13, Another part of the fifth muscle.

13, the first bender of the thigh called *Lumbalis*.

13, The 2 bender of the thigh or a tendon of the internall *Iliacke* muscle.

14, the first compasser of the thigh called *obturator externus*.

13, 14, the second compasser of the thigh called *obturator internus*.

13, 14, the second extender of the foote called *Gastrocnemius externus*.

13, the beginning of the two extenders of the foote.

13, their fleshy beginning.

13, Their contiguity or meeting together. 13 the swelling of both the calues. 13, the beginning of the Tendon of these muscles. 13, 14, the backe of the share-bone without flesh. 13, 14, the head of the thigh bone compassed and defended with a membranous Ligament. 13, The place of the thigh bone without flesh. 14, The rumpe bone without flesh. 13, 14, The exterior and greates proesse of the thigh. 14, A rough line of the thigh whereinto is inserted the first muscle of the thigh called *triceps*. 14, The bone of the legge and the outward head of the thigh bored. 14, The tendon of the third extender of the foote. 14, The beginning of the fourth extender of the foote. 14, The insertion of the tendon of the first and second Muscles of the foote. 14, The tendons of the tenth muscle, of the thigh reflected to the haunch bone. 13, the nervous head of the backpart of the first extender of the thigh. 13, The fleshy head of the same Muscle. 13, Carrying the proportion of a mouse. 13, The tendon of the first part inserted into the inner tendon of the thigh. 6, Char. 13, the third part of the fifth Muscle. 7, Char. 14, another part of the fifth muscle. 8, 9, Char. 13, two fleshy portions or the fleshy pouch which adhereth to the second compasser of the thigh. 13, 14, the third extender of the foote called *Plantaris*. 14, 15, the fourth extender of the Foote called *Soleus*. 15, a cavity betwixt the tendon of the forenamed muscle and the other. 15, the place of the bone of the leg without the flesh. 15, the lower abductor of the greates toe. 15, the abductor of the little toe.

TABVLA XXXIV.

low, Figure 2, x a c f, fig. 5, 6, above char. 9, f 13, 14, x] lurketh in the bowle of the hanch-bone, occupyeth the inside of the forenamed perforation, is stronger then the former, and distinguished there-from by a membrane to which it groweth. It ariseth fleshy and broad from the circumference of the perforation on the inside and appeareth notable liuid having three lines, or inscriptions. Afterward it is by degrees contracted or straightned, [table 31, figure 2, a c. unto f] and runneth ouertwart about the coxendix outward, [Table 34, Figure 13, x] and above the cavity which is formed like a pully it hasteneth to the great trochanter where it is reflected; the reflected part being fleshy and that which toucheth the cavity nervous. At this cavity it is increased with three round Tendons [table 34, figure 14, f 14] in the very reflection; which tendons beeing a little separated one from the other doe

doe passe forward, and when they are past the cavity on the backside they are againe collected and make one nervous tendon, [tab. 43, fig. 13. X. 8, 9] which tendon is led ouerthwart and together with the first compasser is inserted into the hinder cavity or sinus of the great *Trochanter* or head of the thigh, and into his roote. And this was Natures counsell determining to adde strength to this muscle; for if it had beene wholly fleshy, in his reflection and motion it would haue beene hurt by the hardnesse of the bone. Wherefore also there groweth to the Sinus a strong membranous ligament which is smooth and lined ouer with a viscid humor for the more easie circumaction of the muscle. But this Sinus hath appearing in it two lines lightly eleuated, which running ouerthwart doe diuide the three forenamed tendons into three cavities; so that in this one cavity euery tendon hath a peculiar Sinus.

And least these tendons should slip out of the cavity of the bone after they are reflected, Nature created a fleshy purse wherein the Tendon of this muscle is placed, which purse resembleth two Muscles, [tab. 38, fig. 16, xx] one vpper and another lower. The vpper [tab. 32, fig. 6, char. 8] as also the lower, [tab. 31, fig. 6, 13, 14, char. 9, fig. 16, x] doe arise fleshy and slender; from the acute proesse of the haunch-bone the vpper, the lower from his appendix and both of them doe accompany the second compasser euen to his insertion and are together inserted into the cavity of the great *Trochanter*.

Their vse is together with the second compasser to helpe the circumaction or compassing of the thigh.

There is also another muscle first described by *Fallopins*, which lyeth vnder the foresayde purse, [tab. 34, fig. 14, *] which ariseth short and very slender from the backe-part of the coxendix and being led about to the outside of the thigh, is with a strong and round tendon inserted into the backside of the great *Trochanter*, or into that space which is betwixt the two *Trochanters* or heads of the thigh. His vse is to leade the thigh in compasse backward. And this muscle haply may be diuided into two.

Arantius alter he hath described this muscle found out by *Fallopins*, hee addeth another, so making the number of the muscles of the thigh to bee a full Iury in these words.

When you haue cut away the muscles which bend the legge from their originals, if you diligently marke the place, you shall finde vnder the eleuenth muscle a twelfth, which is much stronger then the former, but lyeth very deepe. It hath an originall opposite vnto the eleuenth, beginning from the forepart of the share-bone where it is perforated, and it is distinguished with a membrane of the nature of a Ligament. This originall, sayeth hee, is fleshy and almost orbicular or round. It degenerateth into a strong and round tendon. This muscle being ledde about like a semicircular to the outside of the thigh, together wth the second compasser and the purse, that is, with the tenth and eleuenth muscles serue to guide the sphericall or round motion of the thigh.

CHAP. XXXIX.

Of the Muscles of the foote.

THE Foote is mooued two wayes directly and to the sides; directly also or in length two wayes: for it is either extended backward when it is led out of his transuerse position, a little obliquely toward the earth (and that by the helpe of five Muscles placed in the back-part, together with the second and third benders of the toes) as when we walke or dance: or it is bent forward by three muscles, to which may be added that portion of the Muscle which some make the ninth but we account it for part of the second muscle which stretcheth the toes: and these are placed together with the first and second extenders of the toes on the forepart but the outside of the legge, for the inside of the legge euen vnto the Calse is without flesh. This motion is not so strong as the former, and therefore doth not stand in neede of so greate muscles.

The Foote is also mooued to the sides and so a little compassed; which motion because it is very weake, hath not any particular or priuate muscle allotted thereto, but it is ledde to the outside by the anterior Muscles and to the inside by the posterior. The extending Muscles therefore of the foote are five, and the benders three.

The first extender is called *Gastrocnimius internus* [Table 31. and those that follow figure

The purse.

like two muscles.

Their vse.

FIG. XI.

FIG. XII.

minor. p 10, 11, 12, the first muscle of the thigh called *Triceps*. o 10, 11, 12, the sixth muscle of the thigh called *Lumbalis*. o char: 12, the forepart of the fifth muscle of the thigh. r 10, 11, 12, the seventh muscle of the thigh called *Hiacin Internus*. u 10, 11, 12, the eighth muscle of the thigh. o, 12, The first Compasser of the eight called *Obturator externus*. a 10, the second extender of the foote called *Gastrocnimius externus*. A, 11, 12, the holy-bone. H 10, the second extender of the legge called *Vastus externus*. M 10, 12, the second bender of the foote called *Peroneus primus*. N 10, 12, the third bender of the foote called *Peroneus secundus*. O 10, the first extender of the toes called *Pollicis tensor*. T 11, the lower abductor of the great toe. V 10, the abductor of the little toe. X 10, the bone of the leg without flesh, with the ligament which runneth betwixt it and the Brace. Y 10, 11, the vpper abductor of the toes. Z 20, makes the muscles called *Craecus*. z 11, 12, the first muscle of the backe called *Quadratus*.

a 10, the spine of the haunch-bone bared from the muscles.
b 10, the greater exterior proceffe of the thigh.
a b, 12, the originall of the first extender of the thigh at a, his tendon at b.
c 12, the share-bone bared.
f, 12, the thigh-bone without flesh.
g, 12, the backpart of the whirle-bone regarding the ioynt, the tendons grow to the fore side.
b, 12, the tendon of the second extender of the leg called *Vastus externus*.
i 12, the insertion of the fourth bender of the leg called *Biceps*.
k 12, the connexion into one of the tendons of the 7, 8, and 9, muscles.
l 12, the tendon of the ninth muscle of the leg called *Rectus*.
m 12, the forepart of the leg bone without flesh.
u 10, The originall of the second bender of the foote.
n 12, the forepart of the Brace bared.
o 12, A ligament placed betwene the bone of the leg and the brace.
o 10, the outward ankle.
p q 10, the body of the second bender of the foote before and behind.
r 10, the beginning of the tendon of this muscle arising out of the middest of his body.
s 10, the tendons of the third bender of the foote reflected to the outward ankle.
y 10, the originall of the third extender of the legge called *Vastus internus*.
d 10, the fourth bender of the legge called *Biceps*.
o 10, 11, 12, the third extender of the legge called *Vastus internus*.
z 10, the third extender of the thigh called *Gluteus*.

per-

perceiued before Diffecion in those bodies that are musculous or fleshy. This Muscle not farre from his originall is ioyned with the first with fibrous ty es and groweth thereto at the middle of the Leg: [tab. 13, d] and therefore *Sylvius* and *Laurentius* call them *Gemelli* or the *Twins*. This muscle when it hath formed the ourward part of the calfe endeth in a tendon which is so mixed with a Tendon of the former that it seemeth to bee but one Muscle to *Columbus* and *Archangelus*, for they haue but one tendon and one implantation, and these two together with the fourth doe make the pulpamentum, the pulpe or calfe of the Legge. But because in the direction of the Legge those heades are returned backward and so compressed; least any offence should thereby proceede, each originall hath a small sidebone ioyned to it to receiue the violence and abate it in their smooth and slippery Surface which standeth vp from the substance of the Muscles, and doeth regard the smooth superficies of the heades of the thigh whereupon they leane. These Side-bones also doe keepe the Muscles from attrition and laceration and adde strength vnto them.

The side bones.

The third Extender is called *Plantaris* or the Muscle of the palme or treade [table 13, and those that follow, fig. 7, 14, 16, H] It lurketh in the hamme vnder the former and is very slender. It ariseth with a fleshy and narrow originall from the outward head of the thigh neare the ioynt, but descending obliquely from the externall toward the internall part it is dilated: yet the fleshy part thereof is small, for presently vnder the knee it determineth into a very slender neruous and exceeding long tendon [tab. 14, 15, 16, p Tab. 31, fig. 2, and 4, H] so long that among all the round Tendons of the body there is none longer. This tendon is spread ouer the Muscle following, whereto in his progresse it is strongly tyed and implanted into the inside of the heele behinde. Sometimes it groweth broade and by the sides of the heele is spent into the whole skinne of the palme or plant of the foote, as the palme muscle in the hand. But when this Muscle (as it is with the muscle of the palme of the hand) is wanting, then his tendon is substituted by the second bender of the toes. His vse is to writhe and turne the foote inward.

The 3. extender.

The fourth Extender is called *Soleus* or the Muscle of the Soale. [Tab. 31, and those that follow, fig. 2, 7, 14, 16, I] It is the greatest and the thickest Muscle of the foote and lyeth vnder the former Muscles, and where the two first leane vpon it, it is liuid like them. It ariseth neruous and stronge from the backpart of the *Fibula* or Brace, where it is articulated with the *Tibia* or Leg-bone, and becomming thicker it exceedeth in bredth both the bones of the Leg, but about the middle it is by degrees angustated or straytned, and a little aboue the heele degenerateth into a thicke and very strong Tendon, which on the foreside is nourished or encreased with a substance like flesh farther then it is on the backside, and being vnited with the tendon of the first and second Muscles [tab. 38, fig. 16, p 1] is implanted very strongly into the backpart of the heele, where for this Muscles sake it is depressed and rough. His vse is to extend the foote and firme it vpon the ground.

The 4. extender.

But because the bone of the heele standeth out beyond the rectitude of the bone of the Leg, this Tendon a little before his insertion departeth from the Legge [fig. 15, *] and maketh an empty cavity, through which the Butchers peirce their Cammockes to hang the beast vpon in the shambles; for in the whole body there is no Tendon stronger then it. *Hippocrates* called it *Chorda*, where hee saith that vpon the fracture of the heele there follow dangerous Feuers full of Hiccocks and convulsions.

The fift & last Extender is called *Tibialis posticus*, the hinder Leg-muscle. [tab. 31, fig. 2, 7, 18, 19, K.] It lyeth next to the bone betwixt the Brace & the Legge vnder two Muscles which bend the Toes. It ariseth from the two foresaid bones [Fig. 18, L] and presently becommeth fleshy and broade, descending fleshy vnto the extreame appendix of the Legge, vpon which bone for the most part it lyeth through his length: it cleaueth also to a Ligament which lyeth betwixt these two bones, from whence haply his originall gathereth strength, and in the middle of the Leg-bone from the inside onely it produceth a round neruous, and strong Tendon which tooke his beginning a little within the substance of the Muscle. This tendon creepeth through a cavity grauen in the Leg-bone neare the inner ankle vnder the transuerse Ligament; and obliquely attayneth vnto the soale of the Foote vnder the Muscles which occupy the plant [tab. 36, Fig. 18, 19, m] or Treade, and is strongly inserted into the proceffe which is on the lower side of the bone of the *Tarsus* or After-wrist of the foote which is neare the Cube-bone, which proceffe was onely created for his insertion. His vse is to draw the foote inward, it helpeth also the motions of the first, second and fourth Muscles, and therefore moueth the foote to the earth, and sometimes leadeth it backward, when we would stand vpon our tip-toes as we say. And thus much concerning the extending

The 5. extender.

tending Muscles of the foote on the backpart thereof. It followeth that wee should intreat of his bending or *anterior* Muscles which we sayd are three.

The 1. bender.

The first Bender is called *Tibialis anticus*, the forward Leg-muscle, [tab. 31, and those that follow, Fig. 1, 7, 8, L] because it cleaueth to the forepart of the Leg-bone at his outside.

It is the larger of the Benders and very nearly resembleth a Snake and lyeth vpon the Muscles of the Toes. It ariseth acute or sharpe neare to the *Brace* where it is articulated with the Leg-bone. Presently it is dilated, and on the inside of the Leg-bone it is ioyned to an acute line and becomming streighter by degrees vnto the middle of the Leg-bone determineth farre aboue the foote into a round, neruous and strong tendon, [Fig. 2. and 18. n] which tendon also sometimes riseth vp vnder the skinne, and growing from the lower appendix of the leg and the brace vnder the transuerse Ligament attaineth to the inside of the foote, and conuayed in a reasonable open cauity aboue the vpper part of the After-wrist or the *Tarsus*, is wholly inserted into the inner proceffe of the bone of the wrist of the foote which sustayneth the great toe. His vse is to bend the foote it selfe, and to draw it forward and vpward. This Muscle as also that that went before, especially in that part where they are reflected vnder the wrist and After-wrist of the foote, haue a gristle and feede-bone allowed them by Nature to prevent their attrition.

The 2. bender.

The second bender called *Peroneus primus*, or the *first brace muscle*, [tab. 31, and those that follow Fig. 1, 3, 8, 9, 10, 12, 16, 18, 19, M] is in his whole progresse ioyned with the outside of the precedent muscle, and by it selfe is repressed in the outside of the Leg. It ariseth fleshy and neruous [Figure 10, n.] from the vpper and outward part of the appendix of the *fibula* or *brace*, and becomming fleshy it paceth along the same, cleauing som epart to his side: departing from the *brace* it is on the outside liuid, but on the inside fleshy and ruddy, and being conuayed a little below the middle of the *brace* between two fleshy sides [Figure 10, p, q] out of the very middle of his body produceth an exceeding strong tendon [Fig. 10, r] which is increased in the inside on either hand with flesh, which tendon becomming by degrees without flesh and reflected obliquely toward the backside of the appendix of the brace, and leauing the outward ankle naked [Fig. 10, o] being inuolued in a transuerse Ligament which proceedeth from the brace into the heele and the bone called the *cockall* or the *talus*, it passeth the fissure of the same outward ankle, and being very much reflected vnder the *plant* [tab. 36, fig. 19, t u] is inserted brode into the roote of that bone of the wrist of the foote which lyeth vnder the great toe. I say into the proceffe which is on the outside of that bone: sometime into that bone vpon which the middle toe resteth.

His vse is to leade and bend the foote vpward and outward. But this Tendon passeth in the middest betwixt the bones and the Muscles of the plant or soale of the foote [figure 19, t u] least if it should walke onely vnder the skinne when it is contracted vpward it might compresse the Muscles seated in the soale and hinder their functions. So also in the lower part of the *cake-bone*, there is a cauity somewhat brode but not deepe, smeared ouer with a viscid humor and compassed with a slippery Ligament, at which the tendon is compassed not round lest it should fall thereout, but dilated [table 36, figure 19, t] that so it might more firmly be reuolued at the shallow cauity. Againe the Tendon in the same place is so hardened that it is like a grystle, yea sometime so bony as if it were a feede-bone, that it might better and more readily auoyde the violence of the bending or flexion at an acute angle.

The third.

The third and last bender called *Peroneus secundus*, the second *brace muscle*, [Table 31, and those that follow figure 3, 8, 9, 10, 18, 19, N] is hid vnder the former (his tendon excepted) and is like thereto. It ariseth also with a long originall from the same appendix of the brace, and being fleshy descendeth downe the same brace to which it is tyed, and when it hath ouercome the middest thereof, it departeth into a round Tendon which is reflected toward the backside of the brace and is fastened to the foreside of the Tendon of the second bender, and lying vpon a cauity ingrauen in the backside of the appendix of the brace and compassed with the transuerse Ligament it descendeth forward: but at the vtter and lower part of the ankle it is againe reflected, diuided, and becommeth forked, [tab. 35, figure, 10, f] lest it should bunch vp too high, and is implanted [table. 36, figure 19, x] very strongly with a double and broade insertion into the proceffe of that bone of the wrist of the foote which sustains the little toe. His vse is to leade and bend the foote outward.

To

To these eight Muscles of the foote *Vesalins* and *Falopius* add a ninth [tab. 33, fig. 8, 9, p] which *Banishine* taketh rather to be a part of the second extender of the toes [tab. 33, fig. 7, 8, 9, p] then a particular muscle of it selfe. And thus much of the muscles of the foote.

Falopius: ninth muscle.

CHAP. XL.

Of the Muscles of the Toes.

He foure toes of the foote are mooued almost with the same motions that the fingers of the hands are mooued with. But the great or thumbe-toe is not led after the same manner with the thumbe of the hand, that is, with a flexion opposite to the other fingers, but his first ioynt is bent after the same manner with the first ioynts of the rest of the toes, because his position is in the same order. The toes therefore are mooued directly or sidelong. If directly, then eyther they are bent toward the earth, euery ioynt being mooued apart, and that either directly onely, as the second and third ioynts of the foure toes, and the second of the thumbe or great toe; or directly and obliquely together, as the first ioynts of all the five toes. If they be extended, the extension is made directly or in a right line, and so all the ioynts are mooued together. If they moue to one side that motion is eyther outward, as when the foure greater are led to the little toe, and the little toe led from the rest: or inward when the thumbe-toe is ledde from the rest and the foure lesser toes mooued toward it. All these motions are absolued by three and twenty muscles, whereof some are seated in the leg, that is to say, part in his fore part and part in his back part. Others are placed in the foote it selfe, properly so called.

The motion of the toes.

Their muscles 23.

The first Muscle of the toes is called *Pollicis tensor*, the extender of the great toe or the first extender, [tab. 33, fig. 8, 9, p] it is seated in the fore side of the legge, together with that which next followeth at whose inner side it lyeth.

First.

It ariseth fleshy from the outside of the legge where the bone of the leg or the *Tibia* departeth from the *Brace* or the *Fibula*. After it descendeth and groweth in his whole passage to a membranous Ligament which commeth betwixt the leg and the *Brace* bones and so attaineth vnto the fore side of the leg; thence creeping vnder the transuerse Ligament [tab. 31, fig. 1, char. 2] and ouer the foote, it is inserted into the vpper part of the whole length of the great toe to extend it. Sometimes the tendon is diuided into two, one of which is inserted into the last ioynt of the great toe, the other into the wrist of the foote to bend it. And this latter tendon in some bodies seemeth to be a distinct muscle. But that saith *Columbus* is very rare.

The second extender [tab. 31, and those that follow fig. 1, 3, 7, 8, 9, p] is placed in the fore part of the leg, but lurketh vnder the first muscle of the foote. It ariseth with an acute and neruous originall [tab. 33, fig. 8, char. 10] which presently becommeth fleshy, from the top or extremity of the appendix of the leg, where vnder the knee it is fastened to the *Brace*; thence it descendeth directly along the *Brace* and about the middle thereof it casteth off from his outside a fleshy portion, [tab. 31, and those that follow fig. 8, 9, p] which portion descending downward, maketh that muscle which *Falopius* calleth the ninth Muscle of the foote: presently falling yet lower vnder the transuerse Ligament which is on the fore side of the leg, [tab. 31, fig. 1, char. 2] to which it adhereth; at the end of the *Fibula* or *Brace* it degenerateth into a tendon, [tab. 33, fig. 8, char. 12] which tendon before it passe the transuerse Ligament is diuided into foure round tendons separated and conueyed through the backe of the soale vnto the foure toes, (beside the great toe) which run through their whole length, and becomming broader are inserted into their vpper parts. Their vse is to extend the three ioynts of the foure toes together.

Second.

Fleshy parts.

The third muscle of the toes is called *Pollicis Flexor*, the bender of the great toe, or the first bender, [tab. 31, and those that follow, fig. 2, 7, 16, 17, 2,] and is seated with that which next followeth in the backpart of the leg vnder the muscles, which make the *Palp* or *Calf*, and it is almost altogether fleshy.

Third.

It ariseth [figure 16, character 13,] from the backe-part at the connexion or coniunction of the *Brace* with the Legge-bone, where from his inside there issueth a round Tendon, [Figure 16, 17, character 14,] which may bee scene manifestly to haue his

originall out of the flesh, [Table 36. figure 16, a] which tendon passeth obliquely vnder the Ankle at the inside of the heele, where a cavity is engrauen for it, and where also it is couered with a transuerse Ligament: thence it inclineth vnder the plant or treade of the foot, at which place sometimes it transmitteth certaine small portions into the tendons of the third muscle with which it is commixed, [fig. 16, char. 19] and when his especiall tendon is receiued by the transuerse Ligament, it is inserted with a broade implantation into the second bone of the great toe after it hath passed the length of the first, which second bone it bendeth. Sometime vnder the soale it is diuided into two tendons the largest whereof it transmitteth to the great toe, the lesser vnto the next, and then the second bender is diuided onely into three tendons and no more. This tendon before it is inserted into the second bone of the great toe hath a great seede-bone set before it with a slippery and smooth surface.

The fourth.

The fourth Muscle of the Toes or the second Bender which is called *Digitum flexor magnus*, the greates Bender of the Toes [tab. 36. fig. 16, 17, 18, R] lyeth neare the former and lea- neth rather vnder the Legge then vpon the Brace-bone [tab. 36. fig. 18, rather A, then B.]

It ariseth fleshy from the Leg-bone vnder the hamme [fig. 19, char. 8] and descending almost to the heele, it produceth from the inside a round tendon [fig. 16, char. 7] which passing along vnder the inner ankle, and in a peculiar cavity of the heele [fig. 19, D] and vnder the transuerse Ligament which groweth from the appendix of the Legge, it runneth vnder the tendon of the third Muscle in the soale of the Foote with which it maketh a decussation [fig. 17, betwixt the 17, and the 15, characters] and in the middle of the foot is deu- ided into foure tendons, [fig. 17, char. 18] which being bound with Ligaments and passing through the Section or diuision of the Tendons of the subsequent muscle are inserted broad according to the length of the bone into the third ioynt of the foure Toes. The vse of this Muscle is to bend those foure toes, to contract them strongly and to leade them one to ano- ther.

The fift.

The fift Muscle is also the third bender. [tab. 36. fig. 16, 17, S] It is seated vnder the mid- dle of the soale and ariseth with an originall mixed betwixt a neruous and a fleshy from the lower part of the heele-bone, and the forepart of his protuberation. Presently after his originall it becommeth fleshy and passeth toward the Toes, being by degrees dilated or spread abroad according to the forme of the foote. At the middest whereof it is deu- ided into foure fleshy parts; [tab. 36. fig. 16, char. 21] which parts being separated doe each of them produce a round tendon which are receiued at the roote of the first ioynt by the trans- uerse Ligament, and being deu- ided (as it is in the hand) with a long section each of them growing broad, are inserted into the second bone of the foure Toes.

The vse of this Muscle is to bend the second ioynt of the foure Toes. There also grow- eth very strongly a broade tendon [tab. 34. fig. 15, 2] vnder all the fleshy substance of this Muscle, which serueth instead of a broad tendon of the hand, and sometimes is the tendon of the third Muscle of the Foote which is called *Plantaris*. This tendon is of exquisite sense the better to forewarne vs vpon the inst of externall iniuries.

[Table 36. is the same with 31.]

The sixt.

The sixt Muscle is called *Abductor pollicis inferior*, the lower backe-leader of the great Toe. [tab. 31, and those that follow, 1, 2, 7, 11, 16 g] It lyeth on the inside of the Foote throughout the length thereof, and resembleth the fashion of a Mouse. His originall is neruous from the heele on the inside neare the muscle foregoing, and becomming fleshy it is fastned to that bone of the wrist of the Foote which supporteth the great Toe, and degenerateth into a round tendon which is implanted on the outside into the first bone of the said great Toe to leade it from the rest.

The seauenth.

The seauenth Muscle is called *Abductor minimi digiti inferior*, the lower backe-leader of the Little Toe. [tab. 31, and those that follow, fig. 3, 4, 15, 16, V] It is situated in the exter- nall part of the Foote and ariseth with a neruous originall from the vter part of the Heele where there is a protuberation, and becomming fleshy it expresseth the forme of a perfect Muscle, and is affixed to that proceffe of the wrist-bone which sustaineth the little Toe, and determineth into a round Tendon which is infixed into the outside of the first bone of the little Toe to leade it from the rest.

These three are couered or inuested by a thicke and broade tendon as it was in the palme of the hand.

The 8, 9, 10, and 11.

The 8, 9, 10, and 11. Muscles, or the 3, 4, 5, and 6. Extenders, called also *Lumbricales*, the

Table 38. sheweth the Muscles of the Foote, and the Toes thereof. But the 18. and 19. Figures shew the right Foote as did those two in the 34. Table, but here it is more bared from the Muscles.

TABVLA XXXVIII.

a 16, The backe of the hanch bone bare.

b 16, A membranous ligament occupi-
ing the greate perforation of the share-
bone.

m 18, The beginning of the fift exten-
der of the Foote at *l*, his tendon at *m*
18, and 19.

n 18, A portion of the Tendon of the first
bender of the foote.

p 16 The tendon of the 3. muscle exten-
ding the foote.

r 19, the 2. bender of the foote or the
first *Peroneus* reflected in the foote.

xx 16, two fleshy partes compassing
the Tendons of the tenth muscle of
the thigh.

x 19, The insertion of the 3. bender of
the foote.

A 18, 19, The bone of the leg.

B 18, 19, the *Brace*.

CD 18, the bosome or cavity of the ten-
dons of the 2. and 3. muscles of the
toes.

E 18, Small bones neare the first ioynt of
the greate toe.

F 19, a ligament going betwixt the bones
of the leg and *Brace*.

H 16, the 3. extender of the Foote.
called *Plantaris*.

I 16, the 4. extender of the foote called *Soleus*. *K* 18, 19, the first extender of the foote called *Tibialis posterior*. *M* 16, 18, 19, the second bender of the foote or the first *Peroneus*. *N* 18, 19, the 3. bender of the foote or the second *Peroneus*. *Q* 16, 17, 18, the first muscle bending the toes of the foote or the bender of the great toe. *R* 16, 17, the second bender of the toes or their greate bender. *S* 16, 17, the 3. muscle bending the toes or their other bender. *T* 16, the lower *Abductor* of the greate toe. *V* 16, the *Abductor* of the little toe. *X* 17, 18, the foure muscles called *Lumbricales*. *Z* 16, the muscles called *Interossei* or the bone bound muscles. *a* 16, the muscle mouing the Leg obliquely called *Popliteus*. *o* 16, the first bender of the thigh called *Lumbalis descendens*. *r* 16, the 2. bender of the thigh called *Iliacus internus*. *s* 16, a por-
tion of the first compasser of the thigh. *4* 16, the first extender of the foote called *Gastrocnimius internus*. *o* 16, the second extender of the foote called *Gastrocnimius externus*. ** 16*, the thigh bone bare. 1, 2, 3, Char. 19, three *Sinus* or bosomes made to carry three tendons. 3, char. 16, a ligament hanging from the ioynts of the Toes, doing the office of the broad tendon. 4, 5, Char. 16, the originall of the muscle of the ham called *Popliteus* at 4, his insertion at 5. 13, char. 16, the originall of the first bender of the toes. 14, 15, Char. 16, 17, the tendon of that muscle at 14, his insertion at the greate Toe 15. 16, char. 16, the be-
ginning of the second bender of the toes. 17, char. 16, 17, the tendon of the same arising there. 18, char. 17, the tendon diuided into foure parts. 19, char. 18, the commixtion of the tendons. 20, 21, Char. 16, the third bender of the toes, his originall from the heele at 20, his diuision into foure tendons at 21, 22, char. 16, 17, 18, a fleshy portion growing to the bones of the foote at the great toe.

Figure 20. sheweth the Ligaments growing to the ioynts and the Bones of the Leg & the Thigh.

AB, The thigh bone at *A* his vpper head at *B*. *CD*, the 2 lower heads thereof. *E*, the bone of the Legge. *F*, his vpper protuberation, *G*, the lower *Sinus* or cavity. *H*, the inner ankle. *I*, the *Brace-bone* called *Fibula*. *K*, the vpper ankle. *L*, the vpper, a round ligament of the head of the thigh. *L*, the lower a muscle in the calfe or the fourth of the Foote. *MM*, a ligament compassing the vpper ioynt of the thigh. *N*, A ligament growing to the greater proceffe of the thigh. *O*, A Ligament affixed to the lesser proceffe of the thigh. *PP*, a ligament inuoluing the ioynts of the knee. *QR*, a ligament set to the vtter and inner side of the knee. *S*, a ligament coupling the protuberation of the leg-bone marked with *F* and the thigh together. *TV*, a ligament binding the leg-bone and the *Brace* together above and below. *X*, a membranous ligament fastening together the Legge and the *Brace*. *YZ*, a transuerse ligament gathering the nerues. *a* a tendon made of three muscles of the foote and inserted into the heele. *ab*, liga-
ments ioyning the heele to the Leg and the *Brace*: from the bone of the leg to the heele at *a*, from the *Brace* to the heele at *b*. *cd*, A gristly Ligament running from the inner Ankle into the inside of the *Talus* at *c*: another ioyning the *Brace* to the *Talus*.

the wormy Muscle [tab. 36. fig. 17. 18. x] are seated vnder the soale of the Foote, and arising from the Ligament which compasseth the foure tendons of the perforating Muscle or the second Bender, are implanted round and small into the Tendons of the Muscles extending the Toes, to extend or stretch forth their second or third ioynts. These muscles for their farther strength receiue a fleshy portion from the heele, which lyeth vnder the three forenamed Muscles.

The twelfth.

The twelfth Muscle called *Abductor digitorum superior*, the vpper backe-leader of the toes, [tab. 31. fig. 1. 8. 9. 10. 11. T T] is seated in the vpper and gibbous part of the Foote. It is a broad and slender Muscle, and ariseth fleshy from the Ligaments which are at the heele & the bone called *Cubiforme* or the Dye aboue the wrist and after-wrist of the Foote, and running obliquely toward the toes is diuided into foure fleshy parts euery one of which make a round tendon. The greatest of which is inserted into the vtter side of the great toe toward the height thereof. The second of the next toe. The third of the middle toe, and the fourth of the fourth toe. Sometimes also but rarely a small part is lent vnto the little toe.

The vse of this muscle is to moue the toes to the sides and to leade them backward and outward. But when it hath onely foure tendons, then the tendon belonging to the little toe ariseth from the third externall muscle of the foote although the lower backe-leader of the little toe or the seauenth Muscle will serue that turne.

The thirteenth.

The thirteenth Muscle ariseth with a broad and neruous originall from the ligament of the first ioynt of the little toe, sometime of the toe next it, afterward becomming fleshy, it passeth athwart ouer the first ioynt of the toes and determineth in a broad but short tendon which is inserted a little inward into the first ioynt of the great toe.

The vse of this muscle is double, first that when it worketh wee may better hold our feete as wee say, in vnequall places, for it maketh a kinde of apprehension. The second that when it worketh not, it might serue the foote in stead of a Ligament, least when we walke vpon the euen ground, the soale of the foote should be enlarged beyond that that is fit, and so the toes led one from another. Concerning this Muscle saith *Bauhine*, *Iulius Casserius* first writ vnto me.

Casserius.

The ten muscles betwixt the bones.

Vnder this muscle lye the tenne muscles called *Interossei* or the *bone-bound* muscles (for you must giue vs leaue to make english words as our Authors haue done in Greeke and latine) [tab. 36. 18. 19. z] which are to be referred to the benders of the toes. These haue their situation in the soale of the foote where they make a rude and indigested lump of flesh diuersified with right fibres, which lump proceedeth from the beginning of the after-wrist, and passing throughout his length fls vp the spaces betweene the bones and are inserted two and two into the rootes of all fise toes, or at the Ligament of the first ioynt toward the inside, that so when two worke together, they may bend the first ioynt, but when one alone worketh it leadeth the same ioynt to the side eyther outward or inward as the site and originall of the muscles is. To the short and broad tendons of these muscles doe grow for their further strength seed-bones, such as are in the hands, but greater.

The conclusion of the muscles.

And thus haue wee brought to an end this crooked and crabbed history of the muscles concerning which I know not whether I should rather craue pardon or pittie; pardon I presume I shall not neede to craue of them that vnderstand through what a labyrinth I haue led my pen: pittie also will do me little good now the paine is past. Acceptance shall be better welcome then eyther, and an ingenuous mind that measureth my foote by his own Last. One other passage remaineth in this Booke, and that is concerning those other kinde of flesh which are found in the body of man, to wit, the flesh of the *viscera* or *Entrals* and that of the *Glandules*, which two when we haue lightly passed ouer, we will proceede vnto the Booke of the Vessels.

CHAP. XLI.

Of the flesh of the Entrals or Bowels.

Parenchyma
what it is.

Alen esteemed the flesh of the Bowels to be similar and simple, not onely in respect of the mition, because all euen their least particles are of one and the like nature, whence some Arabians haue called it *Consusa*. *Erasistratus* called it first of all men *μαρμαρυγμα*, as it were an affusion or concretion of blood. This flesh *Erasistratus* esteemed to haue no other vse but onely to separate the vessels and to serue as

a soft cushion or pillow for them to rest on, and to strengthen and establish their passage, but we esteeme it to be of a great deale more excellent vse, for we thinke that it is the chiefe part of the bowell to which the officiall or common action thereof primarily appertaineth. So Sanguification primarily and of it selfe belongeth to the Flesh of the Liuer; to the veines secundarily onely and by influence.

His excellencie.

The Flesh of the Longues prepareth the ayre for the Heart, the Flesh of the Spleene purgeth the Lees or foeculencie of the blood, the flesh of the kidneies draweth & separateth the whey or vrine. Wherefore this Flesh maketh the proper substance of the bowell or entrall. Onely this amongst all sorts of Flesh is insensible, and according to *Galen's* testimony in *Arte parua* is of the number of those parts which haue their faculties seated and established in them not influent or deriued from other parts.

The Flesh of the Liuer is red and moderately thicke, neither doeth the heate thereof alone further the sanguification of the veines, as the Kell, the Spleene and the parts thereabouts doe assist the concoction of the stomacke: But by an in-bred and proper power it sealeth or imprinteth vpon the blood his stampe or forme, his temper and colour.

Of the Liuer.

The Flesh of the Spleene is a rare spongy or fungous *Parenchyma*, loose like the faster sort of sponges, and fit to draw and receiue muddie and melancholique humors.

Of the spleen.

The Flesh of the Kidnies is red, fast and solid, differing not much from the substance of the Heart, sauing that it is not intertexted or wouen with fibres. It was made solid, least if it had beene loose and flaccid it should not haue beene able to containe the vrine that it receiued. It draweth by an inbred power whey or vrine from the whole body, separateth it being mingled with the blood, and transfuseth it drop by drop into the membranous cauities.

Of the Kidnies.

The Flesh of the Longues is light, rare and like vnto a sponge, made as it were of the froth of the blood congealed together. It is light that it might easily be lifted vp, and fall againe without violence, and so readily obey or follow the motions of the Chest. It is rare and spongy that like a paire of bellows it might presently bee filled with the ayre wee breathe in, as also to make the way fit for the breathing out of sooty and smoaky vapours. This Flesh prepareth for the Heart one of the materials of the vitall spirit, that is ayre, for the outward ayre which hath much impurity mixed therewith, could not at the first hand be made a fit nourishment of the inward spirit, and therefore it was necessary that it should be altered by little and little, and by some stay made in the Lungs, acquire or attaine a quality familiar to the inbred spirit.

Of the Lungs.

Concerning the flesh of the Heart, it may be doubted whether it ought to be referred to the flesh of the bowels or to the flesh of the Muscles: *Galen* holdeth on neither side; for a *Parenchyma* hath no fibres, the Heart is wouen with them after a strange and admirable manner. Againe, the motions of the Muscles are Voluntary, so is not the motion of the Heart. The Flesh therefore of the Heart is peculiar to it selfe alone, such as you cannot finde in the whole body againe.

Of the heart.

There is no lesse scruple also concerning the Flesh of the Tongue, for it is as nimble as an Eele; turning it selfe into a thousand motions, yet are there no fibres running there-through, and therefore the flesh thereof cannot bee sayde to bee musculous, rather (if all things be considered) it inclineth to the nature of a *Parenchyma*. And so much shall bee sufficient to haue said concerning the Flesh of the Bowels or Entrals.

CHAP. XLII.

What a Glandule is, and how many kinds there be of them.

BEcause many of the Ancients haue defined a Glandule to be a *Flesh rowled vp into it selfe*: I haue thought fit sayth *Laurentius* for order sake to refer the whole kind or kin of Glandules vnto Flesh.

A Glandule therefore which the Græcians call *αδνη*, is a simple part, rare and fryable, soft like a sponge, appoynted by Nature to firme and establish the vesselles, to sucke or drink vp superfluous humors, & to water or dew some parts that stood need of moisture.

What a glandule is.

The Authour of the Booke *de Glandulis*, whether it were *Hippocrates* or *Polybius*, hath elegantly exprest the nature of a Glandule, where hee sayeth, *Their Nature is spongy for they are rare and fat*. That they are of such a nature you shall easily finde if you presse them hard

hard betwixt your Fingers, for they will yeeld an oylie humour and blood, white like phlegme. Now it is consonant to reason that they haue such a substance, not for nought, but for some particular and especiall vse. That vse is three-fold.

The first vse
of glandules,

The first vse of Glandules is to firme or establish the diuarcations or diuisions of the vessels. For it was to be feared least the vessels running through large and ample cavities, if they had no other muniment or defence sauing their owne membranes, would in violent motions be broken off, as in great windes boughes are torne from a tree; vnlesse these glandulous bodies did lye soft vnder them and establish & sustaine them. And therefore where the vessels are forcked or deuided, there Nature hath euer placed Glandules vnder them.

So in the diuision of the Gate-veine there is a notable Glandule called *Pancreas* or the Sweete-bread. In the diuarcations of the veines of the Mesentery there are Glandules almost infinite. In the distribution of the ascending trunk of the hollow veine is the Glandule called *Thymus*, which is the sweetebread in calues. In the vessels of the braine the Glandule called *Conarium* or the pine-glandule. In the necke, in the arme pits and in the groynes where the *Iugular axillary* and *crurall* veines are divided, there are Glandules placed to support their diuisions. Wherefore they were made soft and rare, that neither their hardnesse might offend the vessels, and by yeelding they might giue way to their distentions when they strut with blood.

The second
vse,

The second vse of the Glandules is like sponges to sucke and drinke vp fleame, whey and other superuacuous humours, that they should not rush vpon the more noble parts. In which respect their forme is round, somewhat long, and their substance rare and open; so fitted to receiue the greater quantity of any kinde of influxion. This vse the Author of the booke *de glandulis* openeth vnto vs in these words. They beare away the redundancie or surplussage of the rest of the body, and that indeede is their familiar Aliment. It may also by reason be demonstrated that they were ordained by nature to purge away moyst superfluities; for those parts that are hollow, and especially if they be moyst and full of blood, haue more and larger Glandules than those that are solide and lesse succulent, as are the ioynts. So behind the eares about the necke where the iugular veines run, about the arme-pit where the axillary branch is, and about the groynes where the crurall veine appeareth, there are notable Glandules which receiue the superfluities of the principall parts, the Brayne, the Heart and the Liuer, which Glandules are commonly called *Emunctories*, and if they swell or be otherwise affected, they betoken the distemper of their owne bowell or some ill disposition therein. *Hippocrates* in the second section of his 6. booke *Epidemion*, saith *Abcesses* or *Apossemes* (as for example the tumors of the Glandules) are produced as fruitlesse water-shoores of those places, out of which they grow. They also bewray the condition of other places and parts, and especially of the bowels. *Galen* also in the thirteenth booke of his *Methode* saith, that when an Apostematation ariseth neere any notable artery or veine, suddainly do spring vp *Bubones*, that is, inflammations of the Glandules.

The third vse.

Thirdly we adde in the definition, that the vse of the Glandules was to irrigate or water some parts lest they should too easily bee exiccated and dried or made vnfit for motion. Such are some of the Glandules of the Mesentery, which with their moysture doe dew the guts. Such are also the Glandules of the Throttle or the Tongue, which ingender or gather spittle. The Glandules in the corners of the Eyes do make much toward their celerity and ease their motions, and finally those prostrate glandules in the necke of the bladder doe water and moisten the Vreter with an oylie humidity, lest it should be offended by the Acrimony of the vrine. And this is the nature of Glandules properly so called:

Glandulous
bodies,

There is also another kinde of Glandules which may more truly bee called *Glandulous bodies*. Their substance indeede is like vnto a glandule, that is, rare and lax, but it is ordained by Nature for the generation of humours or iuyces which are profitable for the creature. Proper or simple glandules haue neither peculiar veines, nor arteries, nor nerues. And according to *Galen*, they are in the list of those parts which haue faculties inbred and seated in them, not flowing from elsewhere: but these glandulous bodies haue manifest and conspicuous vessels, and are also of exquisite sense. The former haue onely an vse in the body: these latter haue not onely an vse, but do also performe an action. So in *Galen* the Testicles are called glandulous bodies: for their substance is soft and hollow, in which the seede is boyled and perfected. So the dugs are glandulous bodies and haue a power or faculty in them for the generation of milke. Notwithstanding these glandulous bodies doe sometimes afford the same vse that the other glandules doe, that is, to sucke or sup vp the re-

crements

crements or excrements of the whole body: for Nature doth often abuse one and the same part to diuers vses. So *Hippocrates* reckoneth the Kidneyes in the number of the glandules, yea and the braine it selfe is like vnto a Glandule, for it is white and friable, and performeth the offices of a Glandule to the head.

CHAP. XLIII.

A brieue enumeration of the Glandules in the whole body.

HE number of the Glandules is almost infinite, we willl onely runne over the most notable, and of them giue you but a light view, because you haue heard their particular descriptions in their proper places.

In the braine there are 2 Glandules, not very great indeede but very notable.

The glandules
in the braine.

The first is of a turbinated figure commonly compared to a pine-kernell, and called *Conarium*; of which you shall reade in the twelfth chapter of our seuenth booke. It is thought to be ordained for an establishment vnto the veines and arteries which are disperfed into the braine, and maketh the way open for the Animall spirit out of the third into the fourth ventricle. The other is called *Glands Pituitaria*, the phlegmaticke Glandule; of which you shall reade in the thirteenth chapter of our seuenth booke. His porous or open flesh like a sponge receiue the superfluities of the vpper ventricles of the braine, and distilleth them into the Pallate through the holes of the wedgebone. Vnder the eares and behinde them there are many glandules called *Parotides*, appointed to establish the diuisions of the vessels, and to drinke vp the humors of the braine, whose Emunctories they are commonly stiled. Betwixt the skinn and the fleshy membrane of the Face there are many Glandules, saith *Platerus*, which they call *Animelles*, as also betwixt the lower side of the puffed of the cheek, and the beginning of the necke, where the Kings euill doth often arise.

Parotides.

In the inside of the chops which from the narrowness is called *Isthmus*, there do appeare two glandules like blanched Almonds, and therefore they are called the Almonds of the throate and Tonsillæ, and these doe perpetually moysten the chops, the mouth, and the tongue with spittle. There are also two at the roote of the Larynx or throtle, and two vnder the gullet, which oftentimes doe so swell that they interclude the way both of meate and drinke: but of drinke especially, for the solid meate makes it selfe a way by compression, whereas that which is liquid doth rather fill the fungous substance of the Glandule.

The glandules
of the Larynx.

Vnder the top of the breast-bone, in the very diuision of the ascending truncke of the hollow veine there is a glandule called *Thymus* a lecker or sweete-bit for nice pallats, made to establish the vessels.

Thymus.

There are also many others in the cavity of the chest, in the arme-pits, in the groynes, in the armes and in the legs. All which want proper names.

Vnder the Stomacke and the Gut called *Duodenum*, there is a glandulous body, which because it resembleth a simple flesh, they call *Pancreas*, whose vse is to sustaine, imbrace and comprehend the branches of the Gate-veine, which are to be distributed into the stomacke, the gut *Duodenum* and the Spleene, which are onele supported by the lower membrane of the Kell.

Pancreas.

In the Mesentery there are many Glandules, as well to distinguish the vessels as to keepe them from compression, when the guts are ouer-filled or when the *Abdomen* is too much strained, for otherwise the transcolation of the chylus would be hindered. These Glandules also do moysten the guts, and tye as it were the vessels together that in violent motions they might not be broken. In the necke of the bladder neare the sphincter muscle are those glandules which are called *Prostata*, of whose vse we haue spoken partly in the fourth booke, and partly in the former chapter.

The Glandulous bodies we need not in this place so much as to rehearse, for their descriptions are large enough in their proper places; whereto we referre the Reader, and here put an end to our booke of Flesh: and proceede vnto the vessels.

The end of the tenth booke.

THE ELEVENTH BOOK, Of the Vessels, vvhich hath three parts:

The first of the Veines.

The second of the Arteries.

The third of the Sinewes.

The Præface.

In the Heavens the Angels are the Messengers of God, carrying downe his commandements vnto men whome also they guard and defend; so in this *Microcosme* the dull Flesh being of too slow a kind to ensue the noble motions of the Soule, which with his counterpoise it ofmer doth oppresse, our wise Creator ordained spirites of a middle Nature betweene the Soule and the Body, which like quicke Postes, like Pursuants or Heralds might trauell betweene them, and communicate their commission to the particular partes which they receiue eyther at the first hand from the Soule it selfe in the Brayne, or haue it sealed in the Heart or the Liuer, as in her subordinate Officers.

These Spirites *Hippocrates* calleth *Impetuous* bodies, because their motion is sudden and momentanie like the lightning, which in the twinkling of an eye shooteth through the whole cope of Heauen; yea so much more subtile are they then the Lightning, as that the one is visible the other inuisible: or they are like the winde which whiskes about in euery corner and turnes the heauy saile of a Wind-mill, yet can wee not see that which transports it. How necessary therefore was it that such subtile and vndertaking or active Creatures should be confined as well to guide their motion which otherwise would bee inordinate, as also to keepe them from exhaling or vanishing away. Nature therefore because the Spirites are of three sorts, Naturall, Vitall and Animall, hath prepared three kindes of Vesselles for their transportation, Veines, Arteries and Sinewes. The Veines because their guest is not so subtile but a more cloudy and thicke spirit, generated immediately out of the purer substance of the blood, haue but a single coate, as being sufficient to containe a more quiet spirit. The Arteries because their spirits are more sprightfull and impetuous, moouing alwayes with a subsultation, and perpetually playing vp & down, are made (as some thinke) sixefould as thicke as the Veines, the safer to immure the vnruely Inmate. The Nerues are nothing else but productions of the marrowy and slimy substance of the Brayne, through which the Animall spirits do rather Beame then are transported, inuested with the two Membranes wherein the Braine it selfe is inuested, commonly called the *Pia* and *Dura mater*. And this substance was indeede more fit for Irradiation then a conspicuous or open cavity, which would haue made our motions and Sensations more sudden, commotiue, violent and disturbed, whereas now the members receiuing a gentle and successiue illumination are better commaunded by our Will and moderated by our Reason.

The Natures of these three kindes of Spirites wee haue partly handled before in the third, the sixt and the seauenth Bookes: and therefore wee will no longer detain the Reader by way of Introduction, but descend vnto the particular Histories of their Vesselles.

CHAP.

CHAP. I.

What a Veine is.

Having wrought our way through the darke and shady groue of the Muscles *Nulli penetrabilis astro*, into the secret whereof I thinke no wit of man is able to reach: (And therefore it shall be no wonder if we bring some scratches out of so thorny a copse) we are now arrived in these medowes, where the vessels like so many brookes do water and refresh this pleasant Paradise or modell of heaven and earth; I meane the body of man. And surely by these streames doe grow many pleasant flowers of learning to entertaine and delight our mindes beside the maine profit arising there-from vnto the perfection of that Art we have in hand.

Vnder the name of vessels we vnderstand three kinds, Veines, Arteries and Sinewes, because out of these as out of riuers, doe flow into all the parts of the body Blood, Heate, Spirits, Life, Motion and Sense. Three kinds of vessels.

Wherefore *Hippocrates* is his Booke *de Corde* called them; *ποταμοὶ φύσας ἀνθρώπων*, the riuers of the body of man. Neither let any man taxe vs for inuerting our order when wee first begin with the history of the Veines, then descend vnto the Arteries, and lastly vnto the Nerues; because the Veines, are most simple as hauing but one proper coate and that thin; the Arteries, two and those thicker; but the substance of Nerues is manifold, as being within soft and marrowy, without membranous. For they must remember that the maine guide of our labour is the order of dissection. Now the originall of the Veines is in the lower region, at which we began our discourse. The originall of the Arteries in the middle region, and that of the Nerues in the vpper.

A veine therefore is by the latter Greeke writers absolutely called *φλέψ*, *Eudoxus* calleth it *ἐπανθισμός*, *Hesychius* *δρεζαμνν*, because it is the canale of the blood. The Ancient Physitions, as *Hippocrates*, vsed *φλέψ* as a common name to the veines and Arteries, so in his Booke *de carnibus*, There are two *κρῶλαι φλέβες*, saith he, two hollow veines issuing from the heart: the one is called a veine, the other an Arterie. Sometimes *Hippocrates* distinguisheth betwixt these two veines by adding the word *σφίγγειν*, which signifieth to beate, as if he should say Arteries are beating veines, veines those that doe not beate. Many places might be alledged to prooue this distinction if wee thought it needfull: *Auicenna* calls the Arteries beating and bold veines; *Cicero* *venas micantes* which doe sometimes lift vp themselves, and sometimes sinke againe. *Celsus* calleth them veines fitted for the spirits, and the true veines he calls *quietas*, still veines. *Hippocrates* is his Booke *de morbo sacro*, to distinguish the veines from the Arteries which are the conceptacles of the spirits calleth them *ἀραιαί φλέβες* bloody, because they conuey the blood. The names of veines.

The latter Grecians haue included this name within narrower bounds and restrained it onely to quiet or still veines which haue but one simple coate, in whose foote-steps wee also doe insist calling the arteries not *φλέβες*, but *ἀρτηρίαι*, so the vessels being distinct their names also are distinct.

Furthermore, the vessels are distinguished in their structure motion and vse. In the structure, because a veine hath a thin coate, whereas the coate of the Arterie is very thicke. In their motion, because an Arterie is mooued perpetually and conspicuously with a dilatation and systole, that is, a dilatation and contraction, whereas the veine is altogether immooueable. In vse because the Arterie transporteth the vitall spirit together with exceeding thin blood. The veines carry a thicker blood and a more cloudy spirit: the veins haue an inbred faculty to alter and boyle the blood: the arteries haue no such faculty, because their blood attaineth his vtmost elaboration and perfection in the heart. But let vs come to the definition of a veine. How veines & arteries differ.

A veine may be considered two manner of wayes, either as it is a Similar, or as it is an organically part. *Galen* in his 2. Booke *de Elementis* accounts it Similar, if not in deede, yet at least according to the iudgement of the sense; againe, in his Booke *de morborum differentiis*, hee proueth that it is organically, for he calleth Veines Arteries and Muscles organs of the first kinde and most simple organs. Two considerations of a veine.

If you regard a veine as it is a Similar part, then must you define it by his temper, (for the temper is the forme of the similarity, that I may so speake) to bee *A cold and drie part generated out of a slimy and following portion of the seede*. I sayde it was cold in respect of his As Similar.

his naturall temper, for otherwise by the contaction of the blood and the perfusion of the spirits it is very hot. And in *Galens* first Booke *de temperamentis*, it is sayd to be hotter then the skin.

As organically.

If you consider a veine as it is an organically part, then shall you define it to bee *A vessell long, round, excavated or hollowed like a reede, having but one end and that a thin coat, wouen with all kinds of fibres, arising from the liver, and appointed or set apart by Nature to containe, boyle and distribute the blood.* In this definition you haue the figure, composition, originall, use and action of the organ elegantly described. The roundnesse and cauity of the vessell expresseth the figure of the organ whereby a veine is distinguished from a nerue, for nerues haue onely pores but no sensible cauities. *Praxagoras* therefore was in an error and so are those that follow him, who call nerues *venas continuatas* continued veines.

The explication of the definition.

The simple and thin coate noteth the structure of the vessell, and discriminateth or putteth a difference betwixt a veine and an artery, for an artery hath a double coate, one outward and another inward, and if wee may beleue *Erophilus* it is five-fold thicker then a veine, because it containeth thinner and more spryghtfull blood, which if it were not concluded or shut vp within thicke wals would easily breake prison and vanish away.
